Comment: In light of the absence of startup and shutdown emissions information from the test run data relied on by EPA to set the proposed standards and the difficulty of collecting data from such brief operation periods, including data from CEMs, it is appropriate for EPA to set work practices for these events for boilers and process heaters. As discussed earlier, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . ." [Footnote: CAA § 112(h)(1); 42 U.S.C. § 7412(h)(1).] Gathering data from startup and shutdown periods would be challenging given the brief nature of these periods as well as the need to define the exact time period for what is considered "startup" and/or "shutdown." Moreover, the definition of "not feasible to prescribe or enforce an emission standard" is defined in the CAA as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." [Footnote: CAA § 112(h)(2); 42 U.S.C. § 7412(h)(2).] Attempting to measure combustion emissions while the boiler (or process heater) is in a state of flux does not lead to reproducible or reliable data and is not economically feasible. Startup and shutdown episodes, therefore, fit with this definition and would justify the agency setting work practices to address emissions during these periods. Furthermore, a work practices approach for these periods would be in keeping with the statute's requirement that MACT standards be "achievable" as well as with the requirement that a MACT standard apply at all times.

A work practices approach for these periods also would be consistent with EPA's recently promulgated MACT standards for compression ignition reciprocating internal combustion engines (CI-RICE). [Footnote: See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. 9648 (Mar. 3, 2010).] Based on comments received from stakeholders, EPA finalized work practice standards for startup because the agency determined that it was "not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations." [Footnote: See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 9656. (Mar. 3, 2010).] According to EPA, applicable test methods that would be needed to measure during these events "do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods." [Footnote: See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 9665. (Mar. 3, 2010).] Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. [Footnote: See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. 9648 (Mar. 3, 2010).] Startup and shutdown periods for boilers encounter similar testing challenges and costs. For these reasons, the Auto Group recommends that for startup and shutdown periods, EPA consider a work practices requirement similar to the approach used in the CI-RICE MACT noted above, that would limit these periods to three hours or require sources to comply with manufacturer specifications, if available.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 54

Comment: With respect to malfunctions, as noted earlier, EPA argues in the preamble to the proposed Boiler MACT that these periods should not be considered a "distinct operating mode" and uses this to justify not factoring these emissions into the proposed MACT standards. Considering that EPA's proposed MACT standards are supposed to apply at all times, the implication is that periods of malfunction also are covered by the MACT standards that apply during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable."

Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should set work practice requirements to address periods of malfunctions as well. As noted above, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . ." Similar to startup and shutdown, malfunctions fit with the situations described in the definition of "not feasible to prescribe or enforce an emission standard" as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Emission testing for malfunctions would be near impossible to conduct given the sporadic, short term, and unpredictable nature of the events. As noted earlier, EPA acknowledges in the preamble to the proposed Boiler MACT that it is "impracticable" to take periods of malfunctions into account when setting emissions standards given the "myriad different types of malfunctions that can occur across all sources in the category" and that "malfunctions can vary in frequency, degree, and duration, further complicating" the standard setting process. [Footnote: 75 Fed. Reg. at 32,013.] Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

For startups, boilers and process heaters need to be brought up to normal firing rates slowly, and three hours, as a default, is a sufficient period of time to ensure that the unit reaches the optimal firing rate without damaging the unit. With regard to malfunction periods, The Auto Group suggests that EPA require owners and operators to minimize emissions during malfunctions to the greatest extent practicable and follow safe operation practices.

Response: See the preamble for achievability of limits and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: When setting standards in the early 1990's under CAA 112(d), EPA used its New Source Performance Standards (NSPS) program as a model. The section 112 standards were acknowledged by EPA to be "essentially equivalent to [section 111] performance standards" and that "unpredicted and reasonably unavoidable failures of air pollution control systems" would occur. 58 Fed. Reg. 42,760, 42,777 (Aug. 11, 1993). To address this situation, EPA adopted a similar exemption to the one in the NSPS Program for SSM events and imposed a "general duty" to minimize emissions. Thus, EPA acknowledged, as early as 1993, that SSM events are not appropriate for inclusion in a MACT standard and that an alternative approach should be used to address these situations. While the D.C. Circuit has ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112, and so section 112(h) "work practices" or "operational" standards are available in certain situations. See Sierra Club v. EPA, 551 F.3d at 1028.
The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing NSPS under section 111 of the CAA, Portland Cement Ass'n v. Ruckelshaus, 486 F.2d 375, 398 (D.C. Cir. 1973), the court acknowledged that "'startup' and 'upset' conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." Id. at 399. Furthermore, in National Lime Ass'n v. EPA, 627 F.2d 416 (D.C. Cir. 1980), the court noted that "a uniform standard must be capable of being met under most adverse conditions which can reasonably be expected to recur." Id. at 431 n.46. The D.C. Circuit acknowledged this same principle almost 20 years later when reviewing emission standards for new sources in the medical waste incinerator rule under section 129 in Sierra Club v. EPA, 167 F.3d 658 (D.C. Cir. 1999). In that case, while the court did not find the record sufficient to support EPA's approach for new sources, the D.C. Circuit did not object to a standard-setting approach which would account for the performance of technology under the "worst reasonably foreseeable circumstances." See id. at 665. Furthermore, the D.C. Circuit reiterated the principle in National Lime that "where a statute requires that a standard be 'achievable,' it must be achievable 'under

the most adverse circumstances which can reasonably be expected to recur.'" Id. at 665 (citing National Lime Ass'n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980)).
EPA's MACT floor-setting approach in the Proposed Boiler MACT ignores these longstanding principles and mischaracterizes the role startup and shutdown data plays (or rather, does not play, as the case is here) in EPA's floor-setting process. As noted above, EPA claims that the agency considered startup and shutdown periods when setting the floors because CEMS data, relied on by EPA in "establishing the standards," included data from those periods. See Proposed Boiler MACT Rule at 75 FR 32012.

Comment: The following data is a subset of the data available to EPA within the docket. These excerpts reflect start-up and shutdown CO data from two facilities. One is a coal fired unit and one is a wood fired unit. Both data sets provide EPA data during periods of start-up and shutdown. While the absolute values are different in both cases the data indicates that carbon monoxide levels are up to twenty times greater during such periods. This is due to the influence of oxygen levels. When fuel values are low, as during periods of start-up and shutdown, oxygen levels are higher, making the corrected pollutant concentrations much higher. Further, as noted in the data set, the raw pollutant levels are elevated due to unstable combustion. [See submittal for to graphs showing CO and O2 levels during startup and shutdonw at a coal-fired and wood-fired boiler.]

If EPA had examined these data in some detail, it would have recognized two important aspects of the startup and shutdown periods. First, during startup periods, the oxygen content of the flue gas is generally very high, resulting in high calculated concentrations of pollutants, when they are corrected to 3 or 7 percent oxygen. Second, during shutdown periods many types of boilers continue to emit pollutants for some time while the fuel feed rate has gone to zero. Thus, during those periods the pollutant emission rates when measured in terms of the heat input rate would contain a zero in the denominator and would equal infinity. Combining emissions during shutdown periods with all operating periods would mean an emission limit of infinity. Based on this ridiculous outcome, we recommend that EPA exclude periods of startup and shutdown from its numerical standards and replace them with work practice standards aimed at minimizing pollutant emissions.
It is apparent that EPA did not consider this data when it established the proposed standards. In each of the cases present above, the proposed standards would have been exceeded during a 30 day period simply due to a start-up and shutdown condition. We believe that EPA should strongly reconsider this information before finalizing a standard.

Comment: Particulate matter is elevated during start-up or shutdown. Although data are not available in the data sets provided by EPA, the following hypothetical example demonstrates the effect. Using the above equation the following set of results can be calculated: [See submittal for table showing an increase in PM emissions (lb/mmBtu) when % O2 increases.]

In such situations it is very likely sources will exceed the proposed standards for several hours until combustion is stabilized. In this example, a start-up period of just a few hours would exceed the standard of 0.02 lb/MMBTU. Similar examples could be generated for the other pollutants regulated in the proposal, given more time to comment.
It is important to note that in the above scenario, the actual concentration emitted is held constant. In real situations this may not be the case. It is very common in industry for certain control devices to be out of operation during periods of start-up due to the nature of the equipment. Electrostatic precipitators (ESPs) must typically warm-up to be effective. This practice is necessary to ensure that boilers are started up in a safe manner. Premature starting of this equipment will lead to short term stability problems that could result in unsafe actions and longer term degradation of ESP performance due to fouling, increased chances of wire damage or increased corrosion within the chambers. Vendors providing this equipment make it part of the standard operating procedures. An example from a vendor manual is attached in Appendix I. During periods of start-up, combustion starts and as fuel is introduced the ESPs warm-up on a designated curve that could last for between 5 and 8 hours. As the control device is heated up additional fuel is added until the ESP meets its design temperature and normal fuel firing resumed. Like the example provided above, during such periods it is likely that emissions will exceed the standards proposed and would never be able to recover to meet the average limitations.

Comment: AF&PA applauds the fact that EPA is allowing the use of emissions averaging and common stack monitoring in its proposal. However, in the context of periods of start-up and shutdown, AF&PA does not see how either of these provisions would be particularly useful. For example, if a site has two boilers, one of which routinely achieves levels below the standard and one of which slightly above the standard, but averaged are able to achieve the required standard. It is unclear to AF&PA how these standards could be met during periods when the boiler with the lower emission rate is not operating. The problem is compounded when applied to a common stack where it is possible that different units could start-up and shutdown at differing times within an averaging period. Under these situations, it very unlikely that the proposed numeric limitations would be met First, for the reasons related to more than one unit with differing emission rates and second due to the start-up characteristics and inability to meet certain limitations largely due to the impact of oxygen levels.

Response: See the preamble for common stack monitoring and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Given the limited carbon monoxide data and total absence of startup and shutdown emissions information for other pollutants from the test run data relied on by EPA to set the proposed standards and the infeasibility, if not impossibility, of collecting data from such brief operation periods for other pollutants, it is appropriate for EPA to set work practices for these events for boilers and process heaters. Section 112(h) allows EPA to set work practice standards for situations where “it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . .” CAA § 112(h)(1); 42 U.S.C. § 7412(h)(1). Gathering data for other pollutants from startup and shutdown periods would be nearly impossible given the brief nature of these periods as well as the need to define the exact time period for what is considered “startup” and/or “shutdown” and the fact that CEM data would almost be required to collect such data that does not exist for a number of the pollutants proposed to be regulated. Moreover, the definition of “not feasible to prescribe or enforce an emission standard” is defined in the CAA as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” CAA § 112(h)(2); 42 U.S.C. § 7412(h)(2). Startup, shutdown, and malfunction episodes fit squarely within this definition for the reasons outlined above and would justify the agency setting work practices to address emissions during these periods. Furthermore, a work practices approach for these periods would be in keeping with the statute’s requirement that MACT standards be “achievable” as well as with the requirement that a MACT standard apply at all times.

Comment: A work practices approach for these periods also would be consistent with EPA's recently promulgated MACT standards for compression ignition reciprocating internal combustion engines (CI-RICE). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, Final Rule, 75 Fed. Reg. 9648 (Mar. 3, 2010). Based on comments received from stakeholders, EPA finalized work practice standards for startup because the agency determined that it was "not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations." Id. at 9656. According to EPA, applicable test methods that would be needed to measure during these events "do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods." Id. at 9665. Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. See id. Startup and shutdown periods for boilers encounter similar testing challenges and costs.
A work practices approach for startup and shutdown is also supported by the recent draft ICR for pulp and paper sources (EPA-HQ-OAR-2007-0544-0003 ,pulp and paper survey overview). In that action EPA is proposing to collect information on the following:
Questions pertaining to emission unit startup and shutdown are asked in order to provide EPA with an understanding of the duration, emissions potential, work practices, and control mechanisms of startup and shutdown events for the wide variety of equipment used at pulp and paper mills. The EPA is considering standards that could apply during startup and shutdown events (or whether the current standards developed for normal operation should apply) in light of the December 2008 vacatur of the NESHAP startup, shutdown, and malfunction exemption in 40 CFR Part 63 subpart A.
Here clearly EPA is interested in understanding more about actions and work practices that are employed currently in order to determine the appropriate course of action in establishing standards during such periods. It is not clear why EPA would not consider this same type of information in relation to boilers and process heaters.

Comment: EPA argues in the preamble to the Proposed Boiler MACT states that malfunction periods should not be viewed as a "distinct operating mode," and thus, emissions from these periods do not need to be factored into developing the MACT floor levels. See id. Moreover, EPA states that even if malfunctions were to be considered a distinct operating mode, it would be "impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters" given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration. Id.

Considering that EPA's proposed MACT standards are supposed to apply at all times, the implication is that periods of malfunction also are covered by the MACT standards that apply during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable." EPA has failed to recognize that it is likely that even best performers will experience malfunctions. It is possible for pollution control equipment to fail in various ways. Electrostatic fields trip, power failures do occur, fabric filters fail, scrubber pumps fail even at best performers and despite the best efforts of companies to prevent and minimize such events. Industry can and does work to minimize such periods, but they do occur. Further, manufacturers of such equipment routinely make emission guarantees for normal operations and although they sometimes oversize equipment to account for some of the variability described above, it is very doubtful that vendors would provide sufficient numerical guarantees for equipment under such situations.

Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should set work practice requirements to address periods of malfunctions as well. As noted above, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . ." Similar to startup and shutdown, malfunctions fit with the situations described in the definition of "not feasible to prescribe or enforce an emission standard" as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. As noted earlier, EPA acknowledges in the preamble to the Proposed Boiler Rule that it is "impracticable" to take periods of malfunctions into account when setting emissions standards given the "myriad different types of malfunctions that can occur across all sources in the category" and that "malfunctions can vary in frequency, degree, and duration, further complicating" the standard setting process. Proposed Boiler MACT Rule at 32,013. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

For these reasons, AF&PA believes that it is appropriate for EPA to revisit this issue. AF&PA suggests that EPA propose work practice standards that would allow sources a certain time period for start-up, shutdown and malfunction events and as long as certain procedures are followed, then compliance would be met. Those work practice standards should require the development and implementation of an emissions minimization plan that will result in (a) minimizing emissions during such events that would exceed otherwise applicable emission limitations, and (b) for malfunctions that will cause the unit to exceed otherwise applicable emission limitations, promptly identifying and implementing measures to remedy the malfunction. While there may be some instances where standard work practices can be identified for a type of source, AF&PA cautions that overly prescriptive and non-facility-specific requirements can actually be counterproductive, restricting the operators' flexibility in a way that hampers their ability to troubleshoot or respond to an event, or that compromises safety. The plan itself should not be incorporated into the Title V permit. The plan should be an evolving document, and it would be very cumbersome to have to seek a modification of the Title V permit every time the plan changed. If the details of the emissions minimization plan had to be made part of the permit, facilities would tend to make the plans less specific and therefore probably less useful. For the same reason, these plans should be maintained at the facility rather than being required to be submitted to the permitting authority with the Title V application or otherwise.

Comment: Sources will not be able to meet some operating parameter limits on startup.
As stated in the comments related to appropriate averaging times and related to startup and shutdown, many types of control equipment are not in full operational mode while a boiler is starting up. Therefore, operating parameter limits will not always be feasible to meet during startup. EPA should instead establish work practices for the startup period, in lieu of requiring operating parameter limits to be met.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Stephen R. Gossett

Comment: EPA should establish work practice standards instead of numerical emissions standards for boilers and process heaters operating during periods of startup and shutdown.

It is inappropriate to require compliance with numerical emissions standards that are achievable during periods of steady-state operation during periods of startup and shutdown. Institutional, commercial and industrial boilers, like their larger Electric Generating Unit (EGU) analogs, require an extended period of startup during which most, if not all, equipment in the boiler and pollution control systems are not operating in their normal condition. This extended startup period, typically several hours, is required due to equipment integrity concerns, limitations of the technologies, or safety concerns:

* Equipment Integrity – For example, a Fabric Filter (FF) cannot be put into service until the flue gas temperature is above the dewpoint. This requires that all heat transfer surfaces, ducts and flues from the combustion zone to the FF inlet be warmed up from ambient temperatures to dewpoint temperature (which varies by fuel type and fuel constituents, but is typically in excess of 140oF / 60oC). It takes a considerable amount of time, typically several hours for larger units, to warm up this considerable mass of steel: waterwall tubes, superheater tubes, reheater tubes, economizer tubes, casings, turning vanes, air preheaters, ducts and inlet plenums. During this warmup period, the FF cannot be put into service without risking catastrophic failure of the bags and intensive corrosion damage to the FF. This limits a unit's ability to control particulate matter and mercury during the several hours of startup.
* Limitations of the Technology – For example, units equipped with a Spray Dryer Absorber (SDA) for acid gas removal are limited in the amount of reagent slurry that can be injected into the flue gas during startup. The slurry federate is limited due to the nature of the technology by the amount of moisture the flue gas can evaporate. This in turn requires that a minimum temperature be achieved by the flue gas before the slurry federate can be initiated, and imposes a lengthy period of time during which the slurry federate is significantly limited until all the upstream heat transfer surface and ductwork has been warmed up. As such, SDA cannot remove Hydrogen Chloride in significant quantities for several hours after the unit is first fired.
* Safety Concerns – For example, reductions in the amount of time required to warm the boiler system up could be realized by increasing the ramp-rate of adding fuel to the unit. In theory, a boiler could be brought from first flame to full load in a matter of minutes, but decreasing the warm-up period from what the OEM recommends risks severe metallurgical stresses due to rapid changes in temperature and wide variances in temperatures across boiler and duct parts. Immediate failures could occur if inconsistent heating caused tears or ruptures in support steel or heat transfer surfaces, posing considerable risk to personnel in the plant. Failure rates would also increase due to the considerable stresses introduced by rapid heating and cooling cycles, yielding

failures at unpredictable times (steady state operation or future startups or shutdowns). For this reason, OEM recommendations for startup times are closely followed across industry.

EPA makes a mistaken assumption that startups and shutdowns are "predictable and routine". Industrial facilities, unlike electric utilities, typically operate a large number of smaller units of Eastman Boiler MACT Comments varying ages instead of operating a small number of very large units. When normal equipment failure rates (e.g., tube leaks) are multiplied across a large number of units, the total number of unit failures can be significantly larger at industrial facilities. Eastman operates a facility with over a dozen boilers, which average more than two unplanned outages per unit above and beyond each unit's planned outage in any given year. It is not uncommon for unplanned outages to occur in clusters, such as when a given component (e.g., an economizer) might suffer a failure due to corrosion or erosion. Repairs may fix the failure of any identified vulnerable areas nearby, but the root cause of the failure could be occurring in multiple areas that are not easily identified, resulting in additional failures in a short timeframe.

Comment: EPA should establish work practice standards issued under section 112(h) of the Clean Air Act to ensure emissions are minimized during startups and shutdowns without unreasonably requiring sources to attempt to comply with steady-state emission standards. EPA should add provisions to require sources to develop and adhere to operating practices specific to the unit's design, fuel type, and OEM recommendations that will ensure emissions minimization without forcing owner/operators to choose between putting their equipment and personnel at risk versus failing to comply with this rule. Such an operating practice should be crafted to be flexible, given the wide variety of boiler sizes, types, vintages, and fuels fired, and should be developed by the source based on OEM recommendations. General guidelines could include:

• Sequencing of equipment startups, per OEM recommendations
• Startup time durations, per OEM recommendations, and
Provisions to clearly define what constitutes "online" versus "startup". This could be crafted to mean a percentage of the unit's maximum continuous rating, or steam temperature/pressure, etc.

Comment Excerpt Number: 49

Comment: Eastman notes that EPA followed a work practice approach in its final rule for Reciprocating Internal Combustion Engines (RICE) issued on March 3, 2010. There, EPA concluded "it was not feasible to prescribe a numerical emission standard for stationary CI engines during periods of startup because the application of measurement methodology to these engines is not practicable due to the technological and economic limitations described below." (75 Federal Register 9665). Many of the reasons EPA articulates for this decision apply to the boiler and process heater source category regarding the accuracy of the stack gas sampling methods during transient load cases like startup. Eastman recognizes that EPA has set work practice standards in the RICE rule by limiting startups to 30 minutes. We agree this is appropriate. However, when it comes to boilers and process heaters, it is a much more complicated issue. Given the variety of units, operating pressures and temperatures, etc., we do not believe it is practical to set startup and shutdown periods on a "one-size fits all" basis. Rather, each source should work with their permitting authority to establish and obtain approval of appropriate work practice standards.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: W. Randall Rawson
Commenter Affiliation: American Boiler Manufacturers Association

Comment Excerpt Number: 3

Comment: In establishing achievable MACT emission standards, EPA should address the anticipated startup, shutdown and malfunction conditions that may be experienced across the wide range of boiler designs and applications. To the extent that emission standards must apply during periods of startup, shutdown and malfunction, they must be set in a manner which adequately accounts for anticipated emissions during those conditions. ABMA is concerned that the data on which EPA has relied does not adequately represent considerations that may affect such emissions, such as boiler size, usage of flue gas recirculation ("FGR"), steam pressure and temperature. These issues are particularly relevant to startup conditions, which are reasonably anticipated and can be evaluated in the standard-setting process. For example, the following factors should be considered in relation to CO emissions during startup:

* During cold start, furnace temperature is low and higher CO emissions will result;
* High pressure boilers take longer to come up to temperature;
* Super heated steam applications take longer to reach their normal operating conditions;
* Low NOx, high FGR applications have very low air velocities at the burner during cold start, because FGR cannot be introduced to the burner before it reaches a certain temperature, thereby reducing volumetric flow and resulting in higher CO emissions;

* A typical cold start CO emission level that may range up to 400 ppm or higher on oil, and the following wide range of boiler warm-up periods based on boiler type may result in significantly higher average CO emissions than experienced at steady-state operation: [Footnote: For example, assume a typical industrial water tube low NOx gas burner application mounted on a super heated steam boiler may achieve 15 ppm CO at steady state operation. Conservatively assuming a four hour warmup period during which 200 ppm is experienced for the first two hours of startup and 100 ppm for the second two hours, the 24 hour average emission would be 200 ppm x 2hr/24hr + 100ppm x 2hr/24hr + 15 ppm x 18hr/24hr = 36.25 ppm.]

Firetube boilers: 1-4 hours
Industrial watertube boilers (150 psig): 3-6 hours
Super heated industrial watertube package boiler: 4-8 hours
Super heated field erected boilers – 8 hours or more

Comment: EPA's preamble to the Proposed Boiler MACT does acknowledge an attempt to incorporate startup and shutdown emissions through its consideration of daily or monthly average CEMS data from the best performing units. However, EPA has not demonstrated that its data set adequately addresses the variability in startup length and associated emissions experienced in boilers of various design and load requirements. Therefore, ABMA believes that EPA should: (1) allow a period of time for startup, based on boiler type, during which emissions limits would not apply; (2) establish an alternative emission limit for startup periods based on boiler types within a subcategory and their load; or (3) review the data set and the anticipated startup conditions of various boiler types to ensure that the emission limits set for each subcategory are representative of multiple boiler designs and emission variability within the subcategory. The alternatives for defining reasonable emission standards for startup conditions should extend to startups occasioned by the range of circumstances, such as cold start after a period of scheduled non-operation, as well as startup occurring after a malfunction during which cold-start parameters often apply. Additionally, EPA should extend similar consideration to emissions variability during shutdown periods. During these periods, considerable volumetric post- and pre-purge air change requirements serve to cool boilers down in an attempt to relieve the combustion chamber of unburned fuel and of flue gases prior to re-ignition sequence.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: ABMA also supports a limited allowance for malfunction periods. The term "malfunction" should be more precisely defined to include the variabilities of malfunction. Malfunction can range from the need for immediate and complete shutdown to malfunctions like an interruption in fuel supply or an inoperative CEMs that will require only a short downtime. A plant should not be required to completely shutdown due to a malfunction of the boiler, burner or boiler-related equipment. Once defined, a malfunction should be regulated by alternative limits applied during the time it takes to complete corrective action and get the boiler back to normal operational mode.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA Has Not Adequately Provided for SSM Events. EPA states it has taken into account startup and shutdown periods in setting MACT limits because data used in setting the standards includes periods of startup and shutdown and because the averaging times are daily or monthly periods. 75 Fed. Reg. at 32013. Therefore, EPA concludes no special limits are needed for startup and shutdown which it says are predictable and routine. However, EPA has not shown that the data on which it relies actually includes meaningful data from startup and shutdown events. Certainly stack test data, by definition, is obtained during representative conditions and does not include startup and shutdown events. To the extent EPA relied on CEMS data for PM or CO, it is not evident that such data included meaningful data for startup or shutdown events. Further, EPA's assumption that boilers do not normally startup or shutdown more than once per day is not accurate for many boilers which may start up multiple times in a day. As noted above, the practice for at least some soda ash facilities is that during startup the ESP does not come on line until the exhaust temperature reaches 350F, which means that PM emissions during that time are not the same as during normal operations. The result is that the proposed MACT limits do not represent what is "achievable" during startup and shutdown, contrary to Section 112(d) of the Clean Air Act and Sierra Club v. EPA, 167 F.3d 658, 665, supra.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 7

Comment: EPA correctly recognizes that malfunction events are not predictable or routine aspects of a facility's operation and that malfunction emissions, therefore, do not have to be factored in to the MACT limits. EPA's proposal for dealing with malfunctions that result in a failure to comply with MACT limits is to "determine an appropriate response based on, among other things, the good faith efforts of the source to minimize emissions during malfunction periods , including preventative and corrective actions, as well as root cause analyses . . ." No provision for malfunctions is actually included in the proposed rule itself. To the contrary, Table 6 of the rule states that standards must be met at all times, including malfunctions. It is unreasonable to expect sources to rely on preamble language that is contradicted by the rule itself, and that provides for an entirely subjective after-the-fact judgment, as a satisfactory malfunction provision. If, as the EPA admits, the limits were set without taking malfunction events into account, and if malfunctions are neither avoidable nor predictable, the only satisfactory approach is to excuse noncompliance that results from malfunctions if reasonably defined requirements are met. One way to accomplish this would be to require sources to develop malfunction plans and excuse emission exceedances due to malfunction if the plans are followed.

Comment: EPA's proposed requirement that facilities meet steady-state standards during SSM events is not logical nor is it lawful.

EPA's proposal to require industrial boilers and process heaters to'comply with the same emission standards during periods of startup, shutdown, malfunction, and steady state conditions is neither logical nor lawful.

Before the court's decision in Sierra Club v. EPA, 551 F.3d 1019 (DC. Cir 2008) ("SSM Decision") the DC Circuit had consistently held that technology-based standards must contain exemptions or less stringent standards during periods of startup; shutdown, and malfunction (SSM) than would usually apply during steady state periods.

For example, in Portland Cement Ass’n v. Ruckelshaus, 86 F.2d 375, 396, 398 (D.C. Cir. 1973), cert. denied, 417 U.S. 921 (1974) ("Portland Cement"), the DC Circuit recognized that "‘start-up’ and ‘upset’ conditions, due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated. The Court, which was addressing EPA’s NSPS rules, also noted that including the startup, shutdown, and malfunction provisions "imparts a construction of ‘reasonableness’ to the standards as a whole and adopts a more flexible system of regulation than can be had by a system devoid of ‘give." Id. at 399.

In Essex Chem. Corp. v. Ruckelshaus, 486 F.2d 427, 432 (D.C. Cir. 1973); petitioners argued that lesser or no standards should apply during startup, shutdown or malfunction conditions. The Court agreed, holding that such provisions "appear necessary to preserve the reasonableness of the standards as a whole." Id. at 433. And in NRDC v. EPA, 859 F.2d 156 (D.C. Cir. 1988), the court held that, although water-quality permit limits need not incorporate an "upset defense," "[a] technology-based standard discards its fundamental premise wheh it ignores the limits inherent in the technology." Id. at 208 (citing Marathon Oil. Co. v. EPA, 564 F.2d 1253, 1273 (9th Cir. 1977)). Consequently, because all pollution control technologies will occasionally malfunction and take time to get to their steady-state conditions (such as during startup, shutdown or malfunction), "achievable" technology-based standards must contain provisions for compliance during such unavoidable events.

Now that the court has decided that MACT compliant standards must apply during periods of SSM, the Agency must develop standards that are "achievable" with this ruling in mind. The court has stated that for standards to be "achievable," they must be achievable under the most adverse circumstances which can reasonably be expected to recur, Sierra Club, supra, 665 citing National Lime Ass’n v. EPA 627 F2.d 416 (D.C. Cir. 1980) ("National Lime 1’). Consequently, since startup, shutdown, and malfunctions will recur, EPA must set standards that must be achievable during those times.

The standards EPA are proposing for industrial boilers and process heaters are not capable of being complied with during periods of SSM. For example, facilities with baghouses cannot comply during startup periods because they have to bypass the bags until the temperature gets above the condensation point. Otherwise, they will prematurely damage their bags. There are similar issues for other types of air pollution control devices. Despite this, EPA states in the preamble that they have taken into account startup and shutdown periods in establishing these standards (75 FR 32012) and is not establishing different standards for these periods (75 FR 32013). EPA’s reasons are that boilers do not normally startup or shutdown more than once a day and that daily or monthly averages are used to show compliance with the standards. EPA is correct that boilers typically do not startup more than once a day perhaps because it may take 36 to 48 hours to startup a large boiler (required time to heat up the refractory to avoid equipment damage). The major flaw in EPA’s reasoning, however, is that EPA did not include emissions data during either startup or shutdown in the development of these standards; all data collected was under steady-state conditions. Since emissions under non-steady-state conditions may vary significantly, they could significantly alter the Agency's calculations. Thus, the standards are not properly set.

In addition, EPA does not consider a malfunction as a distinct operating mode. CRWI disagrees. Malfunctions occur. Just because EPA states that the goal of best performing sources is to have no malfunctions (75 FR 32013) does not make malfunctions go away. Even the best operated and maintained facilities will have malfunctions. For example, any facility that is tied into the external electric power grid (most have at least a small tie-in) will face power disruptions potentially causing malfunctions. We have all lost power in our homes at one point in time — it's an inevitable.

We agree, however, that it is difficult to develop the data necessary to set numerical emissions limits for transient conditions. For example, if a facility ran a Method 5 test during startup, a single test would take 6 — 8 hours (each run takes at least an hour, three runs are required for a valid test, and the operator must have time in between runs to change out sampling equipment). During those eight hours, the conditions would have changed so significantly that it would be virtually impossible to understand what that data meant or to extrapolate that data to other transient conditions. The same is true for CEMs readings.

As such, EPA must establish, and explain why facilities can comply with the standards it promulgates. As the court noted in National Lime I, "by failing to explain how the standard proposed is achievable under the range of relevant conditions which may affect the emissions to be regulated, the Agency has not satisfied this initial burden." National Lime I, supra, at 433.

So, while it is appropriate to use data gathered under steady-state conditions to set emission standards for steady-state conditions, it is not appropriate (from either a logical or legal perspective) to apply those standard's to non steady-state conditions. Thus, EPA must find an alternative method for facilities to show compliance during these phases of operation. Congress provided for this when they set up the work practice provisions of 112(h). Here Congress stated that EPA may set work practice standards if it is not feasible to prescribe or enforce an emissions standard. CRWI believes that it is infeasible to gather data during startup, shutdowns, or malfunctions simply because there are no EPA approved methods to, make measurement during non-steady-state conditions and malfunctions, by definition, are sudden and infrequent. In the final Hospital/Medical/Infectious Waste Incinerator rule, EPA agrees with this. At 74 FR 51394, EPA states "It would be very difficult to do any meaningful testing during such an event because the exhaust flow rates, temperatures, and other stack conditions would be highly variable and could foul up the isokinetic emissions test methods (thus invalidating the testing)." The obvious choice for these conditions are work practice standards.

In summary, standards developed under steady-state conditions cannot incorporate the variability that occurs during SSM events. Expecting a facility to comply with emission standards developed under steady state conditions during SSM events is neither logical nor lawful. Thus, EPA should modify the proposed regulatory language to require facilities to meet emission standards (derived from data gathered understeady-state conditions) during normal operations. In addition, CRWI suggests EPA set work practice standards for startup, shutdown, and malfunctions. This would satisfy both Congress' intent that 112 standards apply at all times and the recent court ruling. Alternatively, EPA could gather data during startups, shutdowns, and malfunctions and incorporate this data into the data gathered during steady-state conditions to set numerical emission standards. Emissions standards based on data collected during all modes of operation could then reasonably apply at all times.

Comment Excerpt Number: 9

Comment: EPA needs to allow an alternate oxygen correction factor during these events. During the first part of startup and the last part of shutdown, the oxygen concentrations will approach ambient concentrations. When this occurs, the equation used to calculate the correction factor will approach infinity (dividing by - zero). Under these conditions, it is not appropriate to apply the oxygen correction factor as proposed. The HWC MACT rule allows facilities to set up an alternate correction factor for these conditions. One example of how this problem can be addressed can be found at 40. CFR 63.1206(c)(2)(iii).

Comment: If EPA keeps the provisions that the facility must comply with the standards are all times, CRWI sees no reason facilities have to record and report "SSM" events. The proposed language contains some inconsistencies. For ‘ example, Table 10 proposes that the requirement to develop an SSM plan does not apply. fn addition, EPA also proposes an immediate report if the facility does not follow their SSM plan. Since Table 10 proposes that the requirement to develop SSM plans (§ 63.6(e)(3)) does not apply, a facility cannot fail to follow a plan it is not required to have. CRWI suggests that EPA re-examine the proposed rule for any provisions that are inappropriate, unnecessary, or redundant should EPA remove the SSM provisions in the final rule.

Comment: The proposed Boiler MACT standard includes limits that apply at all times when it is likely that startup, shutdown, and malfunction emissions will be higher. Work practice standards for boiler startup, shutdown, and malfunction would be more effective and realistic (40 CFR 63.7500(a), 75 FR 32012). The proposed rule sets emission limits that apply at all times (40 CFT 63.7500(a), 75 FR 32012). This approach compounds the concern that CO emission limits have been set too low for realistic operations, based on inadequate data that reflect a limited group of very new units that is not representative of normal boiler performance. As a result, the proposed rule potentially creates a large number of units that are trapped with unachievable emission limits. A better solution would be for individual boilers to establish work practice standards for periods of startup, shutdown, and malfunction. The use of such standards, when focused on industry- and facility- specific work practices, provides for emission limits and effective control consistent with boiler design factors.

Comment Excerpt Number: 18

Comment: With due consideration to safety and operational requirements, some of the pollution control equipment (such as baghouses) of already permitted sources are designed to have different procedures of operation during SSM events. As a consequence, these sources will not be able to comply with the proposed standards during SSM events.

Per Section 63.7505(a), the standards set forth in the rule apply at all times. There is no specific allowance for SSM periods relative to the emission limits in the rule. EPA discusses in section III.E. on page 32012, that startup and shutdown periods were taken into account when setting the standards which are daily or monthly averages and thus achievable even when a startup or shutdown occurs. However, in Tables 1 and 2 of the proposed rule, carbon monoxide is the only pollutant for which an averaging period is specified. The emission limits for particulate matter does not appear to be based on an average over a time period. This is an unachievable standard since some pollution control devices cannot be in service until temperatures rise and conditions stabilize, during which emissions are known to exceed such low emission limits.

For example, a DoD facility operates baghouse control devices that must be bypassed during startup and shutdown due to explosion risk. This requirement is a documented standard operating procedure implemented at the facility and is based on recommendations of the equipment manufacturer. Because of these requirements for safety considerations, the Agency should adopt procedures similar to what was done in the Miscellaneous Organic Chemical Manufacturing NESHAP (40 CFR Part 63, Subpart FFFF [40 C.F.R. § 63.2450(q)]. This provision allows facilities that cannot meet an emission limit for safety reasons, to submit documentation in their precompliance report explaining why an undue safety hazard would be created if the air emission controls were installed, and to describe the procedures that you will implement to minimize HAP emissions from these vent streams. This provision is provided where it is unsafe to control the source at any time but it could be used as a model in the boiler rule to allow sources to avoid control during startup and shutdown when safety issues prevent use of controls.

The final rule should contain a provision similar to 40 CFR Part 63, Subpart FFFF, 63.2450(q) to exclude SSM events from the emission limits when it can be demonstrated that it is necessary to bypass emission controls for safety reasons.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 19

Comment: EPA should provide an affirmative defense for start-up, shutdown, and malfunction. Luminant opposes EPA's proposal to omit from the rule an affirmative defense for excess emissions of HAP during periods of start-up, shutdown, and malfunction ("SSM"). EPA's proposed rule unnecessarily disregards the special circumstance of excess emissions of HAP during SSM, and its omission would be an over-reaction to the D.C. Circuit's decision.

Citing the D.C. Circuit's opinion vacating the SSM exemptions in the "General Provisions Rule" of 40 C.F.R. §§ 63.6(f)(1) and (h)(1) (which exempted sources during periods of SSM from compliance with the emission standards), EPA has "established standards in [the proposed] rule that apply at all times." 75 Fed. Reg. 32,006, 32,012 (June 4, 2010), (citing Sierra Club v. EPA, 551 F.3d 1019 (D.C. Cir. 2008). In the case cited by EPA, the D. C. Circuit was reviewing a challenge to an SSM exemption and read §§ 112 and 302(k) of the CAA together to conclude that "Congress has required that there must be continuous section 112- compliant standards," and that "the SSM exemption [in the General Provisions] violated the CAA's requirement that some section 112 standard apply continuously." 551 F.3d at 1027-28 (emphasis added). However, EPA has gone well beyond the D.C. Circuit's holding, by not only providing no SSM exclusions, but also by offering no alternative provisions addressing excess emissions during periods of SSM.
EPA concludes in the proposed rule that because startup and shutdown are part of a source's "routine operations," these periods are "already addressed by the standards."

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 20

Comment: With respect to malfunctions, the proposed rule states that if a source fails to meet the applicable standards as a result of a malfunction, "EPA would determine an appropriate response based on, among other things, the good faith efforts of the source to minimize emissions during malfunction periods, including preventative and corrective actions, as well as root cause analyses to ascertain and rectify excess emissions." Id. EPA should actually incorporate that intent into the rule, by expressly including an affirmative defense available to sources during periods of SSM.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 21

Comment: Consistent with EPA's guidance on SSM, EPA's proposed rule should include an affirmative defense during periods of SSM. Specifically, EPA should provide that, while periods of excess emissions during startup and shutdown might be considered violations, an owner could raise an affirmative defense. EPA has recognized that "for some source categories, even the best available emissions control systems might not be consistently effective during startup or shutdown periods."[Memorandum from Steven A. Herman, Assistant Administrator for Enforcement and Compliance Assurance and Robert Perciasepe, Assistant Administrator for Air and Radiation, to Regional Administrators, Regions I – X, State Implementation Plans: Policy Regarding Excess Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999) ("1999 Policy").] The operational realities of excess emissions during periods of SSM have been acknowledged by EPA in several instances. For example, in EPA's new source performance standards, EPA provides that opacity standards apply "at all times except during periods of startup, shutdown, malfunction, and as otherwise provided in the applicable standard." 40 C.F.R. § 60.11(c); see also 75 Fed. Reg. 10,174 (Mar. 5, 2010) (approving a source-specific federal implementation plan for the Navajo Generating Station that provides an affirmative defense against penalties resulting from non-compliance during periods of startup, shutdown, and malfunction.).

Including an affirmative defense is also consistent with EPA's policy regarding exclusions during periods of SSM. Unlike an exclusion, an affirmative defense does not excuse a source from continuous compliance. The affirmative defense – when established by the source – merely relieves the source of any penalty imposed as a result of non-compliance during a period of SSM. It does not relieve the source of the requirement to comply with the applicable standard.

Finally, EPA has recently approved similar affirmative defense provisions in several states' State Implementation Plans ("SIP"). For instance, in Colorado, EPA approved a SIP provision providing an affirmative defense during periods of startup and shutdown. See, e.g., 71 Fed. Reg. 8958 (Feb. 22, 2006). Similarly, EPA approved an affirmative defense in New Mexico's SIP for excess emissions during startup, shutdown, and malfunction related activities. See 74 Fed. Reg. 46,910 (Sept. 14, 2009). When EPA approved the Colorado and New Mexico revisions, it stated that the affirmative defense provisions were consistent with its 1999 policy provisions. See 71 Fed. Reg. at 8959; see also 74 Fed. Reg. at 46,912 (The "SIP submittal contains criteria to be considered when asserting an affirmative defense for an excess emission during startup or shutdown . . . that are similar, if not identical, to those in the 1999 Policy.”).

Nothing in the D.C. Circuit’s opinion precludes EPA from including an affirmative defense for excess emissions during periods of SSM. In fact, doing so would be consistent with 1) EPA’s recognition of various operational reasons a source might be in non-compliance; 2) EPA’s policy against exclusions (or similar provisions abrogating the CAA’s requirement to be in continuous compliance); and 3) EPA’s approval of similar SIP provisions. Accordingly, Luminant urges EPA to include an affirmative defense in the final rule.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 38

Comment: CIBO notes that not all these data sets include periods of startup. In the stoker coal subcategory, the unit at DuPont in West Virginia did not note any periods of SSM in the CO Monitoring Template. Further, EPA’s graph of the CO CEMS data plotted vs boiler load for the Phillip Morris boiler in Virginia (the only pulverized coal boiler with CEMS data in EPA’s dataset) (see Appendix B-1 of the MACT floor memorandum) is wrong (it appears to plot the Excel row number vs. CO) and does not include data from boiler load below 100 MMBtu/hr. This boiler went through three startups during the 30 day period and the graph clearly shows elevated CO during low load periods and shows an inverse relationship of CO and boiler load. The average CO concentrations during periods of only "normal" operations was 35 ppm whereas the average CO concentrations during all periods (normal, shutdown, startup) was 27 ppm.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 39

Comment: EPA uses short term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction.

To assure that startup, shutdown, and malfunction are appropriately accommodated, EPA must either ensure that the data on which the standard is based include representative data from such periods or, alternatively, set a separate work practice standard to properly accommodate startup, shutdown, and malfunction. Lastly, instead of using the UPL, EPA should use the upper tolerance limit ("UTL"), which is meant for use in situations where the available data does not represent the entire population.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 40

Comment: Additional concerns with SSM events and the proposed rules are as follows:

* Daily average for opacity is not adequate to cover SSM in situations where control device cannot operate until a certain flue gas temperature is reached.
* Sometimes cannot start control device before certain exhaust gas conditions are met during startup.
* EPA cannot assume that units only startup or shutdown once per day. Bagasse boilers sometimes startup/shutdown several times a day.

It is unlikely that boilers will be able to comply with the promulgated standards at all times, including startup and malfunction. This is especially true for CO, since CO emissions are a function of combustion efficiency, which is lower during startup and malfunction events.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 41

Comment: Enforcement of malfunction events should not be carried out on a case-by case basis. This would cause undue burden on the regulatory agencies. Consistent with other Clean Air Act (CAA) regulations [i.e., New Source Performance Standards (NSPS)], malfunction events should be excluded from meeting the emission limits. Absent any exclusion, a higher emission limit based on actual operation should be set, which applies only during malfunction events and is reflective of malfunction events.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc

Comment: To address the decision in Sierra Club v. EPA, 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010), which vacated the exemption in 40 C.F.R. 63.6(f)(1) and (h)(1) for SSM periods, EPA proposes emissions standards in the MACT for industrial boilers and process heaters that apply at all times, including periods of malfunction, as well as startup and shutdown. For standards where EPA sets numeric limits, EPA must either; 1) treat malfunction as part of normal operating mode and then include the emissions during malfunction as part of the variation of the units emissions, or 2) treat malfunction as a distinct operating mode and establish work practices for malfunction periods.

In the preamble, EPA states malfunctions should not be viewed as a “distinct operating mode,” and thus, “emissions from these periods do not need to be factored into developing the MACT floor levels.” 75 Fed.Reg. 32013. EPA goes on to say:

For example, we note that Section 112 uses the concept of ??best performing“ sources in defining MACT, the level of stringency that major source standards must meet. Applying the concept of ??best performing“ to a source that is malfunctioning presents significant difficulties. The goal of best performing sources is to operate in such a way as to avoid malfunctions of their units. Id.

EPA‘s explanation is internally inconsistent. The statement that the goal of best performing sources is to avoid malfunction recognizes that best performing sources do occasionally malfunction. If malfunction is part of the regular operating mode of boilers and process heaters, then it should be part of the variation of the best performing units and included as part of the development of the floor.

EPA goes on to state that even if malfunctions were to be considered a distinct operating mode, it would be impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration. Id.
This however does not relieve EPA of its obligation to set standards that are achievable under Section 112(d)(2). A numeric standard that governs malfunction periods, but does not take malfunction emissions into account, is not achievable.

Consequently, EPA should set work practice requirements to address periods of malfunction. As noted above, section 112(h) allows EPA to set work practice standards for situations where “it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard…” Malfunctions fit within the situations described in the definition of “not feasible to prescribe or enforce an emission standard” as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. As noted earlier, EPA acknowledges in the preamble to the Proposed Boiler Rule that it is “impracticable” to take periods of malfunctions into account when setting emissions standards given the “myriad different types of malfunctions that can occur across all sources in the category” and that “malfunctions can vary in frequency, degree, and duration, further complicating” the standard setting process. Id. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

Recommendation: EPA should adopt work practices for malfunction periods for any numeric standard.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: According to 63.7505, the requirements of the proposed rule apply at all times. However, it is clear that no turndown, startup and shutdown emissions data were included in the database used to generate the proposed emission limits and that boilers and process heaters cannot meet all of the proposed emission limitations during all periods of turndown startup and shutdown. In fact, it is forbidden by 63.7(e) of the Part 63 General Provisions for performance tests to include startup, shutdown or malfunction periods in performance tests, so it is impossible to demonstrate compliance during such periods, even if a unit might be able to meet the proposed emission limits. Even units that can be retrofitted with controls that allow achieving the emission limits during normal operations will be unable to meet the limits during turndown operations and some startups and shutdowns because many of the controls are not effective at the low stack temperatures that occur during high turndown, startup and shutdown periods.

On page 32013 of the preamble, EPA explains the reasons it feels startup and shutdown activities are “normal” operations and thus are not handling startup and shutdown periods differently.

For gas-fired units, EPA collected two 30 day sets of CEMS CO data. It is ridiculous to claim this insignificant amount of data establishes that startups and shutdowns are normal operations. It is clearly impossible for those two sets of CO data to represent the myriad of types of sources and operating conditions subject to this regulation. Furthermore, even those two data sets do not show compliance with the CO limit at all times and, based on the firing information, they do not

include any significant startup and shutdown operations and only one of the two includes any turndown operations [Footnote: With respect to the gas-fired boilers for which EPA collected CO CEMS data, no data were collected while these units were operating at low loads. The data for the CATesoro boiler was from 71 to 81 MM Btu/hr. Assuming the upper value representing near design load, this variation is only 88 to 100%, not representative of the full operating range for most gas boilers. The other gas fired boiler, WABOEINGRENTON, shows significant variation from 15 to 40 MMBtu/hr with CO peak at about 25 MMBtu/hr. It is also worth noting that the reported CO concentration from the WABOEINGRENTON testing is well above the level of 1 ppmv CO that EPA has proposed for Gas 2.] We discuss our review of those two data sets in Attachment D, but it is clear that they are not representative of the source category, of turndown operations, or of startup and shutdown emissions from even the two units monitored, much less startup and shut down of the myriad types of units in the source category.

Emissions resulting from pollutants contained in fuel (i.e., mercury and chlorine) are unlikely to be different during turndown, startup and shutdown periods, but a simple understanding of combustion suggests that particulate emissions are likely to be higher during poor combustion periods such as may occur during these times. The impact of startup and shutdown conditions on dioxin/furan emissions is unknown, but that provides little certainty for sources that will have to certify that they complied with the dioxin/furan limits during these periods. Since there is no significant averaging period provided for PM or dioxins/furans and no compliance monitoring is possible, there is no basis for a source to certify compliance during such periods. Even if there were a is significant averaging time, sources have no basis for certifying compliance since operating conditions, stack temperatures, firebox temperatures, air-to-fuel ratios and other significant parameters are significantly different during these periods than during normal operation. If ever there is a case to be made that the application of a system for measuring the effect of the control measure for enforcement purposes is not practicable (one of the CAA section 112(h) criteria) it is for PM and dioxin/furans during turndown, startup and shutdown operation. The case for not applying numerical emission limits to CO, the surrogate proposed for organic HAPs, during turndown, startup or shutdown is made later in section VI.C.

The Agency argues on page 32013 of the preamble that special consideration of startup and shutdown periods is not needed because startups and shutdowns are predictable and do not happen more than once per day. We are not sure why these factors matter. If emissions during startups and shutdowns are different than during normal operation, which they are, it doesn't matter that the startup or shutdown was predictable. The compliance average will still be impacted to the same extent. In general, startups often take more than a day to complete and most take a significant part of a day. The number of startups in a day does not matter, however. What matters is the level of emissions during the startup or shutdown and the duration of those emissions relative to the averaging time of the standard. Units with CO CEMS (units over 100 MMBTU/hr) have a 30 day averaging time under the proposal. It only takes 1 day at 30 ppm CO to exceed that standard and such days will be the rule rather than the exception during boiler and process heater startups. For units under 100 MMBTU/hr the CO averaging time is 12 hours (3 four hour performance test runs), though as mentioned previously such a test is not allowed to include startup and shutdown periods and for many reasons could not be used even if it were allowed. Thus, for CO for units under 100 MMBTU/hr, there is no compliance methodology specified or available for startup or shutdown periods and work practice requirements and the 112(h) criterion is certainly met for these units. For units over 100 MMBTU/hr, CO CEMS are specified, though measurement during startup and shutdown periods might be possible.

However, in order to have accurate measurements to show compliance with the specified CO limit for normal operation, the CO CEMS will have to be spanned to about 10 ppm and the high CO emissions that occur during turndown, startup and shutdown periods will be above the span of the instrument. All-in-all, it is clear that measuring CO for the purpose of demonstrating compliance during periods of significant turndown, startup or shutdown is not practical

Many startups and particularly initial startups, startups after any refractory work, and shutdowns involving special operations such as decoking or soot blowing are unlikely to be able to meet the CO limits, even with add-on controls. Good operating practices and manufacturers recommendations require equipment to be gradually warmed-up to operating temperature in order to prevent thermal damage to mechanical components. Equipment manufacturers often specify heat-up rates and require conformance with these rates for equipment warranty. In order to provide for proper dry-out of refractory and to avoid damage to the refractory, initial and-post refractory work startups must be done even more slowly than normal startups. These types of operations often take more than a day, as the firebox temperature must be raised at a slow and controlled rate to prevent damage to the new or repaired refractory. During periods of low rate and low temperature operation, CO emissions will be high.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 89

Comment: Even for boilers and process heaters with extensive controls, the controls will be ineffective during startup and shutdown period and possibly during turndown periods. For instance;

* Oxidation catalyst is ineffective at reducing CO or dioxin/furans during such operations due to low stack temperatures.

* A fabric filter (FF) cannot be put into service until the flue gas temperature is above the dew point. This requires that all heat transfer surfaces, ducts and flues from the combustion zone to the FF inlet be warmed up from ambient temperatures to dew point temperature (which varies by fuel type and fuel constituents, but is typically in excess of 140 degree F). It takes a considerable amount of time, typically several hours for larger units, to warm up this considerable mass of steel: waterwall tubes, superheater tubes, reheater tubes, economizer tubes, casings, turning vanes, air preheaters, ducts and inlet plenums. During this warm-up period, the FF cannot be put into service without risking catastrophic failure of the bags and intensive corrosion damage to the FF.

* Electrostatic precipitators (ESPs) must typically warm-up to be effective. Premature starting of this equipment will lead to short term stability problems that could result in unsafe actions and longer term degradation of ESP performance due to fouling, increased chances of wire damage or increased corrosion within the chambers.

* Units equipped with spray dryer absorbers (SDA) for acid gas removal are limited in the amount of reagent slurry that can be injected into the flue gas during startup. The slurry federate is limited due to the nature of the technology by the amount of moisture the flue gas can evaporate. This in turn requires that a minimum temperature be achieved by the flue gas before the slurry federate can be initiated, and imposes a lengthy period of time during which the slurry federate is significantly limited until all the upstream heat transfer surface and ductwork has been warmed up. As such, SDA cannot remove hydrogen chloride in significant quantities for several hours after the unit is first fired.

Comment: If CO levels average 30 ppm for even one day during a turndown, start-up or shutdown, the 30 day average will be exceeded for the subsequent 30 days that include the 30 ppm day. Thirty- day averages have been used in several rulemakings to address combustion emission variability. However, in essentially all of these rulemakings, turndown, startup and shutdown periods have been excluded from those 30-day averages. Arbitrarily including them in this proposal doesn‘t address their impact. Extending the averaging period to a 365-day average would help address the impact of incorporating these periods into the compliance averages, but such a long averaging period introduces other concerns and, as we discussed, measurements during these periods are generally infeasible in any case. Thus, addressing turndown, startup and shutdown through the 112(h) provisions makes the most sense.

Comment: For pollutants other than CO, there is less information on how their controls behave during turndown, start-up and shutdown, but, since those are inherently periods of poor combustion and unstable operation, we would expect there to be exceedances. For instance, the temperature of the stack gas going into the activated carbon absorption system will vary from ideal during startup and shutdown operations thus, mercury and dioxin removal will be less efficient than during normal operations.

We note that this issue is recognized in many permits and regulations. For instance, one member site reports that their permit allows 36 hours for refractory curing and 12 hours for normal startups and shutdowns as long as firing stays under 75% of design. During this time, NOx and CO concentration limits do not apply, but max lb/hr and T/yr limits still apply. Other special situations, where permits and/or regulations allow exceptions from certain limits include maintenance outages of forced air and air preheat systems. For instance, the Texas NOx RACT rule recognizes NOx limits will not be met during low firing rates and the Part 60 combustion rules (NSPS subpart D rules) exclude startup and shutdown from compliance averages for NOx.

Since it is not feasible for boilers or process heaters to meet all of the emission limits during turndown or certain startups and shutdowns, work practice requirements should be specified for these startups as provided for in 112(h). We recommend a startup and shutdown plan work practice along the lines of the Part 63 SS&M plan, for startups and shutdowns, and that turndown operations be addressed as they are in the GACT proposal, by not including such periods in the compliance averages.

Comment Excerpt Number: 92

Comment: Applying the emission limits during startups will encourage sources to try to shorten the startup period. Reductions in the amount of time required to warm the boiler or process heater up could be realized by increasing the ramp-rate of adding fuel to the unit. In theory, a boiler or process heater could be brought from first flame to full load in a matter of minutes, but decreasing the warm-up period from what the manufacturer‘s recommendations risks severe metallurgical and refractory stresses due to rapid changes in temperature and wide variances in temperatures across the unit and duct parts. Immediate failures could occur if inconsistent heating caused tears or ruptures in support steel or heat transfer surfaces, posing considerable risk to personnel in the plant. Failure rates would also increase due to the considerable stresses introduced by rapid heating and cooling cycles, yielding failures at unpredictable times (steady state operation or future startups or shutdowns). For this reason, OEM recommendations for startup times are closely followed across industry.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 93

Comment: A work practices approach for these periods also would be consistent with EPA's recently promulgated MACT standards for compression ignition reciprocating internal combustion engines (CI-RICE) [Footnote: 75 FR 9648 (Mar. 3, 2010)]. Based on comments received from stakeholders, EPA finalized work practice standards for startup because the agency determined that it was "not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations." [Footnote: 75 FR 9648 (Mar. 3, 2010) at 9656.] According to EPA, applicable test methods that would be needed to measure during these events "do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods." [Footnote: 75 FR 9648 (Mar. 3, 2010) at 9665.] Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. [Footnote: 75 FR 9648 (Mar. 3, 2010) at 9665.] Startup and shutdown periods for boilers encounter similar testing challenges and costs.

Recommendation: Provide work practice requirements for start-up and shutdown situations where emission limits cannot be met and exclude CO CEMS measurements during periods of turndown from compliance averages.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Robert D. Bessette

Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 105

Comment: Opacity limit of 10% on a daily block average will not be adequate to allow operation during SSM periods.
As recommended elsewhere in these comments, CIBO recommends that startup and shutdown periods be handled using a work practice standard. Limiting opacity to 10% on a daily block average may be appropriate for normal operation, but it will not allow startup and shutdown operations to proceed, since there is simply not enough time to average out to such a low limit.

Use of startup and shutdown work practice with a prescribed plan is an appropriate approach that can be tailored to the specific unit. A similar approach needs to be provided for malfunctions so that actions can proceed in an orderly and safe manner to address malfunctions.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 124

Comment: a. SSM periods should be handled as awork practice
Even with use of a 30 day rolling average for PM CEMS, that is not adequate to cover SSM periods, and the emissions data used to establish the emission limits does not include SSM periods. CIBO recommends that SS and M periods be handled with a work practice approach.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 133

Comment: The Coen emissions guarantees are not valid below 25% load. This is due to the higher levels of excess air at low loads that result from the minimum airflow levels required by NFPA. In addition, Coen noted that CO emissions during a cold startup would be significant due to the reduced temperatures of the boiler heat recovery surfaces. Under these conditions, unburned fuel that comes into contact with the cold surfaces will smolder (instead of combusting completely), and will form significant amounts of CO. Coen noted that CO emissions during a cold startup could average several hundred ppm for the first hour or more. This is more than enough to cause the 30-day rolling average to exceed the proposed limit for all 30 days including that startup hour.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 137

Comment: CO will vary significantly, even for the best performing units, because of operating variability, startup and shutdown operation, turndown operation, and burner outages for tune-up inspections or maintenance, among other reasons. CO will typical spike to several hundred ppm as a result of these activities and adjustments will take some time. A 1 or 2 ppm emission limit provides little leeway for such normal variations, even with a 30 day averaging time. The following chart shows the hours of an elevated CO value can occur to cause a deviation. Given the difficulty in measuring CO in the low ppm range and the common occurrence of CO spikes, a 1 or 2 ppm limit will frequently be exceeded, simply because of measurement variability and the normal variability or startup, shutdown or turndown activity.
[See submittal for graph of allowable excursions for 1 ppm monthly average CO]

Recommendation: Address normal CO operating and measurement variability in establishing any low ppm CO emission limit.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 178

Comment: Start-up, Shut-down, Malfunction
EPA is proposing that the emissions standards it has established in this rule apply during both normal operations and periods of startup, shutdown and malfunction (SSM). CIBO strongly disagrees with this approach, believing it is inappropriate to require compliance with emissions standards that are achievable during periods of steady-state operation during periods of startup and shutdown. CIBO also believes that affected sources may be unable to comply with the standards during SSM periods, and therefore the proposed standards are contrary to the CAA’s requirement that standards established under Section 112(d) be "achievable." See 42 U.S.C. § 7412(d)(2). According to the D.C. Circuit, this when "achievable" means "under the most adverse conditions which can reasonably be expected to recur." National Lime Ass’n v. EPA, 627 F.2d 416 (D.C. Cir. 1980). If sources cannot meet the proposed emissions standards during "routine" periods of startup and shutdown, nor during adverse periods of malfunction, the proposed standards are therefore not "achievable," and thus not compliant with the Act.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 179

Comment: A. EPA Asserts without Support that CEMs Data includes SSM Periods.
To support its conclusion that the proposed emission standards are achievable during all operational periods, including during SSM events, EPA asserts that startup and shutdown emissions replicate normal operation emissions. These conclusions are not supported by the record. EPA relied on continuous emission monitoring (CEMs) data obtained from best performing units, which EPA claims included periods of startup and shutdown. It is unclear to CIBO whether this CEMs data actually warrants these conclusions. First, it does not appear that any of the units considered in the data collection were in startup or shutdown during the 30-day period of testing that EPA looked at. If that is the case, then the CEMs data gives no bearing on whether units can satisfy emissions limits over a 30-day period if all startup and shutdown events are included.

Additionally, EPA is operating on the assumption that "[b]oilers, especially solid fuel fired boilers, do not normally start up and shutdown more than once per day[,]" and that "startup and shutdown are part of [boilers'] routine operations and, therefore, are already addressed by the standards." 75 FR at 32,012. These are not accurate conclusions for many boilers, as circumstances may necessitate multiple startups and shutdowns throughout a day, and additionally, that a boiler may routinely need to start up and shut down does not mean the emissions from those events are the same as the emissions during steady-state operation. Further, the CAA has been interpreted to require that emissions standards be achievable under the most adverse conditions that can be expected to occur, not under assumptions of what is normally done or not done. EPA has not show that it actually considered startup and shutdown periods even though it is proposing to implement emissions standards that should apply to units during steady-state operations as well as such periods.

Another concern that CIBO has is that EPA used 3-run stack test data, and not 30-day data, to set the proposed emissions floors. EPA uses test run data collected through the ICR phase II testing process – which reflect normal, often steady state, operating conditions – to set proposed floors. Even EPA's docket materials in support of the Proposed Rule acknowledge that this data fails to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Further, this data does not make use of the CEMs data (with the startup and shutdown information) in its variability analysis, which is where it would be the most helpful in reflecting real-world fluctuations in emissions.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Requiring Emissions Controls during SSM is Not Technically Feasible.
The current decision by EPA to 'eliminate' omission of startup, shutdown, and malfunction emissions records is not only 'short sighted' but technically unjustified. A series of previous emission control programs over the last twenty-five years has resulted in the installation of several 'systems' to achieve specific emission reductions through targeted technologies, but most are designed for 'steady state' or 'normal operations'.

The first of these was implemented under the CAA revision of 1990 that required units larger than 25 MWe to reduce sulfur emissions below 1.2 lb/MMBtu and achieve at least a 90% reduction. One of the few methods of doing this that could survive severe abrasive characteristics present in some units was dry limestone injection. This process is dependent on injection of 'sized' limestone into the furnace/boiler, calcinations of the limestone, and subsequent absorption of sulfur present in the flue gas. This process 'begins to occur' at a useful rate at about 860 deg. F and is 'functional' up to about 2200 deg. F. (Unfortunately at about 1640 deg. F thermal NOx generation normally inhibits operation above that temperature.) For a boiler to achieve the lower useful temperature of 860 deg. F, it must be 'heated up' to that level, generally using natural gas or fuel oil. This 'thermal change' to the materials that boilers are fabricated with, is limited by impacts of thermal stresses placed on both the generating tubes and drum materials, by the manufacturers to a change rate of 100 deg. F. Thus, to take a unit from 'cold' to the functional temperature that limestone becomes effective for SO2 removal, takes a minimum of about eight to ten hours. Application of 'normal steady state' limits based on a temperature of 1600 deg. makes no sense. Due to the high volume of combustion air involved, most 'casualties result in the unit falling outside of the optimum band for absorption also, so application of the limits during these periods is short sighted, as it is technically unfeasible to attain them.

A similar situation exists with respect to NOx. Many facilities were 'swept' into further NOx reduction under the 'NOx Budget Program' in the late 1990's. To meet these requirements, most installed a Selective Non-Catalytic Removal system, which injects ammonia or urea into the combustion gas stream and results in much of the NOx present there becoming a 'solid' and mixing into the ash residue from combustion. This process occurs at a meaningful level at temperatures above 1200 deg. F up to about 1650 deg. F. The same 'heat-up' limits apply for cold plant startup, as well as casualty impact as listed above.

A second '1990' requirement resulted in baghouse installation instead of electrostatic precipitators for any new installations. Unfortunately, for many of these units the baghouses were unable to withstand the 'gas stream temperature' when they were heated up to operating temperature with gas or fuel oil burners, as the 'bags' in them were limited to temperatures less than 350 deg. F. but greater than 150 deg. to avoid water formation/plugs in the ash and air stream. The high end could not be maintained with limited combustion air heater flow until the units temperature approached about 800 deg. F during the heat up, while the lower end was present until achieving at least 300 deg. during the heat up. A ‘baghouse’ bypass was installed for that purpose, although not used at any other time. Currently ‘some’ bag vendors have developed replacements that can withstand a higher temperature and are more resistant to casualty situations, but not all of them.

All of the above are functional in reverse during a shutdown. Other types of ‘emissions removal’ (e.g., SCR) also require specific ‘thermal inlet’ temperatures to function that cannot be maintained during either startup, shutdown, or during specific malfunctions.

Lastly, many CEM units are ‘calibrated’ to operate at specific stack temperatures associated with ‘normal operations’. During ‘thermal cycles’ of the unit, it is doubtful that any of the CEMs maintain required accuracy much less record actual ‘emissions.’ It is likely that the only trustworthy data is opacity during SSM as most of the other instruments may provide an output, but nothing in the current regimen of testing assures its accuracy.

EPA has long recognized that control and/or monitoring equipment is not necessarily functional during SSM periods. In developing the SSM approach in the General Provisions, EPA recognized the "difficulty of determining compliance" during SSM periods. 58 FR 42,777 (Aug. 11, 1993). EPA adopted an approach whereby an owner of an affected facility who abides by a valid SSM plan during SSM periods would not be deemed in violation of the applicable standard. EPA stated:

This approach carries forward the requirement that control systems be operated at all times, but it allows special situations to occur, such as unpredicted and reasonably unavoidable failures of air pollution control systems, when it is technically impossible to properly operate these systems. 58 FR 42,777 (Aug. 11, 1993).

In the preamble to the final General Provisions, EPA responded to one commenter who said EPA should require affected sources to meet otherwise applicable emission limits during startups, shutdowns, and malfunctions. EPA said it "believes, as it did at proposal, that the requirement for a startup, shutdown, and malfunction plan is a reasonable bridge between the difficulty associated with determining compliance with an emission standard during these events and a blanket exemption from emission limits." 59 FR 12,423 (Mar. 16, 1994). We believe EPA’s rationale applies to affected sources subject to the Boiler MACT standards and we fully support retaining this approach to startup, shutdown and malfunction in the final regulations.

Response: See the preamble for achievability of limits, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: C. An Extended Averaging Period Will Not Eliminate Problems With Making Emissions Limits Applicable During Startup and Shutdown Periods.
Institutional, commercial and industrial boilers, require an extended period of startup lasting several hours (e.g. gas, liquid, or solid fuel boilers) or days (e.g. large circulating fluidized bed boilers). During the required startup periods, most, if not all, equipment in the boiler and pollution control systems are not operating in their normal condition. Consequently, pollutant emission concentrations and emission rates can exceed those experienced during normal operation. It is very common in the boiler industry for certain control devices to be out of operation during periods of startup due to the nature of the equipment. During such periods it is likely that emissions will exceed the standards proposed and would never be able to recover to meet the average limitations. (See below for a more expanded discussion with respect to a few specific technologies). This extended startup period, ranging from several hours to a few days for some specific units, is required due to equipment integrity concerns, limitations of the technologies, or safety concerns:

Equipment Integrity – For example, a Fabric Filter (FF) cannot be put into service until the flue gas temperature is above the dewpoint. This requires that all heat transfer surfaces, ducts and flues from the combustion zone to the FF inlet be warmed up from ambient temperatures to dewpoint temperature (which varies by fuel type and fuel constituents, but is typically in excess of 140°F /60°C). It takes a considerable amount of time, typically several hours for larger units, to warm up this considerable mass of steel: waterwall tubes, superheater tubes, reheater tubes, economizer tubes, casings, turning vanes, air preheaters, ducts and inlet plenums. During this warmup period, the FF cannot be put into service without risking catastrophic failure of the bags and intensive corrosion damage to the FF. This limits a unit's ability to control Particulate Matter and Mercury during the several hours of startup.

Limitations of the Technology – For example, units equipped with a Spray Dryer Absorber (SDA) for acid gas removal are limited in the amount of reagent slurry that can be injected into the flue gas during startup. The slurry federate is limited due to the nature of the technology by the amount of moisture the flue gas can evaporate. This in turn requires that a minimum temperature be achieved by the flue gas before the slurry federate can be initiated, and imposes a lengthy period of time during which the slurry federate is significantly limited until all the upstream heat transfer surface and ductwork has been warmed up. As such, SDA cannot remove Hydrogen Chloride in significant quantities for several hours after the unit is first fired.

Safety Concerns – For example, reductions in the amount of time required to warm the boiler system up could be realized by increasing the ramp-rate of adding fuel to the unit. In theory, a boiler could be brought from first flame to full load in a matter of minutes, but decreasing the warm-up period from what the OEM recommends risks severe metallurgical stresses due to rapid changes in temperature and wide variances in temperatures across boiler and duct parts. Immediate failures could occur if inconsistent heating caused tears or ruptures in support steel or heat transfer surfaces, posing considerable risk to personnel in the plant. Failure rates would also increase due to the considerable stresses introduced by rapid heating and cooling cycles, yielding failures at unpredictable times (steady state operation or future startups or shutdowns). For this reason, OEM recommendations for startup times are closely followed across industry.

Comment: EPA makes a mistaken assumption that startups and shutdowns are "predictable and routine." 75 FR at 32,012. Industrial facilities, unlike electric utilities, typically operate a large number of smaller units of varying ages instead of operating a small number of very large units. When normal equipment failure rates (e.g., tube leaks) are multiplied across a large number of units, the total number of unit failures can be significantly larger at industrial facilities. One member company operates a facility with over a dozen boilers, which average more than two unplanned outages per unit above and beyond each unit’s planned outage in a any given year. It is not uncommon for unplanned outages to occur in clusters, such as when a given component (e.g., an economizer) might suffer a failure due to corrosion or erosion. Repairs may fix the failure at identified vulnerable areas nearby, but the root cause of the failure could be occurring in multiple areas that are not easily identified, resulting in additional failures in a short timeframe.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 183

Comment: EPA seeks to address the fact that units will not be able to comply with the proposed emissions standards by during startups and shutdowns by proposing extended (daily or monthly) averaging periods. The assumption that longer averaging periods will provide a reasonable method to ensure compliance is likewise flawed. Startup and shutdown periods vary in duration and intensity, a fact that can significantly impact actual emission profiles. Additionally, because unplanned outages are a reality in the operation of any boiler, industrial or utility, and because unplanned outages are by their nature unpredictable, unplanned shutdowns can and will cluster together. For example as shown by the table (see submitted for example emission data), if a unit firing eastern bituminous coal equipped with a Spray Dryer Absorber for acid gas control were to have two unplanned outages in the month following startup from a planned shutdown, the calculation of a 30-day average fails to prevent a deviation from the HCl standard:

Such a scenario would result in a unit being out of compliance because EPA inappropriately failed to craft a compliance protocol to address the fact that emissions performance during startups and shutdowns is necessarily not equivalent to emissions performance during steady-state operation.

Extended averaging periods are similarly inadequate to provide a reasonable method to demonstrate compliance with the CO standard, due to the inherent variability of CO in solid fuel boilers across the load range, but especially upon startup. See the figure below showing CO data from a coal stoker fired boiler that monitors CO via CEMS. It is readily apparent that CO emissions during normal startup conditions can be two orders of magnitude above the proposed standard of 50 ppm for stoker boilers. (See submittal for coal stoker fired boiler carbon monoxide during startup figure.)

This table (see submittal for table of CO emissions) demonstrates the impact of the startup of this unit on the calculation of a 30-day average.

This data set illustrates the impact of a typical unit startup on a calculated 30 day average and the problem with requiring a unit to comply with a steady-state emission standard during startups and shutdowns. Had this unit been subject to the standard proposed in this rule, the source would have been out of compliance due to the two calendar days that saw startup activities, despite the fact that the source was operated near or below the proposed standard for CO the following 40 days.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 184

Comment: Instead of relying on extended averaging periods, EPA should instead provide additional provisions to ensure emissions are minimized during startups and shutdowns without unreasonably requiring sources to attempt to comply with steady-state emission standards. EPA should add provisions to require sources to develop and adhere to operating practices specific to the unit's design, fuel type, and OEM recommendations that will ensure emissions minimization without forcing owner/operators to choose between putting their equipment integrity and personnel safety at risk versus failing to comply with this rule. Such an operating practice should be crafted to be flexible, given the wide variety of boiler sizes, types, vintages, and fuels fired, and should be developed by the source based on OEM recommendations. General guidelines could include:

* Sequencing of equipment startups, per OEM recommendations;
* Startup time durations, per OEM recommendations, and
* Provisions to clearly define what constitutes "online" versus "startup". This could be crafted to mean a percentage of the unit's maximum continuous rating, or steam temperature/pressure, etc.

CIBO notes that EPA followed this approach in its final rule for Reciprocating Internal Combustion Engines (RICE) issued on March 3, 2010. There, EPA concluded "it was not feasible to prescribe a numerical emission standard for stationary CI engines during periods of startup because the application of measurement methodology to these engines is not practicable due to the technological and economic limitations described below." 75 FR 9665. Many of the reasons EPA articulates for this decision apply to the boiler and process heater source category regarding the accuracy of the stack gas sampling methods during transient load cases like startup. Eastman recognizes that EPA has set work practice standards in the RICE rule by limiting startups to 30 minutes. We agree this is appropriate. However, when it comes to boilers and process heaters, it is a much more complicated issue. Given the variety of units, operating pressures and temperatures, etc., we do not believe it is practical to set startup and shutdown periods on a "one-size fits all" basis. Rather, each source should work with their permitting authority to establish and obtain approval of appropriate work practice standards as we discuss above.

CIBO proposes two solutions to fix the deficiencies in the Proposed Rule relative to startup/shutdown emissions expectations. First, CIBO proposes that EPA should use operating practices during startup and shutdown to include general content relative to specific startup and shutdown sequences and time limits pending meeting emissions limits. Alternatively, if EPA uses a startup/shutdown standard, EPA should establish an averaging period that accounts for a wide range of emissions from startup and shutdown.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 185

Comment: d. Malfunction Periods Not Account for in Floor Setting.
The Proposed Rule also expects that the emissions standards applicable during normal operations must also be met during periods of malfunction. This expectation directly conflicts with the statutory requirement that EPA set MACT standards that are "achievable" since even the best performers will experience malfunctions that may result in those sources not meeting the proposed standards. CIBO is also concerned that compliance with the emissions standards during

malfunction events will be difficult to gauge since emissions testing during such events is near impossible given the sporadic and unpredictable nature of malfunctions.

Another concern is that the Proposed Rule could force units to choose between safety and compliance with emissions requirements. For some affected units, malfunctions by their very nature create unsafe conditions which can lead to excessive combustible mixtures in a furnace that can result in explosions, equipment damage and personnel hazards.

Response: See the preamble changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 186

Comment: CIBO proposes that EPA set work practice requirements based on maintenance plans established by each source. Such plans should be expected to address how to expeditiously deal with malfunctions in a way that balances the desire to most efficiently minimize emissions while also maximizing safety responses and expeditiously resolving malfunction events. While the Sierra Club court ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under Section 112. See Sierra Club v. EPA, 551 F.3d at 1028. In such limited circumstances, section 112(h) "work practices" or "operational" standards are available. Id.

Section 112(h) allows the Administrator to promulgate a design, equipment, work practice, or operational standard, or combination thereof, in lieu of an emission standard where it is not feasible to prescribe or enforce an emission standard. 42 U.S.C. § 7412(h). Infeasibility exists where "a hazardous air pollutant or pollutants cannot be emitted through a conveyance designed and constructed to emit or capture such pollutant,’ or "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Id. Because of the difficulty of obtaining emissions data during malfunction periods, and the substantial variety of circumstances that may manifest during malfunction events, it would be difficult and impractical and infeasible for EPA to craft emissions standards for application during both malfunction periods and normal operations. Thus, CIBO believes that the best approach is not to continue with the present proposal of applying the same standards EPA has set for normal operations to malfunction events, but rather, for EPA to use § 112(h) to set work practice standards that would allow facilities to establish source-appropriate procedures during malfunctions. Such procedures would enable sources to maintain safe practices while addressing the malfunction and implementing procedures to minimize emissions during any such event.

Comment Excerpt Number: 187

Comment: EPA states in the Proposed Rule that if a source fails to comply with the applicable standard due to a malfunction, EPA "would determine an appropriate response." 75 FR 32013. Many large sources have been required to submit "Standard Operation and Casualty Procedures" under Title V concerning time limitations of malfunctions that impact emissions. These procedures were based on not exceeding monthly averages in the permit. Furthermore, the definition for "malfunctions" appears to be inappropriate considering that many malfunctions occur due to component failure and have nothing to do with "poor maintenance or careless operation" as defined in 40 C.F.R. § 63.2. Congress acknowledged that malfunctions cannot be prevented, and provisions allow for such occurrences. [CITE] EPA also acknowledges that malfunctions cannot be prevented, even by top performers, and therefore defines the regulations at 40 C.F.R. at § 60.2. EPA unreasonably proposes all sources to comply with standards established for steady-state operation during periods of malfunction. This approach inappropriately fails to include provisions that take into account the unpredictable nature of malfunctions, and that malfunctions occur to all units including top performers.

EPA should include additional provisions to accommodate the unpredictable and unavoidable malfunctions that both Congress and EPA acknowledged would occur. EPA should adopt a work practice of requiring malfunction plans to address potential equipment failures, provide troubleshooting and corrective actions, and other reasonable measures so to minimize the duration of malfunctions and minimize emissions during unavoidable malfunctions. Using the plan and documenting actions in accordance with the plan would then constitute minimizing emissions via the general duty clause.

Document Control Number: EPA-HQ-OAR-2002-0058-2794.1
Comment Excerpt Number: 8

Comment: Contrary to statements in the preamble for the proposed standards, EPA does not appear to have considered data from start-ups and shutdowns in its floor analysis.

The proposed rule is deficient because it lacks specific start-up, shutdown, and malfunction emission standards or work practice standards for boilers, although the Agency argues that it considered SSM emissions in establishing the floors for the proposed standards. For instance, EPA insists that SSM events are included because the emission limits are based on continuous emission monitoring data:

"The standards that we are proposing are daily or monthly averages. Continuous emission monitoring data obtained from best performing units and used in establishing the standards, include periods of startup and shutdown. Boilers, especially solid fuel fired boilers, do not normally startup and shutdown more than once per day. Thus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards."

at 32,012-13. In this discussion, EPA also asserts that startup and shutdown are part of “routine operations” and are therefore “already addressed” in the MACT standards. EPA’s docket materials do not support these statements.

In establishing proposed MACT limits, EPA clearly did not rely on the CEMs data when setting the floors for boilers and process heaters. To the contrary, as indicated by the MACT floor memo, EPA uses test run data collected through the ICR phase II testing process, which reflect normal (often steady state) operating conditions, to set the proposed floors. Thus, according to EPA’s own docket materials, the data used to set the proposed floors fail to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Furthermore, as the MACT floor memo makes abundantly clear, EPA’s approach does not make use of the CEMs data (with the startup and shutdown data) in its variability analysis where it would be the most helpful in reflecting real world fluctuations in emissions.

Response: See the preamble for discussion of MACT floor methodologies, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: H. Allen Faulkner
Commenter Affiliation: Ascend Performance Materials, LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2743.1
Comment Excerpt Number: 1

Comment: Ascend operates three coal fired boilers at its Decatur site that will be required to meet the emission limits set forth in the Boiler MACT rule. The site uses electrostatic precipitators (ESP) for particulate matter (PM) emission control on all of the units. During normal startups of these units, the ESP cannot be initiated until that unit reaches a specified operating temperature, per its design parameters. As a result, it takes, typically 4 hours, from initial startup of a coal fired unit to the startup of pollution control equipment, which means that the emission limit cannot be met on the unit, even with time weighted averaging of the emissions. Ascend requests that EPA consider an alternative approach for the startup and shutdown emission limits, such as work practice standards.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Dale A. Riddle
Commenter Affiliation: Seneca Sustainable Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2866.1
Comment Excerpt Number: 2

Comment: During the shutdown process and subsequent startup (six to eight hours), it may be impossible to meet the literal CO limits contained in the proposed rules.

In order to safely start up a biomass boiler without risk of causing explosion and avoid undue stress to the boiler, it is necessary to heat up the boiler slowly and without the benefit of particulate controls. EPA has recognized that until combustion is stable and the boiler has reached an exhaust temperature of 250F, it is not safe to energize an ESP. This fact has been recognized in prior rules such as the Boiler NSPS. In the proposed rule, EPA grants no recognition of the realities of biomass boiler startups, imposing the standards applicable to normal operation to days where startups occur. The only recognition of the anomalous conditions that exist during startup was to state that 24-hour averaging would enable boiler operators to demonstrate compliance notwithstanding startup. This is grossly inaccurate. Startups can routinely take six to eight hours and opacity readings (although not necessarily accurate as recorded by a continuous opacity meter), can reach 90 percent. It is well known that initial opacity readings do not reflect actual opacity as considerable moisture is driven off the kindling fuel and the interior surfaces of the boiler resulting in water vapor that is inaccurately read as opacity. However, there is also significant opacity during startup that is not capable of being reduced as the control equipment cannot be energized until the moisture is driven off and the interior surfaces adequately warmed up. Rushing this process can result in damage to control equipment and explosion concerns. As a result, notwithstanding good operation, it is probably mathematically impossible to average the startup opacity conditions with the opacity once normal operations have commenced to comply with a 10 percent opacity standard applicable to those biomass boilers employing ESPs or scrubbers (the vast majority of the controlled boilers in this subcategory).

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Jeffrey R.Klieve
Commenter Affiliation: Monsanto Company
Document Control Number: EPA-HQ-OAR-2002-0058-2754.1
Comment Excerpt Number: 2

Comment: Table 2 of the proposed rule lists the CO emission limitations for Gas 2 boilers and process heaters at 1 ppmv dry basis corrected to 3% 02 on a 30-day rolling average for units 100 MMBtu/hr or greater; 3-run average for units less than 100 MMBtu/hr. However, USEP A has not established different emission limitations for periods of boiler startups, shutdowns and malfunctions, stating that emissions during these events are taken into consideration in the averaging times of the proposed standards. Monsanto operates a gas-fired boiler with a CO CEMS and the unit generally operates below the proposed 1 ppm standard. In review of historical CO CEMS data during typical startups and shutdowns for this boiler, we found that the 30-day rolling average may exceed the proposed standard by as much as 70%. Startup times would be longer during cold startups or when repairs have been completed, such as replacement of refractories in the boiler. Therefore, the proposed concentration level combined with the long averaging time for the CO standard is not adequate to cover startup and shutdown events, either planned or unplanned.

This approach is inconsistent with the General NESHAP Provisions found at 40 CFR 63.6(e):

... The general duty to minimize emissions during a period of startup, shutdown, or malfunction does not require the owner or operator to achieve emission levels that would be required by the applicable standard at other times if this is not consistent with safety and good air pollution control practices …

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Jeffrey R.Klieve
Commenter Affiliation: Monsanto Company
Document Control Number: EPA-HQ-OAR-2002-0058-2754.1
Comment Excerpt Number: 3

Comment: Monsanto is also concerned that a concentration-based standard during startup and shutdown periods does not appear to be valid. Since the firing rate during these periods is much lower than typical values, the actual mass flow of CO emitted at a specific CO concentration is also much lower than during typical operating periods. In other words, the actual CO emissions can very well be lower during these periods, but the rule as proposed, would not take this into account.

Accordingly, Monsanto requests that USEPA revisit this treatment of SSM events and either treat them in a manner consistent with 40 CFR 63(e), or provide a higher limit for certain pollutants during such events.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Michael J. Nasi
Commenter Affiliation: Gulf Coast Lignite Coalition
Document Control Number: EPA-HQ-OAR-2002-0058-2800.1
Comment Excerpt Number: 3

Comment: EPA’ s inclusion of startup shutdown emissions in the emission standards creates unattainable and inflexible standards in conflict with prior guidance.

In 2008, the U.S. Court of Appeals for the D.C. Circuit vacated the EPA's exemption from CAA Section 112 requirements for 'Hazardous Air Pollutant (HAP) emissions during periods or startup, shutdown, and malfunction (SSM). [Footnote: Sierra Club v. EPA, 551 F.3d 1019 (DC Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265 (2010).] In light of the decision, EPA issued guidance in 2000 addressing SSM emissions for a variety of sources, recognizing that emission standards under (Clean Air Act Section 112(d) should be attainable as they are expressed as an average over a relatively long period of time (e.g., yearly). [Footnote: 75 FR at 32025 (June 2, 2010).] Also. the "EPA will give highest priority to reviewing, and revising those Section 112(d) source category standards that may be difficult for sources to meet during an SSM period given the technological limitations of the processes involved. [Footnote: See July 22, 2009 EPA letter Re: Vacatur of Startup, Shutdown, and Malfunction Exemption, available at <http://www.epa.gov/oecaerth/civil/caa/ssm-memo080409.pdf>.]

The EPA must not deviate from the guidance language since the vacatur of the SSM exemption. Where before emission standards averaged over a year were viewed as attainable, here the EPA is stating that the proposed emission standards averaged over a day or month are attainable. [Footnote: 75 Fed.Reg. at 32013.] Further. EPA previously recognized in the guidance letter that sources will require some flexibility due to technological limitations. The industrial Boiler NESHAP preamble does not afford the same recognition of for technological limitations. [Footnote: 75 Fed.Reg. at 32012. "[EPA is] not establishing a separate emission standard for these periods because startup and shutdown are part of their routine operations and , therefore, are already addressed by the standards.] EPA creates a discrepancy in the application of the NESHAP based on fuel choice by requiring emission standards tilt some boilers, which include highly variable emissions during startup and shutdown periods averaged over a fairly short time period.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Dale A. Riddle
Commenter Affiliation: Seneca Sustainable Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2866.1
Comment Excerpt Number: 3

Comment: We strongly encourage EPA to develop an exception to compliance with the work practice standards. Other recently promulgated NESHAPs have recognized that it is impossible to demonstrate compliance with emission standards during startup conditions and have allowed sources a reasonable period where they do not need to demonstrate compliance with the limits. For example, the Subpart ZZZZ NESHAP allows natural gas and diesel-fired engines a startup period during which the standards do not apply. If this can be allowed for fossil-fuel-fired units such as reciprocating internal combustion engines, a similar approach should be recognized for biomass boilers. Therefore, we recommend that EPA revise the rules to allow an eight-hour startup period during which the limits do not apply. Because this time may not be adequate for startup of some larger boilers without any supplementary fuel capability, we also suggest that EPA clarify that sources can apply to EPA for a longer startup time period.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 3

Comment: Duke Energy urges EPA to use its authority under the CAA Sections 112 (d) (h) and 111 to provide a work practice operational standard to address HAP emissions during startup and shutdown in lieu of a numerical limit.
HAP emissions during startup and shutdown ("SU/SD") should not be treated the same as HAP emissions during normal operations. EPA has not established a basis to conclude that SU/SD emissions of HAP are the same as during normal operations. Setting the same standard for SU/SD and normal operations will result in an unattainable standard for the owner/operator despite the application of MACT controls. In setting MACT standards, EPA must properly characterize the entire range of operation of the units used to determine the MACT Floor. EPA has to do this so that the units that set the MACT floor limits can actually comply with those limits. In its industrial boiler information collection request ("ICR"), EPA did not require any testing during start-up and shutdown events. However it is well documented that emissions profiles during these periods are significantly different from those during normal operation. SU/SD periods have highly variable operating conditions and consequently, reference test methods cannot be utilized because the sources do not operate in a steady state as required by the methods. As such, EPA biased the ICR testing by only specifying that tests be conducted at full load operation, and missed the extended start-up periods that electrostatic precipitators ("ESP"), selective catalytic reduction ("SCR"), and some flue gas desulfurization ("FGD") control systems require to achieve optimal performance. Without emissions data during these periods, EPA has no data and no factual basis for concluding that the best performing units can achieve the proposed MACT limits during start-up and shutdown events.
There are inherent problems in setting SU/SDS standards the same as the standards for normal operation, particularly for any standard that is based on an averaging time that is shorter than 30 days or based on a few isolated short-term performance tests. Control devices and mechanisms do not perform at the same level of efficiency during these transitional periods when suitable and stable temperatures or chemical conditions have not been achieved. Certain plant components must be started in a specific sequence in order to ensure that steady state operations can be achieved, and not all pieces of control equipment will be operating at peak efficiency during start-up and shutdown. For example, industrial boilers equipped with SCR, must achieve a minimum flue gas temperature of 535-600 F (depends upon SO_3 concentration) before reagent can be injected and react with the SCR catalyst. Flue gas temperatures must reach 270 F for cold-side ESPs and 600F for hot-side ESPs to effectively control particulate matter ("PM") and HAP associated with PM. A typical hot start-up takes 6-8 hours and a cold start-up may take 8- 24

hours. Industrial boilers equipped with FGDs that use "mag-enhanced lime" can require 24- 36 hours to build proper chemistry conditions for effective control as designed.

Setting standards for SU/SD the same as for normal operation for wood-fired biomass boilers is also problematic. At a recent pollution control user's group conference held in Charlotte NC, Duke Energy and others learned that boiler and pollution control vendors are also concerned with the SU/SD features of the proposed industrial boiler MACT standards. Vendors are unwilling to guarantee emission rates for PM and carbon monoxide ("CO") based on the

proposed ICI boiler MACT standards, and are particularly concerned with the numerical limits for SU/SD. As a consequence, several, untreated wood biomass projects have been postponed or cancelled due to the regulatory and compliance uncertainties of the proposed MACT standards, including the SU/SD provisions. There is no justification or technical basis for setting a numerical SU/SD limit with no data to support the limit. Setting numerical SU/SD limits without data based on an averaging period less than 30 days or based on a single or few isolated performance tests will result in an unattainable standard.

EPA should replace the numerical SU/SD limits with a work practice/operational standard that require owners/operators to maintain and operate the industrial boiler in a manner consistent with good engineering and air pollution control practices as EPA did for the stationary RICE engine MACT rule. Owners/operators could be required to maintain a SU/SD Plan on site that identifies good engineering and pollution control SU/SD practices and procedures that recognize specific boiler and pollution control equipment designs. This approach is justified under the CAA Section 112 (d) and (h), and is the only practical way to address HAP emissions during SU/SD given EPA's lack of any emissions data during these periods. EPA has not established a technical basis to conclude that SU/SD emissions of HAP are the same as during normal operations. The assignment of any SU/SD numerical limit, even based on a 30 day average, is arbitrary and capricious, and infeasible given the lack of test data. The extensive testing that would be required to establish SU/SD numerical limits is not feasible and impractical from a technical or economic perspective. Setting any numerical SU/SD limit would need to be delayed until the necessary testing is completed. Testing would have to be source-specific and based on several tests over an extended period of time to come close to being representative of variations in boiler SU/SD conditions, and specific boiler and pollution control equipment designs. One would expect results of CO, PM, and HAP test results to vary greatly from one test to the next during transition SU/SD periods. FGDs, ESPs, and SCRs do not function or function poorly during SU/SD transitions. Since pollution control equipment is not designed to control during this transition, SU/SD testing would need to be done on essentially an uncontrolled boiler. Mandatory use of control equipment prematurely for the tests could damage or shorten the life of the pollution control equipment (or catalyst) and create unintended operational issues.

Emissions from industrial boilers are different during normal operation and transition periods of SU/SD and it is not feasible to establish numerical emission standards. This situation

is the circumstance in which Congress envisioned a work practice standard for periods of startup, shutdown and malfunction in 112 (h) of the CAA, and they reserved the application of numerical limits for normal operations. Setting MACT standards for normal operation based on suitable data and establishing a work practice/operation standard(s) for SU/SD that recognizes specific boiler and pollution control system designs will result in a MACT standard that applies at all time and is consistent with the recent Court Decision (Sierra Club v. EPA, 551 F. 3d 1019).

Comment: EPA Should Allow for a Startup, Shutdown, and Malfunction Exemption. EPA failed to properly account for periods of startup, shutdowns, and malfunctions in developing the proposed MACT standards. Stack testing during the ICR was done with the units at normal operating loads thereby ensuring that none of the data collected was representative of these periods. Startups and shutdowns occur as a part of normal plant operations; however, the emission rates during these periods are not similar to those during steady-state operation. Unit processes may not operate at peak efficiency until the unit achieves a certain temperature (increase in products of incomplete combustion, control devices not operating properly) or process rate. The increase in actual emission rate would greatly skew the emission rate over the proposed averaging periods due to the scarcity with which AEP's units are operated. A consequence of this is to operate the boilers (normally used for EGU startup) for a greater period of time for emission rate averaging purposes.

Comment: The proposed rule states that startup, shutdown, and malfunction (SSM) events must be subject to the MACT floor. One particular example is coke oven gas (COG) furnaces at steel mills, which must shut down annually 28 days per year; a situation which leads to increased emissions.

USW believes it is essential that SSM data be included in the calculation of the MACT floor for all pollutants and all subcategories. The Union recommends that EPA gather SSM data for all pollutants and subcategories subject to the MACT floor.

Comment: Provide a Startup Exemption

The proposed rules provide no recognition of the elevated emissions levels associated with the startup of biomass boilers. In order to safely start up a biomass boiler without risk of causing explosion and avoid undue stress to the boiler, it is necessary to heat up the boiler slowly and without the benefit of particulate controls. EPA has recognized that until combustion is stable and the boiler has reached an exhaust temperature of 250F, it is not safe to energize an ESP. This fact has been recognized in prior rules such as the Boiler NSPS. In the proposed rule EPA grants no recognition of the realities of biomass boiler startups, imposing the standards applicable to normal operation to days where startups occur. The only recognition of the anomalous conditions that exist during startup was to state that 24 hours averaging would enable boiler operators to demonstrate compliance notwithstanding startup. This is grossly inaccurate. Startups can routinely take 6 to 8 hours and opacity, as recorded by a continuous opacity monitor, can reach 90 percent. It is known that not all of those readings accurately reflect opacity as considerable moisture is driven off the kindling fuel and the interior surfaces of the boiler, resulting in water vapor that is inaccurately read as opacity. However, there is also significant opacity during startup that is not capable of being reduced as the control equipment cannot be energized until the moisture is driven off and the interior surfaces adequately warmed up. Rushing this process can result in damage to control equipment and explosion concerns. As a result, notwithstanding good operation, it is mathematically impossible to average the startup opacity conditions with the opacity once normal operations have commenced to comply with a 10 percent opacity standard applicable to those biomass boilers employing ESPs or scrubbers (the vast majority of the controlled boilers in this subcategory).

We strongly encourage EPA to develop an exception to compliance with the work practice standards. Other recently promulgated NESHAPs have recognized that it is impossible to demonstrate compliance with emission standards during startup conditions and have allowed sources a reasonable period where they do not need to demonstrate compliance with the limits. For example, the Subpart ZZZZ NESHAP allows natural gas and diesel fired engines a 30 minute startup period during which the standards do not apply. If this can be allowed for fossil fuel fired units such as reciprocating internal combustion engines, a similar approach should be recognized for biomass boilers. Therefore, we recommend that EPA revise the rules to allow an 8 hour startup period during which the limits do not apply. Because this time may not be adequate for startup of some larger boilers without any supplementary fuel capability, we also suggest that EPA clarify that sources can apply to EPA for a longer startup time period.

Comment: Startup, Shutdown, Malfunction: The proposed standards do not adequately account for periods of startup, shutdown or malfunction because the EPA uses short-term performance test results to set emission limits, not the results of long-term Continuous Emission Monitoring. EPA must recognize that boilers do not run at a "steady state" condition; therefore the proposed limits cannot be met while boilers are starting up and shutting down.

Comment: Vendors question whether the CO standards are achievable during start up/shut down after CO and PM MACT controls are installed. Boiler vendors are unwilling to guarantee emission rates based

on the proposed ICI boiler MACT standards for PM and CO for new, reconstructed, and modified industrial boilers designed for wood biomass, particularly where the SU/SD standard is based on a daily averaging time or where performance testing includes SU/SD. Owners/operators of ICI boiler sources must have alternatives that provide a suitable chance for compliance during transitional SU/SD periods when their units are equipped with MACT controls.

Comment: It is common knowledge that high CO levels result from incomplete combustion; information which EPA and the courts can take notice. Moreover, EPA's own data on emissions during startups and shutdowns demonstrates that carbon monoxide levels are up to twenty times greater during such periods. Oxygen levels are higher, resulting in the corrected pollutant concentrations being much higher when fuel values are low, as during periods of start-up and shutdown. If EPA had examined these data in some detail, it would have recognized two important aspects of the startup and shutdown periods. First, during startup periods, the oxygen content of the flue gas is generally very high, resulting in high calculated concentrations of pollutants, when they are corrected to 3 or 7 percent oxygen. Second, during shutdown periods many types of boilers continue to emit pollutants for some time while the fuel feed rate has gone to zero. Thus, during those periods the pollutant emission rates when measured in terms of the heat input rate would contain a zero in the denominator and would equal infinity. Combining emissions during shutdown periods with all operating periods would mean an emission limit of infinity. Based on this ridiculous outcome, we recommend that EPA exclude periods of startup and shutdown from its numerical standards and replace them with work practice standards aimed at minimizing pollutant emissions.

Comment: Sierra Club v. EPA does not require EPA to establish standards that included SSM events.

EPA also asserts that "Consistent with Sierra Club v. EPA, EPA has established standards in this rule that apply at all times." 75 Fed. Reg. 32012 (emphasis added). But the court's 2008 decision does not require SSM events be part of a single standard that applies at all times. In Sierra Club

v. EPA, 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010), which vacated the "automatic" exemption in 40 C.F.R. § 63.6(f)(1) and (h)(1) for SSM periods, the D.C. Circuit ruled simply that sources cannot be exempt from complying with MACT standards. However, the court also noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112, and so section 112(h) "work practices" or "operational" standards may be available. Id. at 1028. Moreover, the same court also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing NSPS under section 111 of the CAA, Portland Cement Ass'n v. Ruckelshaus, 486 F.2d 375, 398 (D.C. Cir. 1973), the court acknowledged that "'startup? and „upset? conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." Id.
at 399. In sum, these opinions support separate provisions in a standard that address control of emissions during different operating modes, including start-ups and shutdowns.

Comment: Malfunctions, particularly, should be treated as a "distinct operating mode" and accordingly require a separate standards.

With regard to malfunctions, EPA argues in the preamble to the Proposed Boiler MACT that these periods should not be viewed as a "distinct operating mode," and thus, emissions from these periods do not need to be factored into developing the MACT floor levels. 75 Fed. Reg. 32013. Moreover, EPA states that even if malfunctions were to be considered a distinct operating mode, it would be "impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters" given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration. Id.

Considering that EPA's proposed MACT standards are supposed to apply at all times, the implication is that periods of malfunction also are covered by the same MACT standards that also apply during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable." EPA has failed to recognize that it is likely that even best performers will experience malfunctions and that is unreasonable. It is possible for pollution control equipment to fail in various ways. Electrostatic fields trip, power failures occur, fabric filters fail, and scrubber pumps fail -- even at best performers and despite the best efforts of companies to prevent and minimize such events. Industry can and does work to minimize such periods and the resulting emissions, but they do occur. Further, manufacturers of such equipment routinely make emission guarantees for normal operations and although they sometimes oversize equipment to account for some of the variability described above, it is very doubtful that vendors would provide sufficient numerical guarantees for equipment under all start-up, shutdown and malfunction situations.

Comment: Inclusion of an affirmative defense for start-up, shutdown, and malfunction
AECT opposes EPA's proposal to omit from the IB MACT proposed rule an affirmative defense for excess emissions of HAP during periods of start-up, shutdown, and malfunction ("SSM"). EPA's proposed rule unnecessarily disregards the special circumstance of excess emissions of HAP during SSM and EPA has seemingly broadened the D.C. Circuit's holding, by not only providing no SSM exclusions, but also by offering no alternative provisions addressing excess emissions during periods of SSM.

AECT urges EPA to include an affirmative defense during periods of SSM in the IB MACT proposed rule. Specifically, EPA should provide that, while periods of excess emissions during startup and shutdown would be considered violations, an owner could raise an affirmative defense. Nothing in the D.C. Circuit's opinion precludes EPA from including an affirmative defense for excess emissions during periods of SSM. In fact, doing so would be consistent with EPA's approval of similar State Implementation Plan (SIP) provisions and EPA's previous guidance on SSM.

Similar affirmative defense provisions have recently be approved into several states' SIPs. For example, both the Colorado SIP and the New Mexico SIP contain an affirmative defense for excess emissions during periods of startup and shutdown. It is important to note that when EPA approved the affirmative defense provisions, it stated that that affirmative defense provisions are "consistent with the provisions for startup and shutdown we suggested in our September 20, 1999 memorandum." (71 Fed. Reg. at 8959 74 Fed. Reg. at 46912).

In fact, the IB 1CR did not require any testing during SSM . Operations during boiler start-ups are different than normal plant operations. For many AECT members' it is simply not feasible from a technical or safety perspective to operate certain emissions control equipment during all parts of a startup or shutdown, or at least to operate such equipment "consistently effective" during all parts of a startup or shutdown. Without emissions data during these periods, EPA has absolutely no factual basis for concluding that the best performing units can achieve the proposed IVIACT limits during SSM events.

Including an affirmative defense is consistent with EPA's policy regarding exclusions during periods of SSM. Unlike an exclusion, an affirmative defense does not excuse a source from continuous compliance, The affirmative defense merely relieves the source of any penalty imposed as a result of non-compliance during a period of SS1V.1. It does not relieve the source of the requirement to comply With the applicable standard.

Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 11

Comment: The Proposed Limits Cannot Be Achieved During Periods of Start-up, Shut-down and Malfunction. While MidAmerican is mindful of the need to avoid complete exemptions during periods of start-up, shut-down and malfunction, alternative emission limits should be considered during these periods to account for such events. Clearly, the start-up of a boiler is an event that is anticipated and cannot be avoided; in fact, in order to comply with all the provisions of the proposed rule, many facilities will have to take outages to both install controls or to perform the requisite assessments that the proposed rule requires. As a consequence, facilities should not be forced into a situation that upon start-up, they are out of compliance with the emission standards, particularly for CO. Cold starts, when equipment temperature is low, will inevitably result in higher CO emissions for short periods of time. MidAmerican does not believe that EPA has appropriately accounted for higher levels of emissions during such periods. EPA should establish an alternative emission limit for startup periods based on boiler types and loads, as well as to account for variability during shutdown periods.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-2794.1
Comment Excerpt Number: 12

Comment: Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should set work practice requirements to address periods of malfunctions as well. As noted above, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . .” Similar to startups and shutdowns, malfunctions fit with the situations described in the definition of “not feasible to prescribe or enforce an emission standard” as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. As noted earlier, EPA acknowledges in the preamble to the Proposed Boiler Rule that it is “impracticable” to take periods of malfunctions into account when setting emissions standards given the “myriad different types of malfunctions that can occur across all sources in the category” and that “malfunctions can vary in frequency, degree, and duration, further complicating” the standard setting process. 75 Fed. Reg. 32013. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

For these reasons, NEDA/CAP believes that it is appropriate for EPA to revisit this issue. NEDA/CAP suggests that EPA propose work practice standards that would allow sources a certain time period for start-up, shutdown and malfunction events and, as long as certain procedures are followed, then compliance would be met. Those work practice standards should require the development and implementation of an emissions minimization plan that will result in (a) minimizing emissions during such events that would exceed otherwise applicable emission limitations, and (b) for malfunctions that will cause the unit to exceed otherwise applicable emission limitations, promptly identifying and implementing measures to remedy the malfunction. While there may be some instances where standard work practices can be identified for a type of source, NEDA/CAP cautions that overly prescriptive and non-facility-specific requirements can actually be counterproductive, restricting the operators’ flexibility in a way that hampers their ability to troubleshoot or respond to an event, or that compromises safety. The plan itself should not be incorporated into the Title V permit. The plan should be an evolving document, and it would be very cumbersome to have to seek a modification of the Title V permit every time the plan changed. If the details of the emissions minimization plan had to be made part of the permit, facilities would tend to make the plans less specific and therefore probably less useful. For the same reason, these plans should be maintained at the facility rather than being required to be submitted to the permitting authority with the Title V application or otherwise.

Alternatively, EPA could establish a threshold of exceedances as either a number or percentage of operating times that could occur during a quarterly or six month period before a violation occurs. This methodology is consistent with other MACT standards such as 40 CFR 63 Subparts S and MM.

Comment Excerpt Number: 13

Comment: The IB ICR did not require any testing during start-up, shutdown and malfunction events. Without emissions data during these periods, EPA has absolutely no factual basis for concluding that the best performing units can achieve the proposed MACT limits during start-up, shutdown and malfunction (SSM) events. EPA must obtain emission information during SSM events in order to set standards during SSM. Alternatively, work practice standards are far more appropriate since measuring emissions during SSM is often not possible and generally not feasible.

Although Southern Company does not have emission test data during periods of SSM for our oil, natural gas, or biomass-fired boilers, we do have continuous mercury emissions information from some of our coal-fired utility boilers. We have learned at our coal plants that periods of SSM may impact emission control performance and affect our ability to meet emission standards during SSM events.

Operationally, SSM time is minimized since these events lead to increased wear and tear on plant components. Nevertheless, SSM events are unavoidable and make up a small part of the plant's normal operating cycle.

Periods of startup must account for the length of the boiler startup as well as the system startup (e.g., startup of the emission controls). Startup of emission controls to normal operating conditions requires as much and generally more time than the startup of the boiler itself. Although longer averaging times may account for this startup (assuming reasonable emission limits), it will likely be impossible to meet 24-hour block averages, considering startups can last > 36 hours, and be very difficult to meet 30-day rolling averages, especially if there is more than one startup or malfunction in any 30 day period. Unless EPA gathers data for emission during SSM events and considers acceptable emission limits with averaging times long enough to account for normal plant startups and malfunctions (e.g., annual averages), EPA should not set emission standards during these events. Work practices standards are far more appropriate during periods of start-up, shutdown and malfunction.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 14

Comment: Plant startups fall into two categories – plant startup following a forced (or unplanned) outage (hot startup) and plant startup following a planned outage (cold start). Both outage types occur at any facility and are required for maintenance purposes. These types of plant startups mainly differ in their duration and frequency. Hot plant startups following a forced outage are more common and typically shorter in duration. For example, a coal plant may startup following a forced outage >10 times per year. Long extended maintenance outages are planned in advance and last for several weeks, but they occur annually or even farther apart.

All plant startups are composed of multiple equipment startups, ranging from the startup of small equipment (e.g. thermocouples) to large reactors -- e.g. boiler, SCR, wet flue gas desulfurization (FGD or scrubber) system. Each of these systems necessarily has a different time constant associated with its startup. During this period, equipment may operate far outside of its design conditions. If the equipment is part of HAPs control, this type of operation can lead to high emission events during plant startup. See submittal for data from two large coal-fired utility plants that show: 1) the duration of plant startups and 2) how the startup cycle affects mercury emissions.

Figure 1 shows the cold startup of a coal-fired plant equipped with oil igniters. This startup followed a planned outage. During oil-firing, the SCR is fully bypassed in order to prevent catalyst poisoning and potential fire hazards. Full bypass continues until coal-firing begins and stable boiler operation is achieved. Operational tie-in of the SCR is initiated by a gradual opening of the SCR inlet dampers. This partial bypass period is required to minimize thermal stress, ammonium bisulfate formation, and acid corrosion. Mercury emissions are elevated until all of the flue gas passes through the SCR. Like other high emission events, these startup periods could represent a significant portion of a plant's emissions during a given averaging period.

Figure 2 of the submittal shows an example of an unplanned plant shutdown and hot plant startup following a short forced outage. The shutdown of the plant in this outage did not result in any unusual mercury emissions. However, the startup cycle did impact emissions significantly. The boiler while being started reaches full rated capacity in 10 hours. Full and partial SCR bypass lasts only 8 hours. During this period, mercury emissions are elevated. However, note that mercury emissions remain above their pre-outage average value of ~1 lb/TBtu even after the SCR bypass has ended (see both Figures 1 and 2). This phenomenon is not well understood, but may be due to desorption of mercury from the hot catalyst or mercury re-emission. Thus, in terms of Hg emissions for a plant equipped with an SCR and wet FGD system, the startup period may last >36 hours.

Comment: Malfunctions can be of two different types – malfunction of the emissions control equipment controlling HAPs emissions, or malfunction of the boiler equipment unrelated to the emissions control systems. Clearly, malfunctions of the emissions control systems should warrant corrective action, but system malfunctions can result in increased emissions unrelated to the operation of the emissions controls. For example, if a component malfunction requires the operation of the boiler be less than the minimum temperature for a SCR, then the SCR would have to be placed in bypass while the flue gas temperature is too low, and this action could increase mercury emissions in the examples above.

Comment: EPA has made a similar mistake with regard to its proposal to not set a separate standard for periods of startup, shutdown, and malfunction. On the one hand, EPA asserts that "[t]he standards we are proposing are daily or monthly averages ... [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." On the other hand, EPA uses short-term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction. To assure that startup, shutdown and malfunction are appropriately accommodated, EPA must either assure that the data on which the standard is based include representative data from such periods or, alternatively, set a separate work practice standard to properly accommodate startup, shutdown and malfunction.

Comment: SSM

EPA has proposed that their averaging time basis for compliance with the emissions limits would be adequate to cover startup and shutdown periods and malfunctions are simply not addressed in that they should not occur. DuPont believes this approach is unworkable and fails to recognize the realities of operating the many types of boilers and process heaters. As a base issue, EPA has not utilized long term emissions data such as CO CEMS data to adjust emissions test data to be representative of actual operating data over time. Additionally, while a couple of the 30 day CEMS test units included startups and shutdowns within the period, that was not done for all units. So there is no allowance for emissions during SS periods in the proposed limits. It is not feasible to conduct emissions testing during SSM periods due to the variable nature of those conditions. It is not feasible to conduct emissions testing during malfunctions since by definition there are operational problems that could indeed be safety issues during those periods. Therefore, trying to incorporate SSM periods into an emission limit that must be met at all times is fraught with problems. We are concerned that if such limits were set, operators could be placed in an untenable position of trying to operate equipment and not exceed emissions limits, and be tempted to take shortcuts that could place equipment and personnel at risk relative to equipment integrity and safety.

Therefore, we urge EPA to utilize its discretion to allow facilities to establish site and unit-specific startup and shutdown plans as a work practice approach during SS periods so that appropriate practices are followed with minimization of emissions during those periods to the extent practical. Malfunctions should also be managed similarly with a malfunction plan, so that operators are knowledgeable and trained to recognize potential malfunctions and to take appropriate actions which allow for safety as of utmost importance with protection of equipment integrity.

Comment: The MACT floor analysis does not account for effects of startup, shutdown, or malfunction (SSM) on combustion-related HAPs emissions (CO and dioxin/furans) and PM emissions for new or existing units. This is critical for units that are required to demonstrate continuous compliance with the CO limit using a CO CEMS and with the PM limits using PM CEMS, since 40 CFR Part 63 no longer includes exemptions for SSM periods.
EPA does not have sufficient data (neither reference method nor CEMS data) for those units in the MACT floor to address variability in PM emissions due to startup/shutdown. It is also questionable whether representative measurements could even be obtained during boiler startup/shutdown due to the dynamic flue gas conditions and technical limitations associated with the measurement technology. For these reasons, EPA must either assure that the data on which the standard is based include representative data from such periods or, alternatively, set a separate work practice standard to properly accommodate startup, shutdown, and malfunction.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA Has No Basis to Expect That Operating Parameter Limits Established During Performance Tests Will Be Achievable During Startup, Shutdown, and Malfunction
Duke Energy is very concerned about the potential for enforcement of operating parameter and opacity limits during periods of startup, shutdown, and in the event of equipment malfunction. When EPA finalized its rule in 2004 with enforceable operating parameters, it did so with a rule that also made clear that those limits did not apply during periods of "startup, shutdown, and malfunction." 40 C.F.R. 63.7505(a), 69 Fed. Reg. at 55,254. EPA's current proposal contains no such exception, but instead would allow enforcement of deviations from operating parameters during periods of startup and shutdown, when controls would not be expected to be operating at the same levels as during performance tests, and due solely to equipment malfunctions. In the preamble, EPA discusses its approach to these events. 75 Fed. Reg. 32013. Regarding startup and shutdown, EPA asserts that it has taken these periods into account by using GEMS data from best performing units that include periods of startup and shutdown, and by proposing use of "daily or monthly averages." Regarding malfunctions, EPA asserts that it would use a variety of information to determine an appropriate response to exceedances caused by equipment malfunction.
EPA's preamble assertions regarding startup and shutdown are inapplicable to control device operating parameter limits, which are based on 12-hour averages (not daily or monthly averages) established during performance test (not based on GEMS data that include startup and shutdown). Even a daily block average, as proposed for opacity, does not provide sufficient protection if the unit does not startup or shutdown at exactly midnight, since there might not be sufficient data under normal operating conditions to compensate for the startup or shutdown period. In short, EPA has made absolutely no allowance in its rules for periods of startup and shutdown yet it has specific evidence that these periods are distinctively different. To the contrary, EPA has proposed to require sources to establish control device operating parameters levels that are dependent upon load during periods of "maximum normal operating load," and then maintain those levels during periods other than maximum normal operating load, including startup and shutdown. EPA's proposal is patently unreasonable. EPA must address these periods in some other manner, for example by establishing simple work practice standards in lieu of operating parameters.

EPA's promise to address periods of equipment malfunction by considering other information before enforcing exceedances of operating limits provide little comfort, especially given the risk of citizen suits. Although Duke Energy appreciates EPA's proposal to make clear that "deviations" of operating limits are not necessarily violations, nothing in EPA's proposal would prevent EPA, a state, or a plaintiff in a citizen suit from simply determining in their "discretion" that any particular exceedance constitutes a violation. Proposed § 63.7575. MACT standards are technology-based standards and must recognize that even the best performing technology occasionally fails.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Operating Parameter Limits Established During Performance Tests Will Not Be Achievable During Startup, Shutdown and Malfunction
Proposed Section 63.7540 requires continuous compliance with non-monitored limits, such as HCL and Hg, by establishing operating parameter (such as scrubber pH, slurry flow, pressure drop, liquid flow-rated and sorbent injection rate for scrubbers) maximums and minimums that would be established during initial compliance tests (required by 63.7530) to meet the HCL and Hg limits. Operation outside of these limits will be considered a deviation from the operating limits. When EPA finalized its rule in 2004 with enforceable operating parameters, it made clear that those limits did not apply during periods of "startup, shutdown, and malfunction." The current proposal contains no such exception, but instead would allow enforcement of deviations from operating parameters during periods of startup and shutdown, when controls would not be expected to be operating at the same levels as during performance tests, and due solely to equipment malfunctions. In the preamble, EPA asserts that it has taken these periods into account by using CEMS data from best performing units that include periods of startup and shutdown, and by proposing use of "daily or monthly averages." Regarding malfunctions, EPA asserts that it would use a variety of information to determine an appropriate response to exceedances caused by equipment malfunction". These assertions regarding startup and shutdown are inapplicable to control device operating parameter limits, which are based on 12-hour averages (not daily or

monthly averages) established during performance test (not based on CEMS data that include startup and shutdown). Even a daily block average, as proposed for opacity, does not provide sufficient protection if the unit does not startup or shutdown at exactly midnight, since there might not be sufficient data under normal operating conditions to compensate for the startup or shutdown period. In short, no allowance for periods of startup and shutdown has been provided in the proposed rule. To the contrary, sources are required to establish control device operating parameters levels that are dependent upon load during periods of "maximum normal operating load," and then maintain those levels during periods other than maximum normal operating load, including startup and shutdown. These periods must be addressed by allowing sources to identify alternative parameters or by establishing simple work practice standards for these periods.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: RMB recommends an alternative approach for addressing load-related variability in CO and D/F emissions based on a comparison of CO levels during periods of startup/shutdown to normal, steady-state operation for several different units within the same fuel/boiler-type subcategory.

This would require a review of the unit operating data to determine each startup/shutdown period. A variability factor (Ksusd) could be established for each unit by calculating the average CO emissions during startup/shutdown (Csusd) divided by the average CO emissions during normal, steady-state operation (Css). This could be conducted for each startup/shutdown event in the observation period and averaged for the unit. An overall variability factor could then be calculated based on an average Ksusd for all units in the boiler-type subcategory. The load-related variability factor would be applied in addition to the 99% UPL variability analysis, which characterizes inter-unit steady-state operating variability and measurement-related variability. RMB notes that this alternative approach does not address malfunction-related variability since it would be impossible to establish a representative malfunction event. However, the use of a 30-day averaging period may help to offset this deficiency.

Unfortunately, EPA does not have sufficient CEMS data in the ICR database for those units in the MACT floor pool to address load-related variability using the alternative approach. EPA will need to obtain additional data in order to conduct this analysis. In obtaining this data, RMB recommends that EPA include periods of startup/shutdown (particularly cold-start) that are representative of each boiler type.

Comment: The MACT floor analysis does not account for the effects of SSM on PM emissions for new or existing units. This is critical for those units that are required to demonstrate continuous compliance with the PM limit using a PM CEMS since Part 63 no longer includes exemptions for SSM periods. Furthermore, the relatively short proposed averaging period (24 hour block) would make compliance with these limits especially difficult, if not impossible, for most units.

EPA does not have sufficient data (neither reference method nor CEMS data) for those units in the MACT floor to address variability in PM emissions due to startup/shutdown. Moreover, RMB has concerns over whether representative measurements could even be obtained during boiler startup/shutdown due to the dynamic flue gas conditions and technical limitations associated with the measurement technology. For instance, changes in particle size distribution or unburned levels during startup affect PM CEMS measurement accuracy, particularly those using optically-based technologies.

Because the variability effects can not be adequately addressed, RMB recommends that EPA remove the requirement for the installation and use of PM CEMS as the continuous compliance determination method for coal and biomass sources with heat input ratings greater than 250 mmBtu/hr. Alternatively, sources could demonstrate a reasonable assurance of compliance based on opacity or parametric monitoring as EPA has already proposed for those units with heat input ratings < 250 mmBtu/hr. EPA could allow the installation and operation of a PM CEMS as an option for all sources, which is consistent with approach taken in the recent revisions to NSPS Subpart Da. However, in this case, RMB would recommend increasing the compliance averaging time (i.e. 30-day rolling average) in order to mitigate some of the effects of startup/shutdown.

Comment: EPA Needs to Further Develop Regulatory Requirements for Times of Start-Up, Shutdown, and Malfunction. EPA's proposed rule requires that emission limits apply at all times, including times of Start-up, Shutdown, and Malfunction (SSM). EPA needs to further develop the requirements for boilers and heaters during times of SSM. CO and oxygen levels will be significantly higher during an initial period of start-up when combusting gaseous fuels. This is due to the boiler operating during this transition time between zero load and the desired operating load. A gas fired boiler could have CO emissions 5 to 25 times above the proposed 1 ppmv limit for over 7 hours during this start-up mode. The following graph shows how CO concentrations change during times of start-up at a boiler that combusts as a mixture of natural gas and Gas2 fuels. [See submittal for figure, "Boiler 1 Startup."] Also, oxygen concentrations vary during times of start-up, making the CO correction to 3% oxygen a very significant one. For example, during times of start-up, the oxygen concentration may be ~ 15%, so the correction to 3% oxygen would be 17.9/5.9 or approximately a factor of 3. Even a small number of hours with high CO concentrations could create a situation where the source could not meet a low CO concentration level over a 30 day averaging period.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 74

Comment: Boilers and Process Heaters that combust other gaseous fuels - If these sources remain subject to a numerical emission standard vs. a work practice standard - These sources should be subject only to a work practice standard during SSM periods that requires the boiler or heater and any air pollution equipment to achieve steady state operating conditions within 24 hours from the commencement of start-up. In addition, since most of Dow's boilers/heaters do not start-up more than 1 time per quarter, EPA could limit the use of the work practice standard for 96 hours per year. Thus, similar to the recently promulgated Engine RICE MACT rule amendments, the boiler/heater would not be subject to a numerical emission standard for the hours that it takes to ramp up steam production and pressures. Adopting this approach would continue to minimize any HAP emissions from theses sources without jeopardizing the ability of the source to meet a CO emission level over a 30 day period.

Boilers that Combust Solid Fuels - Solid Fuel Boilers should be subject to the same type of work practice requirements as described above in comment #1 for gas fueled sources. This type of work practice would allow for the time required to start-up these types of boilers and to bring emission control equipment on-line such as an Electrostatic Precipitator (ESP).

Dow proposes the following regulatory text for EPA's consideration in section 63.7505(a):

Emission limits apply at all times, except during times of SSM where the SSM work practice requirements apply instead.

Comment: Item #2 from Table 9 Should be Deleted since the SSM Plans are not required by this proposed rule. EPA proposes in Table 9 of the proposed rule that the owner/operator should make an immediate startup, shutdown, and malfunction report if one has a startup, shutdown, or malfunction during the reporting period that is not consistent with the startup, shutdown, and malfunction plan, and if the source exceeds any applicable emission limitation in the relevant emission standard.

EPA should remove this requirement prior to publishing the final rule. In Table 10 of the proposed rule, EPA clearly notes that the requirements of 40 CFR 63.6(e)(3) (i.e., requirement to prepare a written SSM plan) do not apply.

Comment: Much, if not all, of the emission data used to establish the proposed limits are from performance tests conducted in response to EPA's Section 114 directive. Boilers were required to be tested "at loads that represents typical conditions" and "under normal operating conditions" which in the historical context of performing stack tests has meant relatively smooth operating conditions, exclusive of dramatic operating swings which may occur due to a variety of real-world conditions that can and do happen even in those best-performing units. Such ideal conditions are achievable only when all operations are functioning properly and smoothly which does not occur all the time. A problem is that these relatively smooth conditions do not ensure worst case emissions scenarios, which for example with CO is typically at low loads or in rapidly swinging loads, such as when a paper machine goes down or starts up suddenly. Despite EPA's comments to the contrary, periods of start-up, shutdown and malfunction are not represented in "normal operating conditions"; the proposed MACT limits do not account for SSM and therefore the standards should not apply during SSM periods. Instead, EPA should consider work practice standards during periods of SSM.

Comment: The standards proposed are not all daily or monthly averages as EPA purports. Initial compliance with the standards are based on the average of 3 4-hour stack test runs during a period representative of maximum emissions not daily or monthly averages. Continuing compliance is based on 12-hour block averages of CPMS data for several pollution control equipment configurations required for compliance with the rule. None of the stack test data collected during the ICR includes any startup or shutdown periods and therefore the MACT standards do not reflect the emission limitation achievable by the best performing 12 % of sources during these periods.

Comment: MPU believes the EPA grossly underestimated the impact that SSM will have on a boiler. Boilers have a maximum heat flux rate that may require eight to ten hours to bring a unit up to normal operating temperatures. During the start up phase, emissions such as carbon monoxide (CO) will be significantly elevated, as temperatures are too low for complete combustion. Attached please find a chart depicting CO operating data with the peaks occurring during SSM events. CO emissions will be lower when the boiler is online and stable, however we do not believe it is possible to average out the SSM emissions when operating in the proposed ranges. In addition, in today's energy markets such as the Midwest Independent System Operator (MISO) we believe it could become routine operation for smaller EGU units to shutdown on a daily basis as the energy may not be required at off peak times. These additional SSM events will exacerbate the situation and could force an EGU to leave a unit online even though it is not needed, resulting in unnecessary emissions. We recommend that EPA reevaluate and develop revised emission limits to address the SSM concerns.

Comment: US EPA maintains that the CEMS data used to establish standards included periods of startup and shutdown, however there is no indication in the CEMS data available in the record that this is true. In addition, the CEMS data available in the record does not include any liquid fuel boilers and because only CO CEMS were used the data is only representative of CO data. CO data by US EPA's own analysis is not representative of particulate HAPs, Hg, HCL or dioxin/furans. It provides no basis to assume that these other pollutants don't fluctuate significantly during startup, shutdown, malfunction or other transient periods and certainly provides no information on liquid fueled boilers which were not included in the CEMS data collected. US EPA can not definitively state that based on the record, the standards reflect emission rates that are achievable during startups, shutdowns, malfunctions or other transient events by the best performing 12 % of sources. Because US EPA cannot definitively state that, US EPA needs to revise the standards to reflect levels achievable during these periods by either collecting additional data or by exemption.

Comment: Because bagasse has such a high moisture content, it is not combustible in its natural state. Instead, bagasse first must be dried. Because bagasse naturally absorbs ambient moisture, the combustion process must follow directly after the drying process. As a result, bagasse boilers cannot startup by burning bagasse; another fuel is needed to fire up the boilers to begin the drying phase. U.S. Sugar's bagasse boilers generally use fuel oil until the boilers can run on bagasse, at which point the transition to 100% bagasse is phased in. Fuel oil, of course, has a different emissions profile than bagasse and all other biomass fuels. This results in entirely different emissions, both in type and quantity, during the startup period. Other biomass boilers that burn a dryer fuel available for use at startup may not experience the same degree of disparity between the startup and peak operating periods. Therefore, MACT Floors appropriate to bagasse-fueled boilers can only be determined by considering the unique startup process shared only among other bagasse-fueled boilers. A distinct subcategory is necessary to identify the true best performers among those facing similar challenges.

Response: See the preamble for discussion of combined grate/suspension firing subcategory, which includes bagasse units based on design features. The subcategory is not specific to fuel type. Please see the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: No Relief from Emission Limits during Maintenance/Startup/Shutdown and Alternate Operating Modes

The proposed CO emission standards for Gas 2 facilities appear to be based upon emission data from short term stack tests of the best performing sources during periods of high rates and steady state operation. Given the variability of CO emissions during episodes of maintenance, start-up, shutdown, variable production demands, stand-by operating modes, etc., even processes with the lowest combustion emissions cannot comply with the proposed emissions limits all the time.

Not allowing any exemptions or considerations for multiple operating modes under the proposed rule is inappropriate when no source can attain 100 % compliance.

Recommendation: The agency is requested to consider relief for such operations by 1). establishing more representative emission limits for such operations and 2). allowing longer averaging times in conjunction with more representative emission limits, or 3). using good work practices to minimize emissions instead of prescribing numerical standards.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: The DC Circuit's December 29, 2008 holding in the Sierra Club case that struck down a general Start Up / Shut Down & Malfunction (often referred to as SSM) exemption applicable to Section 112 MACT standards. The court held that a generic SSM exemption based on the general duty clause was overbroad and that compliance with a MACT had to be continuous.

Nonetheless, EPA must still recognize that SSM events will occur and must develop MACT emission limitations that take into account the elevated emission rates which occur during these unavoidable periods. The ICI Boiler MACT standard must be crafted such that the limits can be met continuously, 100% of the time, including during SSM events.

Comment: The emissions standards proposed in EPA's Boiler MACT Rule are meant to apply during normal operations as well as during periods of "Start-up, Shutdown, or. Malfunction (SSM)". However, in many cases, EPA utilized the results from stack tests (ICR phase II) that were based on three, one-hour runs, to set the MACT floor. These tests did not in most cases, represent emissions achieved during SSM periods. As a result, the proposed MACT standards are based on boilers operating under steady-state conditions, and we:believe, are unachievable during SSM periods. Many boilers experience extended periods of start-up, lasting anywhere from 18 to 24 hours, or longer. During the start-up period, boilers may switch fuels (e.g., fuel oil may be used to warm-up a coal-fired boiler) and alter the amount of combustion air fed into the combustion chamber in order to attain steady-state operations. It takes a considerable length of time for large boilers to reach steady-sate conditions, and as a result, emissions will in most cases, be higher during the start-up phase of operations. Malfunction episodes are unpredictable and the resulting emissions during these periods are usually much higher than during normal operations.

Therefore, GIEC urges EPA to consider work place standards during SSM periods in lieu of establishing specific numerical limitations. Emission rates from industrial boilers during SSM periods will vary greatly depending upon a number of operating variables as well as the type of boiler, and therefore, emission limitations cannot easily be established. GIEC believes that it makes more sense to require work place standards that minimize emissions to the extent practicable during SSM periods until such time that the boiler is either (1) placed into normal steady-state operation, (2) safely shut down, or, (3) returned to normal operation by taking corrective action to resolve the malfunction.

Commenter Name: Terry Walmsley
Commenter Affiliation: Fibrowatt LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2995.1
Comment Excerpt Number: 4

Comment: As stated in the Major Source Boiler Rule at 32050 and the Area Source Boiler Rule at 31926, a source must meet emission standards at all times during the operation of the plant, therefore this presumably would uniformly include during periods of Startup, Shutdown, and Malfunction ("SSM") . While EPA suggests that a uniform emission limit can encompass normal SSM, Fibrowatt believes that continuous compliance can be adversely impacted by a truncated daily averaging period. Fibrowatt further believes that this requirement can have practical problems associated with normal transitions through periods of SSM and supports an approach that would stipulate an alternative but enforceable limit during periods of startup and shutdown as opposed to a single uniform limit. Fibrowatt further requests that EPA provides more definitive guidelines on how periods of malfunction will be appropriately addressed in the rules and address emission limit applicability during such unpredictable occurrences.

Comment: US EPA also apparently maintains that because boilers "normally" do not startup and shutdown daily so it isn't important for the standards to reflect SSM periods. Whether or not boilers startup and shutdown daily, however, is irrelevant to the standards setting process. US EPA boldly professes that these periods are "routine operations" and if this is the case, the standards should reflect emission rates that the best performing boilers are able to achieve during these "routine operations". US EPA states it believes boilers can meet these standards during startup and shutdown periods, but provides no data which supports that argument. US EPA needs to provide actual data to support its claims that the best performing sources meet these standards during startups, shutdown and/or malfunction periods.

Comment: Establish limits that take start up and shut down into account, exempt start up and shut down or establish separate start up and shut down standards since these operating periods have different emission profiles. Existing permit limits allow for emissions during start-up and shutdown. Most power plants have CO limits specific to startup and shutdown events, when emission concentrations are higher for a short period of time until normal operating conditions are achieved, complete combustion is occurring, and the control equipment commences and stabilizes as designed. CO standards in the proposed Boiler MACT Rule do not accommodate for this. We suggest that existing permit limits be used for these periods.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Separate Emissions Standards Should Be Developed for Periods of Startup, Shutdown and Malfunction. Emissions of some HAPS are more difficult to control during startup, shutdown and malfunction (SSM) conditions, particularly in boilers that co-fire biomass with coal. EPA's assertion that "[t]he standards we are proposing are daily or monthly averages..." implies that the longer averaging periods will be able to absorb any higher emission rate during the SSM period, is flawed. For example, startups can take the greater part of a day, likely resulting in exceedances of any daily standard, even though all efforts are taken to remain in compliance. A higher emission rate during startup may not result in high mass emissions due to the lower startup fuel feed rates, so a significant environmental impact should not be expected. Consideration should be given for separate emission standards during startup, shutdown and malfunction periods that take into consideration the relatively low mass emissions during those periods.

Comment: Under normal and predictable startup operations, a requirement to continuously meet uniform emission limits may be difficult for certain types of biomass fuels as the unit progresses through the normal transition from startup fuel to biomass fuel. Although Fibrowatt utilizes a low emission startup fuel (expected to be propane) and it is reasonable to maintain emission standards while on startup fuel, the switch from propane to certain biomass fuels in a spreader=stoke boiler can typically result in a significant variation in carbon monoxide (CO) emissions that can adversely effect the CO average (especially during truncated daily operations) and therefore compliance demonstration. Including such startup period in the normal compliance determination for CO may not be achievable under all conditions and all biomass fuels where the normally startup period can run for a long period of time, for example during a "cold=start ."

Comment: The IB ICR did not require any testing during start-up, shutdown and malfunction events. Without emissions data during these periods, EPA has no factual basis for concluding that the best performing units can achieve the proposed MACT limits during start-up, shutdown and malfunction events. Operations during boiler start-ups are different than normal plant operations. Certain plant components must be started in a specific sequence in order to ensure that steady state operations can be achieved. During start-up not all pieces of control equipment will be operating at peak efficiency. Progresss Energy believes that work practice standards are far more appropriate during periods of start-up, shutdown and malfunction.

Comment: For periods of startup and shutdown, we request that EPA consider a mass limit (lb/hr) equivalent to the lb/MMBtu or ppm concentration based limit at maximum load. The health effects due to HAP emissions are no worse or better during startup than at full load based on the same mass emission rate, however this is one way that real world compliance could be assured. This approach is commonly used in setting PSD limitations that govern startup and shut down.

Comment: Designing a control system to handle the start up emissions of boilers would require an additional major investment in controls and energy with only limited use. It is certainly possible that a control system designed to handle start up / shut down emissions could create more pollution than it would prevent. We also believe that the start up / shut down limitations will require additional procedures that could delay bringing a unit online and unintended consequences could result from this action. In addition, we believe it will be very difficult to demonstrate compliance during start up / shut down periods as conditions continuously and rapidly change as the boiler comes up on load and stabilizes.

Comment: We are very concerned that EPA proposal does not set a separate standard for periods of startup, shutdown, and malfunction. On the one hand, EPA asserts that “[t]he standards we are proposing are daily or monthly averages … [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards.” [75 Fed. Reg. at 32013.] On the other hand, EPA uses short term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Furthermore, the Major Source Boiler Rule at 32013 and the Area Source Boiler Rule at 31901 suggest that emissions during malfunction events would represent an alternative operating mode but does not resolve how this alternative operating mode would be adequately dealt with in the proposed rule. While the supporting language in the Major Source Boiler Rule at 32013 and the Area Source Boiler Rule at 31902 suggest that EPA will determine an appropriate response to the malfunction event, this is not adequately addressed in the proposed Major Source Boiler Rule and the Area Source Boiler Rule as it relates to limit applicability "at all times."

Fibrowatt requests that EPA better=defines its "appropriate response" to malfunction events so regulated parties under the Major Source Boiler Rule and the Area Source Boiler Rule can properly evaluate measures required during such malfunction events. Fibrowatt further requests an additional comment period be given for regulated parties to assess what EPA establishes as good operating practices during malfunction events and associated consequences to EPA's "appropriate response" to such events.

Comment: The proposed rules provide no recognition of the elevated emissions levels associated with the startup of biomass boilers. In the proposed rule EPA grants no recognition of the realities of biomass boiler startups, imposing the standards applicable to normal operation to days where startups occur. The only recognition of the anomalous conditions that exist during startup was to state that 24 hours averaging would enable boiler operators to demonstrate compliance notwithstanding startup. For example, startups with ESPs can routinely take 6 to 8 hours and opacity, as recorded by a continuous opacity monitor, can reach 90 percent. It is known that not all of those readings accurately reflect opacity as considerable moisture is driven off the kindling fuel and the interior surfaces of the boiler, resulting in water vapor that is inaccurately read as opacity. However, there is also significant opacity during startup that is not capable of being reduced as the control equipment cannot be energized until the moisture is driven off and the interior surfaces adequately warmed up. Rushing this process can result in damage to control equipment and explosion concerns. As a result, notwithstanding good operation, it is mathematically impossible to average the startup opacity conditions with the opacity once normal operations have commenced to comply with a 10 percent opacity standard applicable to those biomass boilers employing ESPs or scrubbers (the vast majority of the controlled boilers in this subcategory).

Comment Excerpt Number: 7

Comment: After reading the proposed standards, we understand that EPA believes that a source will not have any problems with demonstrating compliance with CO emissions using a 30-day rolling average. Hampton agrees with this as long as emissions during start-up, shut down, and malfunction are not used in the calculation of the 30-day rolling average. Hampton operates CEMS continuously and has data collected during startups which show that best management practices for controlling CO emissions under normal operations do not work during a startup. Additionally, start-up and shutdown periods are not reflective of normal operating conditions, or anywhere near the 90 percent of load that the standard was based upon. Therefore Hampton believes that a start-up, shutdown, or malfunction is not normal operations and therefore the emissions should not be used when calculating compliance with a daily or monthly average. Most of our shutdowns and start-ups relate to difficult market conditions wherein the entire sawmill is shut down for a period of time until customer demand returns. We believe this will continue during the economic recovery and into the future.

Commenter Name: Catherine W. McCuthen
Commenter Affiliation: Blue Heron Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2892.1
Comment Excerpt Number: 8

Comment: We strongly encourage EPA to develop a startup exception to compliance with the work practice standards. Other recently promulgated NESHAPs have recognized that it is impossible to demonstrate compliance with emission standards during startup conditions and have allowed sources a reasonable period where they do not need to demonstrate compliance with the limits. For example, the Subpart ZZZZ NESHAP allows natural gas and diesel fired engines a 30 minute startup period during which the standards do not apply. If this can be allowed for fossil fuel fired units such as reciprocating internal combustion engines, a similar approach should be recognized for biomass boilers. Therefore, we recommend that EPA revise the rules to allow an 8 hour startup period during which the limits do not apply. Because this time may not be adequate for startup of some larger boilers without any supplementary fuel capability, we also suggest that EPA clarify that sources can apply to EPA for a longer startup time period.

Comment: EPA established the MACT floor limits based on testing conducted at steady state (and high load) conditions, so it cannot directly apply the data to startup, shutdown and malfunction (SSM) conditions.
The boiler MACT rule requires sources to maintain compliance with the same standards during startup, shutdown and malfunction (SSM) conditions as during normal full load conditions. However, EPA did not consider the expected variability in emissions during SSM and low loads when setting the standards. Without this variability in the standards, even the best performing sources are likely to be unable to comply under SSM or changing load conditions.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Mick Baranko
Commenter Affiliation: Douglas County Forest Products
Document Control Number: EPA-HQ-OAR-2002-0058-2856.1
Comment Excerpt Number: 8

Comment: The proposed rules provide no recognition of the elevated emissions levels associated with the startup of biomass boilers. In order to safely start up a biomass boiler without risk of causing explosion and avoid undue stress to the boiler, it is necessary to heat up the boiler slowly and without the benefit of particulate controls. EPA has recognized that until combustion is stable and the boiler has reached an exhaust temperature of 250F, it is not safe to energize an ESP. This fact has been recognized in prior rules such as the Boiler NSPS. In the proposed rule EPA grants no recognition of the realities of biomass boiler startups, imposing the standards applicable to normal operation to days where startups occur. The only recognition of the anomalous conditions that exist during startup was to state that 24 hours averaging would enable boiler operators to demonstrate compliance notwithstanding startup. This is grossly inaccurate. Startups can routinely take 6 to 8 hours and opacity, as recorded by a continuous opacity monitor, can reach 90 percent. It is known that not all of those readings accurately reflect opacity as considerable moisture is driven off the kindling fuel and the interior surfaces of the boiler, resulting in water vapor that is inaccurately read as opacity. However, there is also significant opacity during startup that is not capable of being reduced as the control equipment cannot be energized until the moisture is driven off and the interior surfaces adequately warmed up. Rushing this process can result in damage to control equipment and explosion concerns. As a result, notwithstanding good operation, it is mathematically impossible to average the startup opacity conditions with the opacity once normal operations have commenced to comply with a 10 percent opacity standard applicable to those biomass boilers employing ESPs or scrubbers (the vast majority of the controlled boilers in this subcategory).

Document Control Number: EPA-HQ-OAR-2002-0058-2774.1
Comment Excerpt Number: 8

Comment: EPA makes a similar mistake with regard to its proposal not to set a separate standard for periods of startup, shutdown, and malfunction (SSM). On the one hand, EPA asserts that "[t]he standards we are proposing are daily or monthly averages ... [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." On the other hand, EPA uses short term performance test results to set the standards rather than the results of longterm CEMS monitoring. Occurrences of malfunctions are entirely unpredictable, in terms of when, for what reason, and for how long. Therefore, inclusion of emission limitations for malfunction cannot be justified on any technical basis. All permits in California have specific provisions for malfunction, which should be respected and replicated by the EPA. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction, if such SSM periods are intended to be covered by the emission limitations.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Brad James

Comment Excerpt Number: 9

Comment: EPA has proposed to include startup and shutdown in the same MACT standard as peak operations. This result is neither reasonable nor required by case law.

In Sierra Club v. EPA, 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 130 S. Ct. 1735 (201), the D.C. Circuit held that EPA could not exempt periods of startup and shutdown from MACT standards. The court based its holding on CAA's requirement that the MACT standards apply continuously. Id. at 1027-28 (discussing interaction between sections 112(d) and 302(k)). The court did not, however, hold that the MACT standards for periods of startup and shutdown must equal the MACT standards during peak operations, or that there be one uniform MACT standard that applies during all periods. To the contrary, the court observed that that section 302(k) does not "necessarily" require "continuously applying a single standard." Id. at 1027. The court merely held that some MACT standard must apply during periods of startup and shutdown.

The best way to control for the differences between startup and shutdown periods and peak operation periods is to have one MACT standard govern startup and shutdown and another MACT standard govern peak operations. Such a result clearly would not run afoul of Sierra Club's holding because MACT standards will apply continuously during boiler operations.

Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 9

Comment: Many commenters have addressed the need for a separate standard for startup, shutdown and malfunction periods. HOVENSA supports those comments, particularly for malfunctions where the proposed rule affords no relief whatsoever despite a requirement for MACT standards to be met “continuously.” HOVENSA notes that while the DC Circuit struck down the general SSM work practice standard in 40 CFR 63.6, the court’s opinion in Sierra Club appears to invite EPA to adopt similar standards for SSM events under Section 112(h). HOVENSA urges EPA to adopt an SSM work practice standard essentially similar to 63.6(e), particularly for petroleum refineries because of process variability discussed below. This variability is even more significant for island/non-continental facilities.

Response: See the preamble for discussion of the non-continental unit subcategory and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Edward E. Quick
Commenter Affiliation: Celanese International Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2840.1
Comment Excerpt Number: 9

Comment: EPA has proposed standards that are not technically achievable by not considering operation during startup, shutdown and malfunction (SSM) or changes in rate when establishing the emission standards.
The proposed rule requires affected sources to maintain compliance during startup, shutdown and malfunction (SSM). However, when developing the proposed rule, EPA considered SSM only when developing the CO emissions standard for coal fired sources and, as such, is only achievable for those coal fired sources.

Emissions of other pollutants (PM, mercury, HCl, and D/F) are just as likely to increase during periods of SSM. Both combustion and pollution control device performance are variable during SSM and changes in rate.

The MACT floor for pollutants other than CO was established based on emission testing conducted at steady-state, high load conditions. These conditions may be achievable during a three-run emissions test, but not during all operating conditions.
In order to properly consider SSM and not only steady-state conditions, EPA must either:
-apply the emission standards at all times except during SSM and allow work practice standards to be implemented during SSM, or
-consider periods of SSM in the MACT floor analysis, and implement all emissions standards on a 30-day rolling average basis (this would incorporate rate changes for boilers and process heaters).
Because of the cost of continuous HCl and mercury monitoring systems, most affected sources would likely demonstrate compliance using parametric monitoring systems. There is no technical justification that would prevent an affected source from demonstrating compliance on a 30-day rolling average, whether continuous emissions monitors or continuous parametric monitoring systems are used.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Paul N. Cicio
Commenter Affiliation: Industrial Energy Consumers of America
Document Control Number: EPA-HQ-OAR-2002-0058-2752.1
Comment Excerpt Number: 10

Comment: Emissions of all regulated pollutants are likely to increase during periods of SSM. Combustion and pollution control device performance both are variable during SSM and changes

in rate. While EPA surely understands that even top performing units suffer malfunctions, the small snapshot of data used by EPA to determine these emission standards do not take these events into account. If the emissions standards are applied at all times including SSM, the MACT floor analysis must consider emissions data taken during those periods.
For example, numerous units currently operate with Carbon Monoxide (CO) Continuous Emissions Monitoring Systems (CEMS). IECA encourages EPA to collect CO data from sources equipped with CO CEMS, and analyze the data and especially the effect of Startups, Shutdowns and Malfunctions. EPA should revise its standards to account for the significant variability that occurs during SSMs by either:
(1) Establishing a work practices standard instead of an emissions standard to minimize emissions of CO during SSMs, or
(2) Establishing a separate CO emissions standard that would apply during SSMs, which would reflect the real variability in CO emissions during these events, or
(3) Raising the CO average emission standard so that sources can comply when SSM data is included.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Brad James

Document Control Number: EPA-HQ-OAR-2002-0058-2853.1
Comment Excerpt Number: 10

Comment: In the context of bagasse boilers, a separate MACT treatment for startup and shutdown is far more appropriate than the current approach. Due to the high moisture content of bagasse that requires drying before it can be used as fuel, bagasse-fueled boilers require a different fuel source and unique operating procedures during the startup process. This alternate fuel source possesses a completely distinct emission profile than bagasse. Accordingly, the MACT Floor applicable to bagasse boilers during peak operations should differ from that applicable during the startup period.

However, EPA’s proposed MACT standard applies during all modes of operation including startup and shutdown, but was not based on any data collected during startup or shutdown, or other “adverse circumstances which can reasonably be expected to recur.” This further invalidates the proposed standards as they were not “achieved under the worst foreseeable circumstances.”

Response: See the preamble for discussion of a combined grate/suspension firing subcategory. The subcategory includes bagasse units, however is based on design features and is not specific to fuel type. See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: We question the validity of establishing limits during startup and shutdown in this manner.. For example, CO emissions spike during periods of startup and shutdown, often to levels that are orders of magnitude greater than the average values achieved during normal operation. The magnitude of these spikes is so severe in comparison to the limit, that we doubt any existing units would be able to meet a limit of 1 ppm. And while it is true, as EPA states on page 32013 of the preamble, that solid fuel boilers do not normally start up and shut down more than once per day, liquid fuel-fired boilers have that capability. Imposition of such severe limits would eliminate that operating scenario.
Also, there are many units that are primarily run to test the unit's operating capabilities. These units are run for only a short time at high loads in a given operating run. The high concentrations during startup and shutdown severely skew the average concentrations. This also creates issues with compliance demonstration, as for many units, compliance is demonstrated with the average of three 1-hour long stack tests using EPA Method 10 conducted at maximum operating load. This testing method was not developed with startup and shutdown operations in mind.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA has mandated that the proposed emission standards apply at all times, including startup and shutdown. EPA reasons (75 FR at 32012-32013) that the daily or monthly averages take these episodes into account. There appears to be a mathematical problem in using concentration levels corrected to an O2 level under startup conditions. Elevated O2 levels seen during startup result in highly inflated PPM values (we refer to this as "data blowup") that cannot be compensated for in a longer averaging time. For example, in the first hour of startup when the O2 levels are near ambient levels, the O2 correction calculations provided for in Method 19 of 40 CFR 60 Appendix B yield invalid numbers. If the O2 monitor reads 20.9% (common for the first hour in startup), the emissions in corrected PPM is equal to infinity. If the O2 monitor reads 21% at the beginning of a startup (possible, given the accuracy of the instrument) the corrected PPM value will be a huge negative number. The excessively high PPM corrected values will continue for the first couple hours of startup and it will take up to 10 hours before the O2 level reaches a level close to 7%, at which point the mathematical "penalty" will stop. The same can occur in a shutdown, although for a shorter amount of time. These very high corrected values occur even when actual emissions are quite small. No averaging time will compensate for the extremely high values seen when using a concentration corrected to a given percentage of O2 during this time. We have corrected our operating permits in all cases that eliminates the use of a PPM corrected value (or a lb/MMBtu value, which in Method 19 carries the same mathematical problem see equations 19-1 to 19-3) during startup or shutdown conditions. We instead rely on mass emission rate values, which is practical on a unit-by-unit basis considering actual size.

Comment: EPA does not provide sufficient justification for the averaging times used to demonstrate compliance with the HCl and mercury emission limits.
Because of the variability in fuels and fuel quality, the requirement to demonstrate compliance during SSM conditions, and the inaccuracy of compliance measurement methods, the proposed approach is not acceptable. In light of this, the emissions limits for PM, HCl, and mercury limitations should be enforced on a 30-day rolling average. Because of the cost of continuous HCl and mercury monitoring systems, most affected sources would likely demonstrate compliance using parametric monitoring systems. There is no technical justification that would prevent an affected source from demonstrating compliance on a 30-day rolling average, whether continuous emissions monitors or continuous parametric monitoring systems are used. Since emissions testing results were not representative of the full range of operating conditions, such as SSM, the 3 hour test results cannot be used to set standards across the full range of operating conditions. If EPA chooses to set the standard across this range of operating conditions, longer averaging times minimize the compliance impact without impacting the overall emissions released to the environment.

As an alternative to applying the emissions standards on a 30-day rolling average, EPA may apply the emission standards at all times except during SSM and allow work practice standards to be implemented during SSM.

Comment: Before setting a national standard that includes SSM in a 30-day rolling average, the EPA should collect a minimum of 30 days of continuous data, including SSM periods, and use that data to set the standard.

If the emissions limits are to include SSM, then the units that are setting the limits should be continuously monitored for CO and PM to determine the impact to the stack test average. Of the six units that were continuously monitored for CO, the CO was considerably higher for units that had SSM conditions included in their data sets. No units were continuously monitored for PM as is proposed by the EPA. Table 1 illustrates the impact of SSM on CO readings. [See submittal for Table 1, EPA data related to continuous monitoring of CO.]

The data tabulated illustrates the potential impact of including SSM conditions for CO on solid fuels only. The impact on liquid and gaseous fuels cannot be ascertained due to a lack of data. For three units, continuously monitored and including SSM conditions, the CO is considerably higher than that of the stack test data.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA states that they have taken into account startup and shutdown periods. See 75 Fed. Reg. 32,012-32,013, ("In establishing the standards in this rule, EPA has taken into account startup and shutdown periods and, for the reasons explained below, has not established different standards for those periods. The standards that we are proposing are daily or monthly averages. Continuous emission monitoring data obtained from best performing units, and used in establishing the standards, include periods of startup and shutdown"). This statement is false. EPA claimed these were the "best performing units", when they meant "best performing unit for that pollutant only" as EPA's proposed standards for other pollutants were based on all different units (see previous comment). Further, the data utilized for establishing the standards in fact does not include startup and shutdown. In establishing the CO MACT standard for biomass suspension burners / dutch ovens, EPA relied on the following two sets of data: 1) One-time, short term stack test data for suspension burners / dutch ovens firing biomass during normal operation, and 2) Continuous emissions monitoring system (CEMS) data for a single biomass suspension burner during a period of fluctuations in load (i.e., 17% - 77% capacity).

The one-time, short term stack test data (the bulk of the emissions data reviewed) did not include startup or shutdown. And the single set of CEMS data which EPA specifically points to in the proposed Boiler MACT also does not include any data below 17% load – never going to zero which would be representative of a startup and shutdown, not to mention the use of alternate fuels specific to startup (as required for bagasse boilers).

While it is well documented that CO emissions are higher during periods of startup than during normal operation, it should not be the only pollutant considered to have potentially higher startup and shutdown emissions. Most control devices are not designed to be at their peak efficiency except during normal operation, and many cannot be operated during startup for safety reasons. Because EPA has established standards based on data the relies on the reductions of other pollutants from these control devices operating only at peak efficiency during normal operation, they have also erred in establishing "achievable" standards during startup and shutdown for all pollutants.

Therefore, EPA cannot claim that extending the averaging period for CO only should accommodate these routine and expected modes of operation without data showing as such. EPA has performed no such analysis to demonstrate that all standards set are achievable "under most adverse circumstances." The standards were based on data from limited, one-time, short-term stack tests during normal operation that are neither the same averaging period, the same monitoring requirements (stack testing vs. CEMS), nor encompassing of the "adverse circumstances which can reasonably be expected to recur." EPA has instead established arbitrary standards based on narrow data and incorrect assumptions.

Only by gathering data specific to the startup and shutdown periods can a suitable MACT Floor be determined. EPA should gather this data and then propose separate emission standards relevant to the unique characteristics of these periods.

Comment: The IB ICR did not require any testing during start-up, shutdown and malfunction events. Without emissions data during these periods, EPA has absolutely no factual basis for concluding that the best performing units can achieve the proposed MACT limits during these events. For example, operations during boiler start-ups are different than normal plant operations. Certain plant components must be started in a specific sequence in order to ensure that steady state operations can be achieved. During start-up not all pieces of control equipment will be operating at peak efficiency. NRECA believes work practices standards are far more appropriate during these periods. Similarly, for the same reasons, work practice standards are also more appropriate for shutdown and malfunction events.

If EPA insists, however, on setting emission limits for these periods of operation then the agency must obtain emission data during these periods of operation and properly analyze those data in order to set MACT emission limits.

Comment: Under the proposed rules, particulate matter would need to be continuously monitored. The EPA CEMS data does not indicate whether SSM conditions were present. Therefore, the validity of that data for determining the impact of SSM conditions is unknown. B&W recommends that the units that set the floor limits should be continuously monitored and tested during SSM conditions to verify the ability to meet a 30-day rolling average with SSM.

Comment: Based on the EPA's 2008 Combustion Survey there are 13,555 boilers/process heaters currently in operation at major sources in the United States. To evaluate continuous operation, EPA used CEMS data from only six (6) existing boilers, which is not sufficient to fully evaluate variable load considerations as well as startup, shutdown and malfunction concerns for continuous compliance for all source categories. This amounts to an evaluation of 0.04 percent of the sources to provide a representative limit for all sources.

Comment: Finally, EPA's analysis failed to properly address the variability of the data, as well as emissions associated with startup, shutdown and malfunction. Thus, EPA's proposed limits do not appropriately address the variability in emissions of various HAPs. In addition, EPA's proposed limits are unduly impacted by issues associated with the limits of detection. Fundamentally, numerical limits should be based on quantifiable and reproducible test results consistent with reliable source test methods that have well-established performance. Limits should not be based on tests and methods that raise issues of significant measurement and other uncertainties.

Comment: EPA's approach to addressing startup, shutdown, and malfunction (SSM) periods in the Proposed Boiler MACT is contrary to the statute's requirement that the standards established under section 112(d) be "achievable." See 42 U.S.C. § 7412(d)(2). Furthermore, EPA's claims that the MACT standards reflect startup and shutdown periods are not supported by the record. EPA needs to identify test data submissions that were performed during SSM and assess whether enough data exists to demonstrate that emissions during SSM are accounted for and are achievable. EPA should also set work practice standards for SSM events, since EPA did not correctly consider emissions from SSM events.

Comment: EPA makes a mistake with regard to its proposal not to set a separate standard for periods of startup, shutdown, and malfunction. On the one hand, EPA asserts that "[t]he standards we are proposing are daily or monthly averages ... [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." On the other hand, EPA uses short term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction.

To assure that startup, shutdown, and malfunction are appropriately accommodated, EPA must either assure that the data on which the standard is based include representative data from such periods or, alternatively, set a separate work practice standard to properly accommodate startup, shutdown, and malfunction.

Comment: Concerned about the potential for enforcement of operating parameter and opacity limits during periods of startup, shutdown, and in the event of equipment malfunction. When EPA finalized its rule in 2004 with enforceable operating parameters, it did so with a rule that also made clear that those limits did not apply during periods of "startup, shutdown, and malfunction." 40 C.F.R. § 63.7505(a), 69 Fed. Reg. at 55,254. EPA's current proposal contains no such exception, but instead would allow enforcement of deviations from operating parameters during these periods, when controls would not be expected to be operating at the same levels as during performance tests, and due solely to equipment malfunctions. In its proposed rule, EPA asserts that it has taken startup and shutdown periods into account by using continuous emissions monitoring system ("GEMS") data from best performing units that include periods of startup and shutdown, and by proposing use of "daily or monthly averages." Regarding malfunctions, EPA asserts that it would use a variety of information to determine an appropriate response to exceedance caused by equipment malfunction.

Comment: Exemption following new unit and major maintenance overhaul starts

There needs to be an exemption in the rule for each SSM period associated with commissioning of new units and with a restart following a major maintenance overhaul of the unit. Emissions will be higher during these periods while equipment and controls are brought into service for the first time. This is part of new/overhauled equipment commissioning and needs to be recognized by the compliance limits.

Comment: While this issue may be "hidden" for compounds that are stack tested (assuming stack tests never occur during startup or shutdown), this issue is very obvious for pollutants that are continuously monitored. Even with a 30-day averaging period, the monthly CO average PPM values would be affected by including startup and shutdown events on a PPM corrected basis.

Additionally, we have a concern that if a standard includes startup and shutdown events, an agency could require stack testing during startup and shutdown events to ensure compliance under worst-case operating conditions.

Comment: EPA has not appropriately accounted for startup and shutdown emissions. While EPA makes the simplistic statement that boilers do not normally startup and shutdown more than once per day, they have not accounted for the fact that the startup and shutdown process is not like turning a light switch on and off — such processes on boilers can take several hours, with safety being a predominant concern in the practices employed.

1. Control devices may not be capable of normal operation during periods of startup and shutdown, meaning monitored parameters would not be within ranges established during performance testing.

2. Ranges established during performance testing for parametric monitors are based on maximum normal operations, which differ substantially from startup and shutdown processes.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: NREGA believes EPA's assertions regarding startup and shutdown are inapplicable to control device operating parameter limits, which are based on 12-hour averages (not daily or monthly averages) established during performance test (not based on GEMS data that include startup and shutdown). Even a daily block average, as proposed for opacity, does not provide sufficient protection if the unit does not startup or shutdown at exactly midnight, since there might not be sufficient data under normal operating conditions to compensate for the startup or shutdown period. In short, believes EPA has not made sufficient allowance in its rules for periods of startup and shutdown. To the contrary, EPA has proposed to require sources to establish control device operating parameter levels that are dependent upon load during periods of "maximum normal operating load," and then maintain those levels during periods other than maximum normal operating load, including startup and shutdown. Thinks EPA's proposal is unreasonable and the agency must address these periods by allowing sources to identify alternative parameters or by establishing simple work practice standards for these periods.

Comment: EPA's approach to addressing SSM periods in the Proposed Boiler MACT is contrary to the statute's requirement that the standards established under section 112(d) be "achievable." See 42 U.S.C. § 7412(d)(2). Furthermore, EPA's claims that the MACT standards reflect startup and shutdown periods are not supported by the record.

To address the decision in Sierra Club v. EPA, 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010), which vacated the exemption in 40 C.F.R. § 63.6(f)(1) and (h)(1) for SSM periods, EPA proposes emissions standards in the MACT for industrial boilers and process heaters that apply at all times, including periods of SSM. EPA claims in the preamble that startup and shutdown periods were taken into consideration when setting the MACT standards. See Proposed Boiler MACT Rule at 32,012-13. According to the preamble, continuous emissions monitoring data from the best performing units, which include startup and shutdown periods, are used to set the floor levels in the proposed rule. See id. at 32,013. EPA further notes that startup and shutdown are part of "routine operations" and are therefore "already addressed" in the MACT standards. See id.

With regard to malfunctions, however, EPA states that these periods should not be viewed as a "distinct operating mode," and thus, emissions from these periods do not need to be factored into developing the MACT floor levels. See id. Moreover, EPA states that even if malfunctions were to be considered a distinct operating mode, it would be "impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters"

given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration. Id.
When setting standards in the early 1990's under CAA 112(d), EPA used its New Source Performance Standards (NSPS) program as a model. The section 112 standards were acknowledged by EPA to be "essentially equivalent to [section 111] performance standards" and that "unpredicted and reasonably unavoidable failures of air pollution control systems" would occur. 58 Fed.Reg. 42,760, 42,777 (Aug. 11, 1993). To address this situation, EPA adopted a similar exemption to the one in the NSPS Program for SSM events and imposed a "general duty" to minimize emissions. Thus, EPA acknowledged, as early as 1993, that SSM events are not appropriate for inclusion in a MACT standard and that an alternative approach should be used to address these situations. While the D.C. Circuit has ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112, and so section 112(h) "work practices" or "operational" standards are available in certain limited situations. See Sierra Club v. EPA, 551 F.3d at 1028.

The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing NSPS under section 111 of the CAA, Portland Cement Ass'n v. Ruckelshaus, 486 F.2d 375, 398 (D.C. Cir. 1973), the court acknowledged that "'startup' and 'upset' conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." Id. at 399. Furthermore, in National Lime Ass'n v. EPA, 627 F.2d 416 (D.C. Cir. 1980), the court noted that "a uniform standard must be capable of being met under most adverse conditions which can reasonably be expected to recur." Id. at 431 n.46. The D.C. Circuit acknowledged this same principle almost 20 years later when reviewing emission standards for new sources in the medical waste incinerator rule under section 129 in Sierra Club v. EPA, 167 F.3d 658 (D.C. Cir. 1999). In that case, while the court did not find the record sufficient to support EPA's approach for new sources, the D.C. Circuit did not object to a standard-setting approach which would account for the performance of technology under the "worst reasonably foreseeable circumstances." See id. at 665. Furthermore, the D.C. Circuit reiterated the principle in National Lime that "where a statute requires that a standard be 'achievable,' it must be achievable 'under the most adverse circumstances which can reasonably be expected to recur.'" Id. at 665 (citing National Lime Ass'n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980)).

EPA's MACT floor-setting approach in the Proposed Boiler MACT ignores these longstanding principles and mischaracterizes the role startup and shutdown data plays (or rather, does not play, as the case is here) in EPA's floor-setting process. As noted above, EPA claims that the agency considered startup and shutdown periods when setting the floors because CEMS data, relied on by EPA in "establishing the standards," included data from those periods. See Proposed Boiler MACT Rule at 32,012. Despite this claim, however, EPA does not rely on the CEMs data when setting the floors for boilers and process heaters. To the contrary, as indicated by the ERG memorandum in the docket, EPA uses test run data collected through the ICR phase II testing process, which reflect normal (often steady state) operating conditions, to set the proposed floors. See Memorandum from A. Singelton, ERG, to J. Eddinger, U.S. EPA, MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National

Emission Standards for Hazardous Air Pollutants – Major Source at 3 (April 2010). Thus, according to EPA's own docket materials, the data used to set the proposed floors fail to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Furthermore, as the ERG memorandum makes abundantly clear, EPA's approach does not make use of the CEMs data (with the startup and shutdown information) in its variability analysis where it would be the most helpful in reflecting real world fluctuations in emissions. Id. Given the absence of startup and shutdown emissions information from the test run data relied on by EPA to set the proposed standards and the difficulty of collecting data from such brief operation periods, it is appropriate for EPA to set work practices for these events for boilers and process heaters. As noted earlier, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . ." CAA § 112(h)(1); 42 U.S.C. § 7412(h)(1). Gathering data from startup and shutdown periods would be challenging given the brief nature of these periods as well as the need to define the exact time period for what is considered "startup" and/or "shutdown." Moreover, the definition of "not feasible to prescribe or enforce an emission standard" is defined in the CAA as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." CAA § 112(h)(2); 42 U.S.C. § 7412(h)(2). Startup and shutdown episodes fit with this definition and would justify the agency setting work practices to address emissions during these periods. Furthermore, a work practices approach for these periods would be in keeping with the statute's requirement that MACT standards be "achievable" as well as with the requirement that a MACT standard apply at all times.

A work practices approach for these periods also would be consistent with EPA's recently promulgated MACT standards for compression ignition reciprocating internal combustion engines (CI-RICE). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, Final Rule, 75 Fed.Reg. 9648 (Mar. 3, 2010). Based on comments received from stakeholders, EPA finalized work practice standards for startup because the agency determined that it was "not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations." Id. at 9656. According to EPA, applicable test methods that would be needed to measure during these events "do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods." Id. at 9665. Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. See id. Startup and shutdown periods for boilers encounter similar testing challenges and costs.

Comment Excerpt Number: 40

Comment: EPA's preamble assertions regarding startup and shutdown are inapplicable to control device operating parameter limits, which are based on 12-hour averages (not daily or monthly averages) established during performance test (not based on CEMS data that include startup and shutdown). Even a daily block average, as proposed for opacity, does not provide sufficient protection if the unit does not startup or shutdown at exactly midnight, since there might not be sufficient data under normal operating conditions to compensate for the startup or shutdown period. In short, EPA has made absolutely no allowance in its rules for periods of startup and shutdown. To the contrary, EPA has proposed to require sources to establish control device operating parameter levels that are dependent upon load during periods of "maximum normal operating load," and then maintain those levels during periods other than maximum normal operating load, including startup and shutdown. EPA's proposal is patently unreasonable. EPA must address these periods in some other manner, for example by establishing simple work practice standards in lieu of operating parameters.

Comment: With respect to malfunctions, as noted earlier, EPA argues in the preamble to the Proposed Boiler MACT that these periods should not be considered a "distinct operating mode" and uses this to justify not factoring these emissions into the proposed MACT standards. Considering that EPA's proposed MACT standards are supposed to apply at all times, the implication is that periods of malfunction also are covered by the MACT standards that apply during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable."

Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should set work practice requirements to address periods of malfunctions as well. As noted above, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . ." Similar to startup and shutdown, malfunctions fit with the situations described in the definition of "not feasible to prescribe or enforce an emission standard" as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. As noted earlier, EPA acknowledges in the preamble to the Proposed Boiler Rule that it is "impracticable" to take periods of malfunctions into account when setting emissions standards given the "myriad different types of malfunctions that can occur across all sources in the category" and that "malfunctions can vary in frequency, degree, and duration, further complicating" the standard setting process. 75 Fed.Reg. at 32,013. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

Comment: EPA's promise to address periods of equipment malfunction by considering other information before enforcing exceedances of operating limits also provide little comfort, especially given the risk of citizen suits. Although UARG appreciates EPA's proposal to make clear that "deviations" of operating limits are not necessarily violations, nothing in EPA's proposal would prevent EPA, a state, or a plaintiff in a citizen suit from simply determining in their "discretion" that any particular exceedance constitutes a violation. Proposed § 63.7575. MACT standards are technology-based standards and must recognize that even the best performing technology occasionally fails.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: If EPA Adopts Numeric Emissions Limitations, the Final Rule Must Include a Separate Standard for Periods of Startup and Shutdown

The Proposed Rule does not include a separate standard for startup and shutdown. This is a fundamental problem that, if not corrected, will cause the final standards to be unachievable by even well designed and operated boilers. As a result, EPA must include a separate standard for startup and shutdown in the final rule.

EPA's emissions database provides continuous emissions monitoring system (CEMS) data from several of the better performing sources. Contrary to EPA's assertion in the preamble, these data show that daily average emissions should be expected to vary considerably on a day-to-day basis and that the variability spans the proposed levels of the standards. While it is difficult to discern the reasons for this variability based on the information provided in the database, there is little doubt that startups and shutdowns significantly contribute to the variable emissions performance of these units. Thus, the data indicate that EPA needs to include express accommodation for startups and shutdowns.

Second, basic scientific and engineering principles support the need for a separate standard for startup and shutdown. Particularly for CO emissions, combustion conditions will not be optimum during startup periods due to the generally low firing rate and the fact that the firing rate will be ramped up over the startup period. Thus, a significant period of non-optimum firing conditions will result in CO emissions performance – even on a daily average basis – that will be markedly different than performance during normal operations. EPA’s failure to acknowledge these basic technical and engineering principles renders the proposed standards arbitrary.

For these reasons, we believe that a separate standard for startup and shutdown is needed and is amply justified. We suggest that a work practice standard is most appropriate due to the lack of relevant data and the fact that an emission testing during startup is not technically and economically practicable. If EPA decides that a numeric standard is needed, the Agency should rely on the available long term data from the better performing boilers to establish a standard with a reasonably long averaging time (such as a 30-day rolling average), rather than the proposed 24-hour averaging time.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Because EPA's proposed standard provides no exception for periods of startup, shutdown, or malfunction, the standard must be achievable under those conditions as well as the normal operating conditions under which stack tests are conducted. According to EPA's preamble discussion, EPA intends to address startup and shutdown by using daily or monthly averages and by establishing standards using CEMS data that include periods of startup and shutdown. 75 Fed. Reg. at 32,013. Again, since EPA has not identified any PM CEMS data used to establish the proposed standards, let alone PM CEMS data that include periods of startup and shutdown, UARG assumes that EPA intends to rely solely on averaging time to compensate for the higher emission rates expected during those periods. However, EPA has no basis to assume that PM CEMS data collected during periods of startup and shutdown will be accurate even within the permissible error bands described above, because PM CEMS are not correlated to Method 5 under those conditions (nor could they be given the difficulty of performing EPA test methods under such non-steady state conditions).

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: In addition, during Start-up, Shutdown, Malfunction (SSM) periods, boilers and process heaters operate under conditions that are likely to generate unavoidable increases in CO emissions. These conditions are driven by safety considerations (e.g., ensuring sufficient air flow to avoid explosive fuel-rich scenarios), operational concerns (e.g., gradually warming up the equipment in order to prevent thermal damage), and warranty requirements (e.g., equipment vendors require gradual warm-up as a warranty condition). Thus, setting the proposed inappropriately low CO emissions limit will encourage quick start-up and shutdown of equipment in order avoid exceedances of limit. EPA should not promulgate a rule that promotes such unsafe and improper operation of boilers and process heaters.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA's approach to addressing startup, shutdown, and malfunction (SSM) periods in the Proposed Boiler MACT is contrary to the statute's requirement that the standards established under section 112(d) be "achievable." See 42 U.S.C. § 7412(d)(2). Furthermore, EPA's claims that the MACT standards reflect startup and shutdown periods are not supported by the record.

To address the decision in Sierra Club v. EPA, 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010), which vacated the exemption in 40 C.F.R. § 63.6(f)(1) and (h)(1) for SSM periods, EPA proposes emissions standards in the MACT for industrial boilers and process heaters that apply at all times, including periods of SSM. EPA claims in the preamble that startup and shutdown periods were taken into consideration when setting the MACT standards. See Proposed Boiler MACT Rule at 32,012-13. According to the preamble, continuous emissions monitoring data from the best performing units, which include startup and shutdown periods, are used to set the floor levels in the proposed rule. See id. at 32,013. EPA further notes that startup and shutdown are part of "routine operations" and are therefore "already addressed" in the MACT standards. See id.

With regard to malfunctions, however, EPA states that these periods should not be viewed as a "distinct operating mode," and thus, emissions from these periods do not need to be factored into developing the MACT floor levels. See id. Moreover, EPA states that even if malfunctions were to be considered a distinct operating mode, it would be "impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters" given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration. Id.

When setting standards in the early 1990's under CAA 112(d), EPA used its New Source Performance Standards (NSPS) program as a model. The section 112 standards were acknowledged by EPA to be "essentially equivalent to [section 111] performance standards" and that "unpredicted and reasonably unavoidable failures of air pollution control systems" would occur. 58 Fed. Reg. 42,760, 42,777 (Aug. 11, 1993). To address this situation, EPA adopted a similar exemption to the one in the NSPS Program for SSM events and imposed a "general duty" to minimize emissions. Thus, EPA acknowledged, as early as 1993, that SSM events are not appropriate for inclusion in a MACT standard and that an alternative approach should be used to address these situations. While the D.C. Circuit has ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112, and so section 112(h) "work practices" or "operational" standards are available in certain limited situations. See Sierra Club v. EPA, 551 F.3d at 1028.

The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing NSPS under section 111 of the CAA, Portland Cement Ass'n v. Ruckelshaus, 486 F.2d 375, 398 (D.C. Cir. 1973), the court acknowledged that "'startup' and 'upset' conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." Id. at 399. Furthermore, in National Lime Ass'n v. EPA, 627 F.2d 416 (D.C. Cir. 1980), the court noted that "a uniform standard must be capable of being met under most adverse conditions which can reasonably be expected to recur." Id. at 431 n.46. The D.C. Circuit acknowledged this same principle almost 20 years later when reviewing emission standards for new sources in the medical waste incinerator rule under section 129 in Sierra Club v. EPA, 167 F.3d 658 (D.C. Cir. 1999). In that case, while the court did not find the record sufficient to support EPA's approach for new sources, the D.C. Circuit did not object to a standard-setting approach which would account for the performance of technology under the "worst reasonably foreseeable circumstances." See id. at 665. Furthermore, the D.C. Circuit reiterated the principle in National Lime that "where a statute requires that a standard be 'achievable,' it must be achievable 'under the most adverse circumstances which can reasonably be expected to recur.'" Id. at 665 (citing National Lime Ass'n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980)).

Comment: EPA's MACT floor-setting approach in the Proposed Boiler MACT ignores these longstanding principles and mischaracterizes the role startup and shutdown data plays (or rather, does not play, as the case is here) in EPA's floor-setting process. As noted above, EPA claims that the agency considered startup and shutdown periods when setting the floors because CEMS data, relied on by EPA in "establishing the standards," included data from those periods. See Proposed Boiler MACT Rule at 32,012. This representation is a serious misstatement of the Agency's record. EPA does not rely on the CEMs data when setting the floors for boilers and process heaters. To the contrary, as indicated by the ERG memorandum in the docket, EPA uses test run data collected through the ICR phase II testing process, which reflect normal (often steady state) operating conditions, to set the proposed floors. See Memorandum from A. Singelton, ERG, to J. Eddinger, U.S. EPA, MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 3 (April 2010). Thus, according to EPA's own docket materials, the data used to set the proposed floors fail to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Furthermore, as the ERG memorandum makes abundantly clear, EPA's approach does not make use of the CEMs data (with the startup and shutdown information) in its variability analysis where it would be the most helpful in reflecting real world fluctuations in emissions. Id.

Comment: Given the absence of startup and shutdown emissions information from the test run data relied on by EPA to set the proposed standards and the difficulty of collecting data from such brief operation periods, it is appropriate for EPA to set work practices for these events for boilers and process heaters. As noted earlier, section 112(h) allows EPA to set work practice standards for situations where “it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . .” CAA § 112(h)(1); 42 U.S.C. § 7412(h)(1). Gathering data from startup and shutdown periods would be challenging given the brief nature of these periods as well as the need to define the exact time period for what is considered “startup” and/or “shutdown.” Moreover, the definition of “not feasible to prescribe or enforce an emission standard” is defined in the CAA as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” CAA § 112(h)(2); 42 U.S.C. § 7412(h)(2). Startup and shutdown episodes fit with this definition and would justify the agency setting work practices to address emissions during these periods. Furthermore, a work practices approach for these periods would be in keeping with the statute’s requirement that MACT standards be “achievable” as well as with the requirement that a MACT standard apply at all times.

A work practices approach for these periods also would be consistent with EPA’s recently promulgated MACT standards for compression ignition reciprocating internal combustion engines (CI-RICE). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, Final Rule, 75 Fed. Reg. 9648 (Mar. 3, 2010). Based on comments received from stakeholders, EPA finalized work practice standards for startup because the agency determined that it was “not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations.” Id. at 9656. According to EPA, applicable test methods that would be needed to measure during these events “do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods.” Id. at 9665. Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. See id. Startup and shutdown periods for boilers present similar levels of testing challenges and costs.

Comment: Malfunctions, EPA argues in the preamble to the Proposed Boiler MACT that these periods should not be considered a "distinct operating mode" and uses this to justify not factoring these emissions into the proposed MACT standards. Considering that EPA's proposed MACT standards are supposed to apply at all times, the implication is that periods of malfunction also are covered by the MACT standards that apply during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable."

Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should set work practice requirements to address periods of malfunctions as well. As noted above, section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . ." Similar to startup and shutdown, malfunctions fit with the situations described in the definition of "not feasible to prescribe or enforce an emission standard" as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. As noted earlier, EPA acknowledges in the preamble to the Proposed Boiler Rule that it is "impracticable" to take periods of malfunctions into account when setting emissions standards given the "myriad different types of malfunctions that can occur across all sources in the category" and that "malfunctions can vary in frequency, degree, and duration, further complicating" the standard setting process. Proposed Boiler MACT Rule at 32,013. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

Comment: EPA's underlying database contains no data for start-up, shutdown or malfunction events — yet these periods of operation are not excluded from compliance obligations. This is yet another example of how the Agency has failed to show that the proposed emission limits are achievable. Another critical issue with respect to the achievability of the proposed emission limits is the absence of an exemption for start-up, shutdown and malfunction events. Clearly, the data upon which EPA characterized the best performing similar source and the best performing 12 percent of existing sources contain no start-up, shutdown or malfunction events. EPA has absolutely no technical basis to claim the proposed emission limits are achievable -- as is required by law.[42 U.S.C. §7412(d)(1).] If EPA insists on not exempting start-up, shutdown and malfunction events, the Agency must deal with emissions that occur during such events.

The simplest approach is to suggest that EPA obtain data representative of start-up, shutdown and malfunction events, include such data in a proper analysis and choose a numerical emission limits that can be achieved in practice. However, the data collection approach may not be realistic in every case. For example, manual test methods, such as EPA Method 5 for PM, are designed to be used under steady state conditions. Trying to conduct a Method 5 test during a boiler start-up may neither be practical nor accurate. Likewise, PM CEMS may not be the answer because a PM CEMS must be correlated with manual test data to be accurate. Thus, in cases where data collection during start-up, shutdown and malfunction events is not feasible, EPA should set work practice standards. However, EPA cannot simply ignore emission variability during start-up, shutdown and malfunction events and pretend that the emission limits are achievable without addressing this fundamental issue.

Comment: EPA SHOULD DEVELOP STARTUP, SHUTDOWN, AND MALFUNCTION STANDARDS. ACC is very concerned about the lack of separate start-up, shutdown, and malfunction (SSM) emission standards or work practice standards within the proposed rule. EPA indicates in the preamble that it considered these periods in establishing the proposed standards. The following reasons are cited for not including such periods.

EPA's approach to SSM periods in this proposal is contrary to the statute's requirement that the standards established under section 112(d)(2) be "achievable." Furthermore, EPA's claims that the proposed standards reflect consideration of emissions during startup and shutdown periods are not supported by the record.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 98

Comment: To address the decision in Sierra Club v. EPA [551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010).], which vacated the exemption in 40 C.F.R. section 63.6(f)(1) and (h)(1) for SSM periods, EPA proposes emissions standards in this rule that apply at all times, including periods of SSM. As noted above, EPA claims that startup and shutdown periods were taken into consideration when setting the MACT standards and that CEMS data from the best performing units, which include startup and shutdown periods, was used to set the floor levels in the proposed rule. EPA further notes that startup and shutdown are part of "routine operations" and are therefore "already addressed" in the standards. .

When setting standards in the early 1990's under section 112(d), EPA used its NSPS program as a model. The section 112 standards were acknowledged by EPA to be "essentially equivalent to [section 111] performance standards" and that "unpredicted and reasonably unavoidable failures of air pollution control systems" would occur. [58 Fed. Reg. 42760, 42777 (Aug. 11, 1993).] To address this situation, EPA adopted a similar exemption to the one in the NSPS Program for SSM events and imposed an overarching "general duty" to minimize emissions. Thus, EPA acknowledged, as early as 1993, that SSM events are not appropriate for inclusion in a MACT standard and that an alternative approach should be used to address these situations. While the D.C. Circuit has ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112, and so section 112(h) "work practices" or "operational" standards are available in certain limited situations.[See Sierra Club v. EPA, 551 F.3d at 1028.]

The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing performance standards under section 111 of the CAA,[Portland Cement Ass"n v. Ruckelshaus, 486 F.2d 375, 398 (D.C. Cir. 1973).] the court acknowledged that "'startup" and "upset" conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated."[Id at 399.] Furthermore, in National Lime Ass"n v. EPA, [627 F.2d 416 (D.C. Cir. 1980).] the court noted that "a uniform standard must be capable of being met under most adverse conditions which can reasonably be expected to recur." [Id at 431 n.46.] The D.C. Circuit acknowledged this same principle almost twenty years later when reviewing emission standards for new sources in the medical waste incinerator rule under CAA section 129. [Sierra Club v EPA, 167 F.3d 658 (D.C. Cir. 1999).] In that case, while the court did not find the record sufficient to support EPA's approach for new sources, the D.C. Circuit did not object to a standard-setting approach which would account for the performance of technology under the "worst reasonably foreseeable circumstances."[Id at 665.] Furthermore, the D.C. Circuit reiterated the principle in Ntil Li that "where a statute requires that a standard be "achievable," it must be achievable "under the most adverse circumstances which can reasonably be expected to recur.""[Id at 665 (citing National Lime Ass"n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980)).]

EPA's MACT floor-setting approach in this proposed rule ignores these longstanding principles and mischaracterizes the role startup and shutdown data plays (or rather, does t play, as the case is here) in EPA's floor-setting process. As noted above, EPA claims that it considered startup and shutdown periods when setting the floors because CEMS data, relied on by EPA in "establishing the standards," included data from those periods. However, EPA does not rely on the CEMS data when setting the floors for boilers and process heaters. To the contrary, as shown in the floor memo, EPA uses test run data collected through the Phase II ICR testing process, which reflect normal (often steady state) operating conditions, to set the proposed floors. Thus, according to EPA's own docket materials, the data used to set the proposed floors fail to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Furthermore, as the floor memo makes abundantly clear, EPA's approach does not make use of the CEMS data (with the startup and shutdown information) in its variability analysis where it would be the most helpful in reflecting real world fluctuations in emissions.[EPA-HQ-OAR-2002-0058-0815].

Comment: The data shown below [see submittal for Figure 8 and Figure 9] is a subset of the data in the docket. These excerpts reflect start-up and shutdown CO data from two facilities: a coal fired unit and a wood fired unit. Both data sets provide EPA data during periods of start-up and shutdown. While the absolute values are different in both cases, the data indicate that carbon monoxide levels are up to twenty times greater during such periods. This is due to the influence of oxygen levels, i.e., when fuel values are low, as during periods of start-up and shutdown, oxygen levels are higher, making the corrected pollutant concentrations much higher. Further, as noted in the data set, the raw pollutant levels are elevated due to unstable combustion.

If EPA had examined these data in some detail, it would have recognized two important aspects of the startup and shutdown periods. First, during startup periods, the oxygen content of the flue gas is generally very high, resulting in high calculated concentrations of pollutants, when they are corrected to 3 or 7 percent oxygen. Second, during shutdown periods, solid fuel boilers continue to emit pollutants for some time while the fuel feed rate has gone to zero. Thus, during those periods the pollutant emission rates when measured in terms of the heat input rate would contain a zero in the denominator and would equal infinity. Combining emissions during shutdown periods with all operating periods would mean an emission limit of infinity. Based on this ridiculous outcome, we recommend that EPA exclude periods of startup and shutdown from its numerical standards and replace them with work practice standards aimed at minimizing pollutant emissions.

It is apparent that EPA did not consider this data when it established the proposed standards. In each of the cases presented above, the proposed standards would have been exceeded during a 30 day period based simply on a start-up and shutdown event. We believe that EPA should strongly reconsider this information before finalizing a standard that "considers" startup and shutdown events.

Comment Excerpt Number: 100

Comment: Data is not available in the data sets provided by EPA, but the following hypothetical example demonstrates the effect. The methodology to be used to demonstrate compliance with the particulate limits would be as follows:

Equation 19-1 of 40 CFR 60 Appendix A Method 19:

$E = Cd * Fd * 20.9/(20.9 – O2d)$

Where

Cd = Pollutant Concentration (lb/dscf).
Fd = F Factor (dscf/MMBTU). Assume wood firing F = 9240 O2d = Oxygen Concentration (%).

Using the above equation the following set of results can be calculated: [see submittal for unnumbered table.]

In such situations it is very likely sources will exceed the proposed standards for several hours until combustion is stabilized. In this example, a start-up period of just a few hours would exceed the standard of 0.02 lb/MMBTU. Similar examples could be generated for the other pollutants regulated in the proposal, given adequate time to comment. It is important to note that in the above scenario, the actual concentration emitted is held constant. In real situations this may not be the case.

Comment: Institutional, commercial and industrial boilers, like their larger Electric Generating Unit (EGU) analogs, require an extended period of startup during which most, if not all, equipment in the boiler and pollution control systems are not operating in their normal condition.

This extended startup period, typically several hours, is required due to equipment integrity concerns, limitations of the technologies, or safety concerns:

Equipment Integrity – A Fabric Filter (FF) cannot be put into service until the flue gas temperature is above the dew point. This requires that all heat transfer surfaces, ducts and flues from the combustion zone to the FF inlet be warmed up from ambient temperatures to dew point temperature (which varies by fuel type and fuel constituents, but is typically in excess of 140 degrees F / 60 degrees C and can be up to 280 degrees F/138 degrees C). It takes a considerable amount of time, typically several hours for larger units, to warm up this considerable mass of refractory and steel: waterwall tubes, superheater tubes, reheater tubes, economizer tubes, casings, turning vanes, air preheaters, ducts and inlet plenums. During this warm-up period, the FF cannot be put into service without risking catastrophic failure of the bags and intensive corrosion damage to the FF. Similarly, electrostatic precipitators (ESPs) must typically warm-up to be effective. Premature starting of this equipment will lead to short term stability problems that could result in unsafe actions and longer term degradation of ESP performance due to fouling, increased chances of wire damage or increased corrosion within the chambers. These situations limit a unit's ability to control Particulate Matter and Mercury during the several hours of startup.

Limitations of the Technology – Units equipped with a Spray Dryer Absorber (SDA) for acid gas removal are limited in the amount of reagent slurry that can be injected into the flue gas during startup. The slurry federate is limited due to the nature of the technology by the amount of moisture the flue gas can evaporate. This in turn requires that a minimum temperature be achieved by the flue gas before the slurry feed rate can be initiated, and imposes a lengthy period of time during which the slurry federate is significantly limited until all the upstream heat transfer surface and ductwork has been warmed up. As such, SDA cannot remove Hydrogen Chloride in significant quantities for several hours after the unit is first fired.

Safety Concerns – Reductions in the amount of time required to warm the boiler system up could be realized by increasing the ramp-rate of adding fuel to the unit. In theory, a boiler could be brought from first flame to full load in a matter of minutes, but decreasing the warm-up period from what the Original Equipment Manufacturer (OEM) recommends risks severe refractory damage and excessive metallurgical stresses due to rapid changes in temperature and wide variances in temperatures across boiler and duct parts. Immediate failures could occur if inconsistent heating caused tears or ruptures in support steel or heat transfer surfaces, posing considerable risk to personnel in the plant. Failure rates would also increase due to the considerable stresses introduced by rapid heating and cooling cycles, yielding failures at unpredictable times (steady state operation or future startups or shutdowns). For this reason, OEM recommendations for startup times are closely followed across industry.

Comment: ACC applauds the fact that EPA is allowing the use of emissions averaging and common stack monitoring in its proposal, although ACC provides specific comments on how the emissions averaging provisions can be improved elsewhere in this document. However, in the context of periods of startup and shutdown, ACC does not see how either of these provisions would be particularly useful. For example, if a site has two boilers, one of which routinely achieves levels below the standard and one of which slightly above the standard, but averaged are able to achieve the required standard. It is unclear to ACC how these standards could be met during periods when the boiler with the lower emission rate is not operating.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Given the limited carbon monoxide data and total absence of startup and shutdown emissions information for other pollutants from the test run data relied on by EPA to set the proposed standards and the infeasibility, if not impossibility, of collecting data from such brief operation periods for other pollutants, it is appropriate for EPA to set work practices for these events for boilers and process heaters. As noted earlier, section 112(h) allows EPA to set work practice standards for situations where it is not feasible to prescribe or enforce an emission standard. Gathering data for other pollutants from startup and shutdown periods would be nearly impossible given the brief nature of these periods, as well as the need to define the exact time period for what is considered ‘startup" and/or ‘shutdown,", and the fact that most reference methods would not perform well during these periods. Moreover, the definition of "not feasible to prescribe or enforce an emission standard" is defined in section 112(h) as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Startup, shutdown, and malfunction events fit perfectly within this definition for the reasons outlined above and would justify EPA establishing work practices to address emissions during these periods. Furthermore, a work practices approach for these periods would be in keeping with the statute’s requirement that MACT standards be "achievable" as well as with the underlying requirement that a MACT standard apply at all times.

As discussed earlier in these comments, a work practices approach for these periods also would be consistent with EPA’s recently promulgated standards for CI-RICE. Based on comments received from stakeholders, EPA finalized work practice standards for startup because the Agency determined that it was "not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations."[RICE Rule, 75 Fed. Reg. at 9656.] According to EPA, applicable test methods that would be needed to measure during these events "do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods."[Id. at 9665.] Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. [Id.] Startup and shutdown periods for boilers encounter similar testing challenges and costs.

Comment: With regard to malfunctions, EPA states in this proposed rule that these periods should not be viewed as a "distinct operating mode," and thus, emissions from these periods do not need to be factored into developing the floor levels. Moreover, EPA states that even if malfunctions were to be considered a distinct operating mode, it would be "impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters" given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration.

Considering that these proposed standards are supposed to apply at all times, during a malfunction the source would have to meet a standard established for emissions during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable." It also makes no sense for EPA to state that a malfunction is not a "distinct" operating mode but standards based on normal operating mode shall apply during a malfunction. Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should establish work practice requirements to address periods of malfunctions as well. Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. EPA acknowledges in this proposed rule that it is "impracticable" to take periods of malfunctions into account when setting emissions standards given the "myriad different types of malfunctions that can occur across all sources in the category" and that "malfunctions can vary in frequency, degree, and duration, further complicating" the standard setting process.[75 Fed. Reg. at 32013.] Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

Comment: ACC believes that it is appropriate for EPA to revisit this issue. ACC suggests that EPA propose work practice standards that would allow sources a certain time period for start-up, shutdown and malfunction events and as long as certain procedures are followed, then compliance would be met. Those work practice standards should require the development and implementation of an emissions minimization plan that will result in (a) minimizing emissions during such events that would exceed otherwise applicable emission limitations, and (b) for malfunctions that will cause the unit to exceed otherwise applicable emission limitations, promptly identifying and implementing measures to remedy the malfunction.

While there may be some instances where standard work practices can be identified for a type of source, ACC cautions that overly prescriptive and non-facility-specific requirements can actually be counterproductive, restricting the operators" flexibility in a way that hampers their ability to troubleshoot or respond to an event, or that compromises safety. The plan itself should not be incorporated into the Title V permit. The plan should be an evolving document, and it would be very cumbersome to have to seek a modification of the Title V permit every time the plan changed. If the details of the emissions minimization plan had to be made part of the permit, facilities would tend to make the plans less specific and therefore probably less useful. For the same reason, these plans should be maintained at the facility rather than being required to be submitted to the permitting authority with the Title V application or otherwise.

Alternatively, EPA could establish a threshold of exceedances either a number or percentage of operating times that could occur during a quarterly or six month period before a violation occurs.

This methodology is consistent with other MACT standards such as 40 CFR 63 Subparts S and MM.

Comment: Sources Will Not Be Able To Meet Some OPLs On Startup or Shutdown. As stated in the comments related to appropriate averaging times and related to startup and shutdown, many types of control equipment are not in full operational mode while a boiler is starting up or shutting down. Therefore, OPLs will not always be feasible to meet during startup or shutdown. EPA should instead establish work practices for startup and shutdown periods, in lieu of requiring operating parameter limits to be met.

Comment: Startup, Shutdown, Malfunction: The proposed standards do not adequately account for periods of startup, shutdown or malfunction because the EPA uses short-term performance test results to set emission limits, not the results of long-term Continuous Emission Monitoring. EPA must recognize that boilers do not run at a "steady state" condition; therefore the proposed limits cannot be met while boilers are starting up and shutting down.

Comment: Important Improvements Made by EPA in the Proposed Rules
Start up, shut down, and malfunction rules: The previous boiler MACT proposal and the prior solid waste incinerator rules contained exceptions for otherwise applicable emissions limits during "periods of startup, shutdown and malfunction." [Footnote: 75 Fed. Reg. at 32,012] In accordance with the D.C. Circuit's opinion in Sierra Club v. EPA (2008), [Footnote: 551 F.3d 1019 (DC Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265 (2010).] the current proposed rules do not contain any such exemptions, and the proposed standards would apply to regulated sources at all times. [Footnote: 75 Fed. Reg. at 32,012.]

In addition to the legal reasons contained in the D.C. Circuit's opinion, this change is also justified on policy grounds. As the proposed rule notes, startup and shutdown are entirely predictable events and can be included in the general emissions standard by EPA. [Footnote: 75 Fed. Reg. at 32,013.] By contrast, malfunction events should be entirely unpredictable and, as the preamble for the Major Source Proposal notes, the best performing sources should not be malfunctioning at all. [Footnote: 75 Fed. Reg. at 32,013.]

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: I want to underscore the importance of eliminating the malfunction exemptions. On the other rules, the exemption allows chemical plants, refineries and other major facilities to violate their emissions standards over and over and over again without any accountability.
And as you know, I have personally fought a very long battle with the Agency on the startup/shutdown of malfunction provisions. These provisions at large sources of combustion like refineries, chemical manufacturing facilities, power plants, cement kilns can double or triple emissions.
And it's very difficult with these startup/shutdown and malfunction get out of jail free cards for local citizen groups to have any kind of enforcement hook to reduce those emissions. It makes a mockery of the toxic release inventory. It makes a mockery of the permits to allow these start-up and shutdown malfunction exemptions. And so I actually copied pretty good case law from the D.C. Circuit on this and we want to make sure that these startup/shutdown malfunction provisions are closed.

Comment: We definitely appreciate the EPA's efforts to control polluting boilers and process heaters at large facilities. In particular, we support the exclusion of exemptions for malfunctions, finally ending a loophole which allows emission sources to smother communities with pollution in blatant disregard of standards. We urge the EPA to reject calls to reopen this and other exemptions that undermine the health standards of this new regulation.

Comment: Especially important to us is EPA's decision to eliminate the outrageous malfunction exemption. In other words, the exemptions of our chemical plants, refineries, and other major polluters to violate the emission standards and blanket our communities in toxic pollution over and over again without any accountability.
Closing that loophole means that these facilities will have to run their boilers and process heaters responsibly. We know that powerful industry lobbyists are lining up to oppose this rule. They want loopholes and exemptions. They want the rules weakened and delayed, but these rules will prevent 4,800 unnecessary deaths every year and will save billions of dollars in costs. Lisa Jackson, do not cave in to industrial pressure. Make these rules stronger, not weaker, and we issue them without delay -- please issue them without delay.

Comment: Especially important to us is EPA's decision to eliminate the outrageous malfunction exemption. State's emissions data have made it clear that chemical plants, refineries, and other polluters violate their emissions standards routinely during so-called malfunction events. During these events they blanket neighboring communities in toxic pollution, making people sick and forcing them to miss work, miss school, and seek medical help. These events also increase the likelihood that the people in these communities will suffer from cancer, birth defects, and other catastrophic adverse health effects. The malfunction loophole has already been held unlawful by a Federal Appeals Court. Closing it will bring an end to the abuse by ensuring that polluters can be held accountable when they violate emission standards.

One great example of that is in Corpus Christi, Texas, where it has been documented that some of the major releases –- you can actually document by the major releases the next day the number of children in emergency rooms. And you can also document the time lost by their parents from work by the number of children who are in emergency rooms and the fugitive releases and other releases in the communities in the evenings.

Document Control Number: EPA-HQ-OAR-2002-0058-2530.1
Comment Excerpt Number: 1

Comment: For all boilers and process heaters, EPA is proposing that facilities should maintain daily records of fuel use that demonstrate that they have burned no materials that are considered solid waste. See §63.7550. EPA is also proposing to require certification of the following statement on the compliance reports: ‘No secondary materials that are solid waste were combusted in any affected unit.” The requirement to certify that no solid waste was burned may not be feasible, as explained below.

CPA agrees with AF&PA’s separate comments on EPA’s waste identification rule explain that various secondary material streams that clearly constitute legitimate fuels will contain “incidental” materials that cannot practically be screened out, make no discernable difference to the environmental characteristics of the fuel stream, and either have fuel value or do not detract from fuel value. In those comments, AF&PA urged EPA, following long-established RCRA practice, to allow the burning of such incidental materials as part of the fuel stream that will inevitably contain them.

In addition, there is really no humanly possible way to prevent any discarded materials from finding their way into legitimate fuel streams. Someone at some time will throw oily rags, or waste paper, or a bandage, or earplugs, onto a bark pile or similar fuel storage facility, or a storm may blow small amounts of these materials onto a fuel storage pile.

Beyond such unavoidable events, there are also cases where it would make sense in terms of overall social policy to deliberately burn incidental materials in boilers without turning them into CISWI units. For example, the residues from cleaning up spills of non-hazardous materials, such as oil and hydraulic fluid, are often simply burned. So, on occasion, are scrubber residuals.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for a response to de minimis quantities of non-hazardous secondary materials.

Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 26

Comment: (15) Proposed § 63.7545(e), which describes what must be included in the Notification of Compliance, requires further revision. This proposed provision references (e)(1) through (9) but there is no (8) and (9) included in the proposal. In addition, this proposed requirement is not appropriate for natural gas-fired boilers and should be clarified to exclude boilers that do not have emission limits. Compliance certification for remaining MACT requirements (i.e. annual tune-up) for natural gas-fired boilers and process heaters can be addressed by the existing Title V Compliance Certifications.

Response: EPA has revised the Notification of Compliance requirements to address the cross reference issue identified by the commenter. The EPA disagrees with the comment that natural gas-fired boilers should be excluded as these boilers are still subject to some of the requirements in the Notification of compliance status. Regarding Title V Compliance Certifications, the rule allow sources to submit any notification or report including those required by Title V certifications and reports.

Comment Excerpt Number: 28

Comment: EPA declined to address de minimis quantities of non-hazardous secondary materials in the proposed solid waste definition rule [75 FR 31844]. We believe this is not practical or realistic, and places facilities at compliance risk even for accidental or inadvertent presence of miscellaneous materials in a stockpile or storage bin of biomass fuel. EPA should address an exclusion for de minimis materials combusted in boilers and process heaters.

Response: There is no de minimis level of allowable solid waste combustion. Sources are expected to take measures to prevent the combustion of solid waste materials to the maximum extent practicable. While sources may believe it is beneficial to deliberately combust small amounts of various solid waste materials, the rule does not allow for such deliberate combustion of solid waste materials, and, based on recent court decisions, cannot allow such.

Comment Excerpt Number: 64

Comment: EPA should clarify the notification required by § 63.7545(f) that this notification is not required when burning other gaseous fuels.

This notification is required when there is a natural gas curtailment or supply interruption. By definition, a gas-fired unit (either natural gas, refinery gas, or Gas 2) can burn fuel oil up to 48 hours without being classified as a "unit designed to burn oil". However, the wording of the notification requirement could be interpreted to be triggered when a Gas 1 unit needs to burn Gas 2 (other fuels can contribute up to 10 percent heat input annually to a Gas 1 unit). EPA should clarify the wording of this notification provision to clarify it applies to either Gas 1 or Gas 2 units that need to burn liquid fuels during a curtailment of natural gas supply interruption.

Response: The 10 percent allowance for other fuels in a Gas 1 unit is no longer in the rule. The notification is required if any other fuels are combusted with the noted exceptions for 48 hours or periodic testing, or for periods of curtailment or gas supply emergencies.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group
Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 65

Comment: Proposed § 63.7545(f) – This provision requires notification within 48 hours when burning backup fuel during a curtailment event. This notification does not make sense given that backup fuels are allowed by existing permits. Burning a backup fuel is not like burning a new fuel. It would be more appropriate for EPA to require identification of the use of backup fuels as part of the semi-annual compliance report for Title V. Another consideration is that sources would need more than 48 hours to provide notification, which would have to be certified by a responsible official. Furthermore, more than 48 hours may be needed in states that require electronic submittals through internet-based applications. For these reasons this requirement is unnecessary and should be deleted from the final rule.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2894.1, excerpt 6 for a response to alternative fuel use notifications.

Commenter Name: Timothy Hunt

Comment Excerpt Number: 304

Comment: AF&PA's comments on EPA's waste identification rule explain that various secondary material streams that clearly constitute legitimate fuels will contain "incidental" materials that cannot practically be screened out, make no discernable difference to the environmental characteristics of the fuel stream, and either have fuel value or do not detract from fuel value. In those comments, AF&PA urges EPA, following long-established RCRA practice, to allow the burning of such incidental materials as part of the fuel stream that will inevitably contain them.
In addition, there is really no humanly possible way to prevent any discarded materials from finding their way into legitimate fuel streams. Someone at some time will throw oily rags, or waste paper, or a bandage, or earplugs, onto a bark pile or similar fuel storage facility, or a storm may blow small amounts of these materials onto a fuel storage pile.
Beyond such unavoidable events, there are also cases where it would make sense in terms of overall social policy to deliberately burn incidental materials in boilers without turning them into CISWI units. For example, the residues from cleaning up spills of non-hazardous materials, such as oil and hydraulic fluid, are often simply burned. So, on occasion, are scrubber residuals.

Law enforcement agencies sometimes ask facilities with boilers to help them dispose of contraband marijuana by burning it. This can be particularly true in rural areas where other disposal options are limited. AF&PA sees no reason to use CISWI to ban such useful practices. Instead, EPA should amend its CISWI rule and its Boiler rules to provide that facilities could burn incidental amounts of waste without being classified as a CISWI unit. AF&PA believes such exclusion would be entirely proper. There is a presumption in favor of agency power to establish such an exclusion. That presumption tracks back to Judge Leventhal's statement many years ago that unless Congress had been "extraordinarily rigid", agencies had inherent power to exclude from regulation cases where the gain from regulation would be of "trivial or no value". Alabama Power Co. v. Costle, 636 F.2d. 323, 360-61 (D.C. Cir. 1979).
It is true that the CISWI opinion said, 489 F.3d at 1260, that when Congress defined a "solid waste incineration unit" as a unit that burned "any" solid waste, see § CAA §129(g)(1), it meant "any" to mean "any". However, the court did not address the question of whether EPA could establish an exclusion from any such literal reading that would allow incidental amounts of solid waste to be burned with legitimate fuels. The Clean Air Act case on which the court chiefly relied also stated most strongly that "any" meant "any" and then expressly said this did not preclude a de minimis exclusion. See New York v. EPA, 443 F.3d. 880, 888 (D.C. Cir. 2006).

Moreover, the environmental petitioners in CISWI also expressly left this point open. See Brief for Environmental Petitioners at 6 (stating that "Environmental Petitioners express no view on whether EPA might be able to demonstrate on remand that [excluding a unit that sometimes burns 1% solid waste from CISWI] meets this Court's standards for establishing de minimis administrative exclusions.")

Indeed, EPA has already in effect established such exclusions in its CISWI rules. For example, the medical incinerator rules do not cover household waste (see 40 CFR §60.51c definition of "medical infectious waste"). Similarly, the proposed CISWI rule itself does not literally follow the statute. While the statute calls for EPA to establish emission limits for "any facility" that combusts solid waste, EPA's proposal would apply only to any "commercial or industrial facility" that burns such material, see proposed §60.2265, 75 Fed. Reg. 31983.

Of course EPA acted entirely properly in thus proposing to exclude home stoves and fireplaces from regulation. Excluding from regulation de minimis amounts of materials burned in larger units would be no less proper.

EPA's approach to RCRA regulation leads to the same result. Since RCRA regulation began EPA has allowed the handling and disposal of small amounts even of hazardous waste outside the RCRA system, since such an exclusion does not pose any environmental danger, while attempting to regulate such small amounts would lead to many regulatory absurdities. See generally 40 CFR 261.5 (authorizing the disposal of small quantities even of hazardous waste outside the hazardous waste regulatory system.)

For all these reasons, AF&PA urges EPA to allow non-CISWI combustion units to burn up to 1% by weight non-hazardous solid waste without becoming CISWI units.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for a response to de minimis quantities of non-hazardous secondary materials.

Comment: Notifications {Sec 63.7545}

Whirlpool Corporation believes the 48 hour notification time limit for Gas 1 units temporarily switched over to an alternate fuel is burdensome. Potentially, a weekend "switch over" may not be relayed to responsible parties until after the 48 hour period. Unlike a spill event, this information is not time critical. We requests that the notification be extended to a minimum of 72 hours.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2894.1, excerpt 6 for a response to alternative fuel use notifications.

Comment: In §63.7505(d), we suggest changing the first sentence to begin with "If you demonstrate compliance with a CEMS or operating limits, you must develop a site-specific monitoring plan..." A liquid fire boiler less than 100 MMBtu/hr heat input may be able to meet the emission limits without air pollution control equipment and would be too small to require CEMS. These facilities should not have any required continuous monitoring systems and therefore no need for a site-specific monitoring plan.

Response: EPA has revised the §63.7505(d) requirement in response to this comment and others like it.

Commenter Name: Melvin E. Keener

Comment: As proposed, EPA requires reporting of test results within 60 days of completing each performance test. It will be difficult to get certain results back and reviewed within that time frame, and close to impossible for dioxin samples without paying a premium. EPA's current methods have the following hold times for Method 23: 21 days to extraction and 40 days from extraction to analysis. Recently, many laboratories have struggled to meet these holding times simply because of the large number of samples to be analyzed. Adding the test results from all the units in this rule will further strain the system and may cause even longer delays. CRWI suggests that this requirement be changed to 90 days.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2880.1, excerpt 67 for a response to the request for a data submission extension.

Commenter Name: Leonard W. Sandridge

Document Control Number: EPA-HQ-OAR-2002-0058-2769.1
Comment Excerpt Number: 29

Comment: The definition for unit designed to burn gas 1 (NG/RG) subcategory includes "any boiler or process heater that burns at least 90% natural gas and/or refinery gas on a heat input basis on an annual average. Unit designed to burn oil subcategory definition states that "gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year are not included in this definition."

We have 17 boilers that are designed to burn natural gas and distillate oil, many of which can meet the definitions above by only using oil during gas curtailments or restricting the annual heat input to
less than 10%. How do we document that our gas/oil boilers fall under the definition of the gas 1 subcategory? Do we need permit limits to cap the oil use to qualify? Do we submit fuel consumption data with the semi-annual report to document qualification as a gas 1 boiler? We support the latter method.

Response: EPA has revised the definition for units designed to burn gas 1 in response to this comment and others like it. Units subject to an emission limit are required to keep records of fuel usage.

Comment: (g) You must report the results of performance tests (stack test and fuel analyses) within 60 days after the completion of the performance tests.

EPA should amend paragraph (g) to provide boiler owners with 120 days to report performance test results. Due to the complexity of EPA Method 23 for dioxin/furan, there presently exists a backlog problem at many labs to complete the analytical portion of the method, sometimes extending well beyond 60 days. In addition, as a result of this rulemaking there will be a significant increase in the volume of testing and analytical work conducted nation-wide for industrial boilers and process heaters.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2880.1, excerpt 67 for a response to the request for a data submission extension.

Comment: The proposed rule states that if you operate a natural gas-fired boiler or process heater that is subject to this subpart, and you intend to use a fuel other than natural gas or equivalent to fire the affected unit, you must submit a notification of alternative fuel use within 48 hours of the declaration of a period of natural gas curtailment or supply interruption.

We believe that it is EPA's intent that the 48-hour notification only needs to be submitted when the natural gas supply is curtailed or interrupted. The language could be misinterpreted to require this notification when alternative fuels are fired in a gas-fired unit during maintenance checks and readiness testing. Maintenance checks and readiness testing are routine, planned events recommended by the Federal, State or local government, the manufacturer, the vendor, or the insurance company associated with the boiler or process heater. Implementation of the test procedures require advance planning before tests are conducted; therefore, the notification submittal is unnecessary.

Revise 63.7545(f) as follows to ensure the rule allows testing without notification of alternative liquid fuel for a natural gas-fired boiler or process heater for the purpose of maintenance checks and readiness testing.
(f) If you operate a natural gas:fired boiler or process heater that is subject to this subpart, and you intend to use a fuel other than natural gas or equivalent to fire the affected unit during a period of natural gas curtailment or supply interruption, as defined in §63.7575, you must submit a notification of alternative fuel use within 48 hours of the declaration of a period of natural gas curtailment or supply interruption, ; . The notification must
include the information specified in paragraphs (f)(1) through (5) of this section.

Response: EPA agrees with the commenter and has clarified the rule requirements accordingly. For additional information on alternative fuel use notifications refer to DCN EPA-HQ-OAR-2002-0058-2894.1, excerpt 6.

Comment: Notifications
Under the Proposed Rule, an owner or operator would be required to submit notifications based on the schedule set forth in proposed § 63.7545. 75 FR 32060. The Proposed Rule is not clear whether another initial notice is required for units that filed under the prior Subpart DDDDD. EPA should clarify whether an additional notice is required for units that filed under the prior Subpart DDDD.

Response: All sources must submit the initial notification requirements for this rule, regardless of whether or not the source previously submitted an initial notification under the vacated standard. Based on responses to the survey EPA identified that many sources have switched to area sources or shutdown certain boilers since the vacated rule was finalized and the Agency needs an updated listing of affected sources.

Comment: Proposed 63.7521 requires, for fuel testing, development and submission a detailed site-specific fuel analysis plan to the EPA Administrator for review and approval 60 days before testing. Since testing is required monthly, it appears this plan is required monthly, which makes no sense. Furthermore, we do not see any justification for requiring such a plan for gas- or liquid-fired boilers or process heaters, unless alternate test methods are to be used. For gas and liquid fuels we believe all that should be required, if rule methodologies are used, is a record of what fuels will be sampled and where the sample will be taken.

Recommendation: Revise 63.7521 as suggested above. Replace the requirement for developing and submitting a fuel testing plan for gas- and liquid-fired units to a recordkeeping requirement.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2769.1, excerpt 24 for a response to fuel analysis plan submittals.

Comment: 7. 63.7530(e) requires You must submit the energy assessment report, along with a signed certification that the assessment is an accurate depiction of your facility, while 63.7545(g)(2) specifies that the NCS must contain a certification that This facility has had an energy assessment performed according to 63.7530(e). 63.7545(g)(2) does not require submission of the energy assessment with the NCS.

Per the requirements of Table 3, the energy assessment report will be massive and will be crammed with proprietary facility detail that must be maintained as confidential under the Confidential Business Information provisions of the CAA. Thus, submitting the detailed report serves no purpose and only greatly increases the burden imposed on regulatory agencies. Proposed 63.7530(e) should not be finalized.

Recommendation: If the energy assessment requirements are finalized, finalize proposed 63.7545(g)(2) and drop proposed 63.7530(e).

Response: EPA has dropped the requirement to submit a copy of the energy assessment in 63.7530(e) in response to comment; this is consistent with the notification requirements in 63.7545(e)(8)(ii). The certification that was in 63.7550(g)(ii) is now in 63.7545(e)(8)(ii).

Comment: Proposed 63.7545(e) specifies If you are required to conduct an initial compliance demonstration as specified in 63.7530(a), you must submit a Notification of Compliance Status according to 63.9(h)(2)(ii). For each initial compliance demonstration, you must submit the Notification of Compliance Status, including all performance test results and fuel analyses, before the close of business on the 60th day following the completion of the performance test and/or other initial compliance demonstrations according to 63.10(d)(2). The word each in the second sentence and the 60 day time requirement seems to require a separate NCS for every performance test, of which there will be a great many under this rule. To be efficient, it has been common practice historically to allow grouping of all initial performance test results and all other required NCS information into one report, due within 180 days after the compliance date of a part 63 rule.

Recommendation: Allow sources to submit one NCS report, 60 days after completion of all required initial compliance demonstrations or 180 days after the compliance date, whichever is earlier.

Response: EPA has revised the § 63.7545(e) in response to comments to clarify that the Notification of Compliance Status is for the affected source and shall be submitted 60 days after the compliance demonstration is completed for the whole affected source (i.e., after all performance stack tests are completed).

Comment: Proposed 63.7545(e)(1) specifies that the NCS contain "A description of the affected source(s) including identification of which subcategory the source is in, the design capacity of the source, a description of the add-on controls used on the source, description of the fuel(s) burned, including whether the fuel(s) were determined by you or EPA through a petition process to be a non-waste under 40 CFR 241.3, whether the fuel(s) were processed from discarded non-hazardous secondary materials within the meaning of 40 CFR 241.3, and justification for the selection of fuel(s) burned during the performance test." We have the following comments on this requirement.

The requirement should ask for the information on a boiler and process heater basis, not an affected source basis, since the existing affected source is a collection of boilers and process heaters within a subcategory.

Presumably the "capacity" information desired is the design heat duty (firing rate), not the steam generation or process fluid capacity, of the unit. This item should be revised to make that clear.

Recommendation: Clarify 63.7545(e)(1) as recommended above.

Response: EPA has revised § 63.7545(e)(1) in response to the comment and changed "source" to "unit" and "design capacity" to be "design heat input capacity."

Comment: Proposed 63.7550 specifies that semi-annual compliance reports be submitted 31 days after the end of each calendar half. Thirty-one days is inadequate time to gather, review and tabulate all of the data for all of the sources at a major site. Under this proposal, there is a massive amount of information that must be manually developed and tabulated. For instance, obtaining Hg and Cl- fuel analysis information from the outside laboratories that typically perform these analyses for the large number of units at a typical major source will require the better part of the 31 days. Furthermore, the report must provide information on performance tests performed during the reporting period and EPA normally and rightfully provides 60 days to report performance test results.

Recommendation: Require compliance reports 60 days after the end of the compliance period, rather than 30 days after.

Response: EPA has not revised the semi-annual compliance report submittal dates specified in § 63.7550. These dates are consistent with the General Provisions in 40 CFR 63 Subpart A.

Comment: Proposed 63.7550(c)(4) requires submission in the compliance report of monthly fuel use data. Monthly fuel information for boilers and process heaters can be used to calculate proprietary process operating and production data. This will cause many sites to classify this data as Confidential Business Information. Furthermore, we see no reason why this information is needed. The continuing compliance monitoring provides assurance the emission limitations are being met, where there are emission limitations. For the Gas 1 category, work practice deviations are reported and there are no emission limits that involve knowing how much fuel was used. There is no obvious need for this information and, given its sensitive nature it should be removed from this report.

Recommendations: Do not finalize the requirement to report monthly fuel use data.

Response: EPA disagrees with removing this reporting requirement. This data can be used for verification of heat input, which is used in different calculations. If the item is considered as sensitive, the facility can submit the data as confidential business information if they so choose.

Comment: Proposed 63.7550(e) establishes reporting requirements if there is a deviation from an emission limit, operating limit, or monitoring requirement occurring at an affected source where you are using a CMS to comply with that emission limit or operating limit. However, the specific requirements seem to be a mix of deviation associated information and general information. The required information should be limited to that associated with a deviation and the subparagraphs need clarification as follows. Requiring vast listings of information on every CMS at a source serves no purpose and only burdens the source and the reviewers.

63.7550(e)(2) requires reporting of “The date and time that each CMS was inoperative, except for zero (low-level) and high-level checks.” This should be clarified that only the information on the CMS associated with the deviation is required, not all CMS being used for compliance with this rule. Also, any planned maintenance or QA/QC outage covered by the applicable monitoring plan should not have to be reported, not just zero and high level checks. For instance, required calibrations and RATA tests should also be excused from reporting. Gathering such information serves no purpose.

63.7550(e)(3) requires reporting of “The date, time, and duration that each CMS was out of control, including the information in 63.8(c)(8).” Again, this should be limited to the CMS associated with the deviation. 63.8(c)(8) already requires reporting of out-ofcontrol periods for all CMS in the compliance report, so this paragraph should only be required for out-of-control periods associated with the deviation.

63.7550(e)(5) requires reporting “A summary of the total duration of the deviation during the reporting period and the total duration as a percent of the total source operating time during that reporting period.” However, (e)(4) already requires reporting the start and stop times of the deviation and (e)(6) requires reporting the % of operating time for which there are deviations. Thus, (e)(5) is both confusing as to what it requires, but also duplicative and thus it should be deleted.

63.7550(e)(7) requires reporting “A summary of the total duration of CMS downtime during the reporting period and the total duration of CMS downtime as a percent of the total source operating time during that reporting period.” Again this should be clarified that only the information on the CMS associated with the deviation is required, not all CMS being used for compliance with this rule. Since most CMS downtime is associated with required, planned routine maintenance and QA/QC activities a general tabulation provides no value and only imposes large burdens, given the large number of CMS that will be present at a major source.

Recommendation: Clarify and revise the deviation reporting requirements.

Response: The EPA disagrees with the commenter that § 63.7550(e) is duplicative are requires revision. The subparagraphs of § 63.7550(e) require that only deviations from an emission limit be reported. It should be noted that a continuous monitoring system deviations may not be associated with an emission limit deviations.

Comment: We also encourage EPA to add materials that EPA's definition of solid waste rule ultimately defines as wastes to the list of materials that that can constitute up to 30 percent of the heat input without the boiler being considered an incinerator. In the communities where our mills are located, the boilers serve an important function to the community as the means of choice for combusting materials that we have always considered fuels but that EPA is threatening to classify as wastes. For example, if the local police or federal authorities make a drug bust or cut down a marijuana farm, it is our boiler that they turn to for destruction of the illicit material. Landfilling several hundred pounds of marijuana is not an option, nor is shipping it to an incinerator hundreds of miles away. Similarly, wood products facilities are increasingly the option of choice for combustion of separated wood deriving from construction and demolition. If these materials are classified as solid wastes, it is critical that there be an exception to allow a small amount of our overall heat input to constitute these fuels.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for a response to de minimis quantities of non-hazardous secondary materials.

Comment: EPA should reduce or even eliminate reporting requirements for units/boilers only subject to work practice standards. Since these units are not required to install control devices, perform testing or are not subject to monitoring requirements, reporting would only consist of general facility information, fuel usage and a statement that tune-ups and energy assessment requirements were met. It is overly burdensome to require semiannual reports for this limited information.

Response: The EPA thanks the commenter for their input. The reporting requirements have modified in the final rule. For units subject to a work practice standard of an annual or biennial tune-up, the final rule requires the unit to report the date of the annual or biennial tune-up. We have reduced the compliance reporting frequency for these units to annually and biennially, respectively, instead of a standard semi-annual compliance schedule. We have added this requirement in a new paragraph 63.7550(c)(12). A report, not records, is consistent with the General Provisions in 40 CFR 63 Subpart A.

Comment: Table 2 Should Specify that the Averaging Time for HCl and Mercury is the Same as the Required Sampling Frequency. Section 63.7515(f) requires a monthly fuel analysis if compliance is demonstrated based on a fuel analysis for each type of fuel burned. Table 2 does not specify an averaging time for demonstrating compliance with the emission limits. Dow also supports revising the sampling frequency to semi-annual for HCl and mercury, and further comments that the averaging time should be on a semi-annual basis if this recommendation is adopted. Based on the proposed rule, at a minimum, the rule and Table 2 should state that a monthly average value should be used for HCl and mercury.

Response: The Hg and HCl limits are not based on an average. Compliance must be demonstrated each month, so no changes are needed to Tables 1 or 2 to include averaging times for Hg and HCl.

Comment: EPA Should Give Sources at Least 45-60 days to file semi-annual reports required by Subpart DDDDD
In 63.7550, EPA requires that sources file their semiannual reports by January 31st and July 31st of each year. The regulated community is inundated with numerous other reporting requirements during this same period. Duke Energy notes that in 63.7515 (g), EPA proposes to give sources 60 days to submit emission test reports. As a result, EPA should either directly allow, or allow local permitting agencies the flexibility to grant sources a minimum of 45 days, and preferably 60days to file their semi-annual reports.

Response: EPA disagrees with the commenter. The 30 day reporting requirements is consistent with the General Provisions in 40 CFR 63 Subpart A.

Comment: EPA should clarify that daily fuel use and operating hour records are not required for natural gas-fired units. The proposed rule is not clear regarding recordkeeping and reporting requirements for fuel use and operating hours, and preamble text and rule text are not consistent. As noted in the preamble, a reason for reporting daily fuel use is to ensure documentation of the type of fuel being combusted (e.g., solid waste is not combusted). When natural gas is the only fuel used, "fuel confirmation" can be achieved via much less onerous means than recording and reporting daily fuel use. For example, fuel type can be confirmed by the responsible company official in the compliance report. In addition, there are provisions in the rule that require notification if a fuel other than natural gas is used in a
natural gas-fired unit13. Fuel use records should not be required for natural gas-fired units complying with work practice standards, other than the annual work practice "tune up" record required in §63.7540(a)(10)(vi)(C) — i.e., "The type and amount of fuel used over the 12 months prior to the annual adjustment."
The rule text appears to limit these requirements to specific subcategories that include emission standards. §63.7550(c) contains compliance report information requirements and states in (c)(4): "The total fuel use by each affected source subject to an emission limit,..." [emphasis added]. Since natural gas-fired units are not subject to any emission limits, it appears that fuel use records or operating hour records are not required for natural gas-fired units in the rule text, but is not totally clear.
The final rule should clearly indicate that fuel use and operating hour recordkeeping and reporting requirements do not apply to natural gas-fired units subject to work practices other than the work practice requirement for an annual fuel use record. If EPA intends for more onerous requirements (e.g., daily records) for fuel use or operating hours for natural gas-fired units, the basis and associated burden for the requirement should be clearly documented and rationalized.

Response: The EPA disagrees with the commenter that the recordkeeping and reporting requirements for natural gas need clarification. Natural gas fired units are not subject to limits and do not need to keep fuel use records.

Commenter Name: Pamela F. Faggert

Comment Excerpt Number: 36

Comment: For work practice standards, schedule requirements for tune-ups are specified in 63.7515(e). Specifically, each annual tune-up must be conducted between 10 and 12 months after the previous tune-up. Similar timing for sources subject to biennial tune-ups is not addressed. EPA should revise 63.7515(e) to provide flexibility and address biennial tune-up timing.
In some cases, an operator may have cause to conduct a tune-up more frequently that required by the rule. It is unnecessary and counter-productive for the rule to specify a minimum time of 10 months on the periodicity for annual tune-ups, as long as the maximum allowed interval is met. If a source, for whatever reason (e.g., scheduling conflicts) wants to conduct an annual tune-up sooner than 10 months after the most recent tune-up, that flexibility should be allowed. Accordingly, the following text revisions to 63.7515(e) are provided to address this issue for both annual and biennial tune-ups, "(e) If you are required to meet an applicable work practice standard, you must conduct
performance tune-ups according to 63.7540(a)(10) or (11) 63.7520. Each annual tune-up must be conducted no later than 12 months after the previous tune-up. Each biennial tune-up must be conducted no later than 24 months after the previous tune-up."

Response: Rather than requiring tune-ups to be conducted between 10 and 12 months, the final requirement is that each annual tune-up must be no more than 13 months after the previous tune-up, and each biennial tune-up must be conducted no more than 25 months after the previous tune-up.

Comment: As is discussed in other sections of the rule, test results must be reported within 60 days of the completion of the test. Test results for some parameters may not even be available until weeks following the completion of testing. Sixty days does not provide sufficient time to properly review all data results (including requisite quality control and assurance), perform and review the calculations and conclusions resulting from the test, prepare and certify reports and submit results electronically or manually. Similar requirements under the HWC MACT (Subpart EEE) and other MACT standards allow for reporting 90 days following testing. In addition under Subpart EEE itself, there is a provision to request additional time to complete a report in case 90 days is not enough time. Thus, the owner/operator should be provided 90 days to submit the information to EPA's WebFire database on a voluntary basis, and should be allowed to seek additional time for extenuating circumstances.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2880.1, excerpt 67 for a response to the request for a data submission extension.

Comment: EPA Should Not Require 48 hour Notification for Burning an Alternate Fuel Due to a Period of Natural Gas Curtailment or Interruption. Section 63.7545(f) of EPA's proposed rule requires submission of a notification of alternative fuel use within 48 hours of the declaration of a period of natural gas curtailment or supply interruption. The subsection goes on to indicate curtailment and interruption are defined in a later subsection.

Reporting of the use of alternative fuel during natural gas curtailment or interruption should be included in the semiannual compliance report as opposed to the proposed 48 hour reporting requirement for the following reasons:

EPA provides no insight or justification in the preamble or otherwise for requiring this 48 hour notification. There is no indication of how or to whom the notification is to be made. There is no definition provided for either "curtailment" or "interruption". Reporting such events within 48 hours is an unnecessary and burdensome requirement.

Reporting the use of alternative fuel within 48 hours serves no purpose. EPA proposes neither any immediate use of the notification nor any value it provides. Gas interruptions can occur during periods of adverse weather or natural disaster which could make such rapid reporting problematic.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2894.1, excerpt 6 for a response to alternative fuel use notifications.

Comment: EPA Should Delete the Requirements in Section 63.7550(e) since Most of This Information will be Included in the Title V Semi-Annual Deviation Report. All sources that are subject to this rule are located at a major site for HAP emissions, and thus are subject to Title V Operating Permit requirements.

The majority of the information required to be reported in proposed Section 63.7550(e) will be captured by individual state semi-annual Title V Deviation Reports. Although the details of state reporting requirements may vary some from state to state, Dow comments that EPA should rely on information provided in the respective state semi-annual deviation reports instead of creating an additional and somewhat different set of requirements for the owner/operator to have to comply with. Thus, Dow comments that the requirements in section 63.7550(e) be deleted from the final rule and that EPA simply rely on information that is reported as part of state semi-annual Title V deviation reports. State agencies should also benefit from this approach as they don't have to review similar information submitted for each boiler/heater subject to this rule.

Response: The EPA has determined that no change in § 63.7550(e) is needed. The rule already allows sources to submit Title V Semi-Annual Deviation Reports to document a deviation in this subpart.

Comment: Notifications — section 63.7545

Section 63.7545(f) states that "If you operate a natural gas-fired boiler or process heater that is subject to this subpart, and you intend to use a fuel other than natural gas or equivalent to fire the affected unit, you must submit a notification of alternative fuel use within 48 hours of the declaration of a period of natural gas curtailment or supply interruption, as defined in section 63.7575."

PFI requests clarification and guidance on the following issues related to this section:

1. Whether such a notification would apply during each curtailment event or only once a facility has reached a point where such an event would begin to compromise their ability to operate under the Gas 1 subcategory, assuming that the heat input related to the use of alternative fuels during a period of natural gas curtailment must be accounted for in assessing compliance with that subcategory.

2. The intent and purpose of requiring facilities to make such a notification — A similar requirement exists under section 63.7550(g) of the final vacated rule (69 FR 55218), presumably due to comments received based on the proposed rule (68 FR 1660) since it was not included in that document. However, PFI was unable to locate any information in the preamble of the final vacated rule or in this proposed rule related to why it was added or its intent or purpose. PFI believes such a requirement would be burdensome on both facilities and regulators and believes that natural gas curtailment or supply interruption events could be adequately monitored and enforced through recordkeeping and compliance certifications.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2894.1, excerpt 6 for a response to alternative fuel use notifications. In addition, as clarification, the notification applies to each curtailment event.

Comment: EPA Should Have Minimized Facility Monitoring and Reporting Requirements

Several SERs noted that recordkeeping activities, as written in the vacated boiler MACT, would be especially challenging for small entities that do not have a dedicated environmental affairs department. The SERs advocated for the most efficient way to get reductions in HAP and requested that the Panel consider all available alternatives to reduce to a bare minimum any extraneous requirements that require a lot of paperwork that in the opinion of the SERs do not contribute to emission reductions.

Response: EPA must balance monitoring and reporting requirements with compliance assurance. EPA has determined that these requirements have been adequately minimized and are consistent with the General Provisions in 40 CFR 63 Subpart A.

If these materials are classified as solid wastes, it is critical that there be an exception to allow a small amount of our overall heat input to constitute these fuels.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for a response to de minimis quantities of non-hazardous secondary materials.

Comment: Remove Requirement for Notification of Alternative Fuel Use.
Proposed section 63.7545(f) requires that, for gas-fired boilers or process heaters, a notification of alternative fuel use be submitted within 48 hours of a declaration of natural gas curtailment or supply interruption. There does not appear to be an underlying purpose for submitting such notifications (e.g. there is no requirement that alternative fuels only be used during curtailment, and there is no requirement that curtailment events be limited in number or duration). Furthermore, proposed section 63.7540(a)(10)(vi)(C) would require recordkeeping of the types and amounts of fuel used in each boiler or process heater with a heat input capacity of 10 million BTU/hour or greater in the Gas1 (NG/RG) subcategory, which would assure compliance with the proposed requirement that such units not exceed 10 percent utilization of alternative fuels on a heat input basis on an annual average. Therefore, to minimize the administrative burden of the rule on both the sources and on the EPA/delegated authorities that would receive these notifications, this notification requirement should be removed from the rule.

Response: EPA disagrees that this notice is unnecessary. The notification requirement will allow EPA to ensure that only those units that qualify as Gas 1 units remain in the Gas 1 subcategory. Other commenters have noted that curtailments are an unlikely event, so the burden of this requirement should be minimal.

Comment: 63.7545(f): 48 hour notifications for natural gas fired units that are required to switch fuels due to natural gas curtailments is excessive. For these cases that are out of the control of the gas user, semi-annual reporting should be acceptable.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2894.1, excerpt 6 for a response to alternative fuel use notifications.

Comment: LPT supports EPA’s decision to consider wastewater treatment sludge a fuel under this MACT proposal. The ability to utilize this material for energy recovery is very important to the economic viability of our Company. In addition this decision is supportive of the Maine

DEP's goals for waste minimization and the licensing of beneficial uses for these materials including fuel use.

LPT does manage other materials generated on site by burning for energy recovery. These include oily solid waste, waste cardboard, chipped pallets, and spent charcoal from air purifying units. These materials are burned in small, essentially insignificant amounts. As the rule is written to remain a boiler it appears these materials will not be able to be burned as fuel unless they are specifically approved by EPA. Absent that approval these materials will have to be landfilled which is contrary to the goals of the DEP. EPA should consider an exemption based on heat input allowing the combustion of these types of materials. The threshold could be 0.5-1% on an annual basis.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for a response to de minimis quantities of non-hazardous secondary materials.

Comment: The proposed rule contains a significant number of documentation requirements. Many of these requirements duplicate existing documentation requirements. It is understood that the agency desires proper documentation for compliance with the new rule, however the rule needs to be evaluated for duplication of existing requirements. Reference should be made to the existing federal documentation requirements. Any state documentation requirements that exceed the federal can be ignored and allow the individual states to resolve their issues.

Response: The EPA has determined that no change in documentation requirements are needed. Reporting requirements for this rule can be merged with those already required under State permitting programs.

Comment: Some provisions also require approval in order to move forward. [In several places, EPA uses the phrase submit for "approval upon request." See proposed §§ 63.7505(d)(1) and 63.7522(g). It is not clear if EPA is referring to a source owner/operator's request for approval, or a regulatory authority's request for submission. EPA should revise these provisions to remove this ambiguous phrase.] Although the provisions generally establish a required time-frame for submittal, e.g., 60 days before the initial performance evaluation or compliance demonstration, the rules do not impose any deadline for a response by the Administrator, permitting authority, or regulatory authority. EPA should provide that timely submitted requests for approval are automatically approved after 30 days if no response is received.

Response: EPA is referring to the delegated authority's request for submittal. Those delegated authorities that request submittal of such plans are expected to act within a reasonable time since they initiated the request. No change has been made.

Comment: The data required to be included in a semi-annual compliance report is overly burdensome and requires the permittee to develop and submit more information than is relevant to self reporting of compliance conditions. The US EPA should consider reducing these self reporting burdens to the minimum necessary to determine compliance. The US EPA seems to have transitioned from not only requiring soures to self-report deviations, but must also report data from compliance calculations for HCL or Hg. You must submit notices of intent to perform stack testing (in addition to those required by 40 CFR 63 Subpart A), copies of test reports (in addition to those required by Subpart A), the data from CMS performance reports (presumably this information must also be submitted in the CMS performance reports required), descriptions of each source and CMS system as well as changes to that CMS. The amount of data and information required to be included the twice yearly report is not insignificant and the US EPA is apparently requiring significant amounts of information that is required to be submitted by Subpart A be submitted again.

Response: EPA has not revised the semi-annual compliance report data requirements. Much of the data reporting and notifications are the same as in General Provisions in 40 CFR 63 Subpart A, but are just repeated in the rule for clarity.

Comment: EPA should extend the date for completion of the energy assessment report.
In the proposed rule, at §63.7545(g)(2), EPA specifies that the energy assessment must be completed by the compliance deadline and noted in the notice of compliance status. The Agency should allow a reasonable time following the final compliance deadline because there are no compelling reasons for requiring such an early completion. Indeed, as discussed above, mill and corporate staff will be fully engaged with selecting, installing and starting up the extremely complex control equipment that will be required for meeting emission limitations imposed by this rulemaking in a very short timeframe. Then for the next eight months following the compliance deadline, the facilities will be conducting the required emission testing and preparing the detailed test reports and compliance status reports required by the MACT General Provisions (40 CFR Part 63 Subpart A). Therefore, EPA should allow 18 months following the deadline for submission of the compliance status report for completion of the energy assessment report.

Response: We disagree with the comment that the completion date for the energy assessment should be extended past the proposed compliance date. The requirement for conducting an energy assessment only applies to existing facilities. The date for an existing facility to achieve compliance is 3 years after publication of the final rule. Three years is the maximum compliance period allowed under section 112 of the Clean Air Act. We believe that 3 years is more than sufficient considering that an energy assessment can be conducted in a manner of a few days. In the final rule, we have revised the definition of an energy assessment to include the maximum length of time to conduct an energy assessment at a small (one day) and medium (3 days) boiler energy use facility.

Comment: Proposed § 63.7550(h) requires reporting of test data to EPA within 60 days after completion of the performance evaluation. 75 Fed. Reg. at 32,062. Section 63.7(g) (applicable under Table 10) states that a performance test is "completed" when the field sample collection is terminated. Although receiving the analytical results of performance tests within 60 days generally is not a problem, it could be a problem for some tests -- like Method 23 for D/F -- that require intense laboratory procedures and for which there may only be a limited number of qualified laboratories. UARG requests that EPA include a provision allowing additional time for submittal of the results of D/F tests, if necessary.

Response: The dioxin testing requirement is now a one-time test, and sources have ample time (three years) to plan their test so as not to miss the submittal date for the initial compliance test. However, EPA recognizes the potential for backlog of laboratories and test contractors that have the capabilities to collect and analyze dioxin data and, therefore, is extending the time period to 90 days.

Comment: INCIDENTAL USE OF NON-HAZARDOUS SOLID WASTE SHOULD BE PERMITTED. For all boilers and process heaters, EPA is proposing that facilities should maintain daily records of fuel use that demonstrate that they have burned no materials that are considered solid waste. See proposed section 63.7550. EPA is also proposing to require certification of the following statement on the compliance reports: ""No secondary materials that are solid waste were combusted in any affected unit." The requirement to certify that no solid waste was burned may not be feasible, as explained below.

Our comments on EPA’s waste identification rule explain that various secondary material streams that clearly constitute legitimate fuels will contain "incidental" materials that cannot practically be screened out, make no discernable difference to the environmental characteristics of the fuel stream, and either have fuel value or do not detract from fuel value. ACC urges EPA, following long-established RCRA practice, to allow the burning of such incidental materials as part of the fuel stream that will inevitably contain them.

It should be recognized that it is nearly impossible to prevent any discarded materials from finding their way into legitimate fuel streams. Someone at some time will throw oily rags, or waste paper, or a bandage, or earplugs, onto a bark or coal pile or similar fuel storage facility, or a storm may blow small amounts of these materials onto a fuel storage pile.

Beyond such unavoidable events, there are also cases where it would make sense in terms of overall social policy to deliberately burn incidental materials in boilers without turning them into CISWI units. For example, the residues from cleaning up spills of non-hazardous materials, such as oil and hydraulic fluid, are often simply burned. So, on occasion, are scrubber residuals.

On quite a different note, law enforcement agencies sometimes ask facilities with boilers to help them dispose of contraband marijuana by burning it. This can be particularly true in rural areas where other disposal options are limited. ACC sees no reason to use CISWI to ban such useful practices.

Instead, EPA should amend its CISWI rule and its Boiler rules to provide that facilities could burn incidental amounts of waste without being classified as a CISWI unit. ACC believes such exclusion would be entirely proper. There is a presumption in favor of agency power to establish such an exclusion. That presumption tracks back to Judge Leventhal's statement many years ago that unless Congress had been "extraordinarily rigid", agencies had inherent power to exclude from regulation cases where the gain from regulation would be of "trivial or no value".[Alabama Power Co. v. Costle, 636 F.2d. 323, 360-61 (D.C. Cir. 1979).]

In vacating the CISWI Definitions Rule, the D.C. Circuit Court stated that when Congress defined a 'solid waste incineration unit" as a unit that burned "any" solid waste, it meant "any" to mean "any". [NRDC v. EPA, 489 F.3d 1250, 1260 (D.C. Cir. 2007).] However, the court was not asked to address the question of whether EPA could establish an exclusion from any such literal reading that would allow incidental amounts of solid waste to be burned with legitimate fuels. The Clean Air Act case on which the court chiefly relied also stated most strongly that "any" meant "any" and then expressly said this did not preclude a de minimis exclusion. [See New York v. EPA, 443 F.3d. 880, 888 (D.C. Cir. 2006).] Moreover, the environmental petitioners in CISWI also expressly left this point open. [See NRDC v. EPA, 489 F.3d 1250 (D.C. Cir. 2007).]

Indeed, EPA has already in effect established such exclusions in its CISWI rules. For example, the medical incinerator rules do not cover household waste (see 40 CFR section 60.51c definition of "medical infectious waste"). Similarly, the proposed CISWI rule itself does not literally follow the statute. While the statute calls for EPA to establish emission limits for "any facility" that combusts solid waste, EPA's proposal would apply only to any "commercial or industrial facility" that burns such material.[75 Fed. Reg. at 31983, Proposed section 60.2265. Brief for Environmental Petitioners at 6 (stating that "Environmental Petitioners express no view on whether EPA might be able to demonstrate on remand that [excluding a unit that sometimes burns 1% solid waste from CISWI] meets this Court's standards for establishing de minimis administrative exclusions.")]

Of course EPA acted entirely properly in thus proposing to exclude home stoves and fireplaces from regulation. Excluding from regulation incidental amounts of materials burned in larger units would be no less proper.

EPA's approach to RCRA regulation leads to the same result. Since RCRA regulation began EPA has allowed the handling and disposal of small amounts even of hazardous waste outside the RCRA system, since such an exclusion does not pose any environmental danger, while attempting to regulate such small amounts would lead to many regulatory absurdities. See generally 40 CFR 261.5 (authorizing the disposal of small quantities even of hazardous waste outside the hazardous waste regulatory system.)

For all these reasons, ACC urges EPA to allow non-CISWI combustion units to burn incidental amounts (e.g., up to 1% by weight) of non-hazardous solid waste without becoming CISWI units. EPA should revise the recordkeeping and reporting requirements in this Boiler rule to accommodate incidental amounts of non-hazardous solid waste.

Response: Daily records are not required. This was an error in the preamble that has been removed. Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for additional information on de minimis quantities of non-hazardous secondary materials.

Records That Must Be Retained

Comment: Reduce bookkeeping requirements. DEP contracts for its fuel on a long-term basis and does not use any solid fuel. Accordingly, daily fuel records are not necessary to prove that solid fuels are not used. Similarly, the various notices required to conduct performance tests, establish compliance status, and to use alternative fuels, should be greatly simplified to reflect the operational needs and standards in operating wastewater treatment plants.

Response: We have modified the daily fuel use records to monthly basis in accordance with the commenter's request. The notifications in this rule are consistent with those listed in the general provisions, but we have reduced some bookkeeping requirements since proposal in order to reduce the burden to the extent possible.

Comment: In the proposed rule, EPA proposes that all boilers and process heater units maintain daily records of fuel use that demonstrate that a facility has burned no materials that are

considered solid waste. 75 Fed. Reg. at 32,015. This requirement requires facilities to prove a negative and should be reconsidered.
TFI requests that all natural gas-fired boilers and process heater units be exempt from this requirement, as these units are not configured to burn solid waste. If EPA does not exempt natural gas units from this requirement, TFI requests that EPA redefine this requirement so that facilities are required to maintain records of the specific days on which a unit burns materials that may be considered solid waste. If EPA does not redefine the requirement, TFI asks for some guidance on how a facility demonstrates that it has burned no solid waste materials on a given day.

Response: Daily records are not required. This was an error in the preamble that has been removed. Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for additional information on de minimis quantities of non-hazardous secondary materials.

Comment: Section 63.7540(a)(10)(vi)(C) of the proposed rule would require the owner/operator to record the amount of natural gas burned in each gas-fired metal processing furnace. Most of these furnaces do not currently have natural gas meters and the capital cost to install these meters will be $15,000 to $20,000 per furnace. For several Alcoa facilities, the cost to purchase and install natural gas meters would be in excess of $1,000,000, which does not include ongoing maintenance, calibration and data acquisition costs. Tracking natural gas consumed per furnace is not necessary for proper burner maintenance, and maintenance records from burner tune-ups and CO levels will provide the Agency adequate documentation to verify that annual tune-ups have been completed. Furthermore, data on the amount of natural gas used will not provide an indication of burner performance during any 12-month period. Higher or lower gas use during any 12-month period will only be a function of variability in furnace operation (cycle times, operating temperatures and load size) over the 12 months. The requirement to install gas meters and record amount of gas burned should therefore be deleted from the proposed rule.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2729.1, excerpt 21 for a response to concerns related to fuel use recordkeeping and individual gas meters.

Comment Excerpt Number: 6

Comment: We request that EPA revise its proposal to eliminate the requirement to record the amount of fuel consumed for boilers or process heaters that only use natural gas. As long as natural gas is the sole fuel consumed in a boiler or process heater, the amount of fuel consumed is irrelevant to the other requirements in the rule. Moreover, the installation of fuel meters or other fuel estimation methods would be overly burdensome without sufficient cost justification in terms of hazardous emissions reporting. An owner or operator should be permitted to report that only natural gas has been combusted in the affected source in lieu of reporting the amount of fuel consumed. A requirement to report the amount of natural gas consumed in those circumstances would only create a disincentive for boiler and process heaters to use clean-burning natural gas versus another fuel.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2729.1, excerpt 21 for a response to concerns related to fuel use recordkeeping and individual gas meters.

Commenter Name: Lisa Beal
Commenter Affiliation: Interstate Natural Gas Association of America
Document Control Number: EPA-HQ-OAR-2002-0058-2756.1
Comment Excerpt Number: 11

Comment: EPA should clarify that keeping records of daily fuel use and operating hours is not required for natural gas-fired units.

The proposed rule is not clear regarding recordkeeping and reporting requirements for fuel use and operating hours, and preamble text and rule text are not consistent. Fuel use and operating hour recordkeeping and reporting requirements should be clarified.

As noted in the preamble, a reason for reporting daily fuel use is to ensure documentation of the type of fuel being combusted (e.g., solid waste is not combusted). However, for natural gas-fired units in gas transmission systems, natural gas will be the only fuel used and "fuel confirmation" can be achieved via much less onerous means than recording and reporting daily fuel use. For example, fuel type can be confirmed by the responsible company official in the compliance report. In addition, there are provisions in the rule that require notification if a fuel other than natural gas is used in a natural gas-fired unit. Fuel use records should not be required for natural gas-fired units complying with work practice standards, other than the annual work practice "tune up" record required in §63.7540(a)(10)(vi)(C) – i.e., "The type and amount of fuel used over the 12 months prior to the annual adjustment."

The preamble indicates that fuel use and operating hour records are required for natural gas-fired units. For example, the preamble indicates:

"For all boilers and process heaters, we are proposing that you maintain daily records of fuel use that demonstrate that you have burned no materials that are considered solid waste."

We are proposing that you must keep the following records:

(4) Daily hours of operation by each source.” [75 FR 32015]

And,

“We are also requiring that you keep daily records of the total fuel use by each affected source, subject to an emission limit or work practice standard,...” [75 FR 32035]

However, the proposed regulations appear to limit these requirements to specific subcategories – e.g., the requirement for fuel use records applies to units that include emission standards. For example, §63.7550(c) indicates compliance report information requirements and includes the following in (c)(4):

“(4) The total fuel use by each affected source subject to an emission limit,...” [emphasis added] In addition, §63.7545(f) requires notification for natural gas-fired units that intend to use a different fuel:

“(f) If you operate a natural gas-fired boiler or process heater that is subject to this subpart, and you intend to use a fuel other than natural gas or equivalent to fire the affected unit, you must submit a notification of alternative fuel use within 48 hours of the declaration of a period of natural gas curtailment or supply interruption, as defined in § 63.7575. The notification must include the information specified in paragraphs (f)(1) through (5) of this section.”

Thus, the objective to ensure that only natural gas is used for natural gas-fired units is addressed. Daily fuel use records or operating hour records do not appear to be explicitly required for natural gas-fired units in the rule text, but the rule is not clear.

INGAA recommends that the final rule clearly indicate that fuel use and operating hour recordkeeping and reporting requirements do not apply to natural gas-fired units subject to work practices other than the work practice requirement for an annual fuel use record. Confusion caused by text cited above should be clarified. The final rule should clearly indicate that §63.7545(f) provides assurance on fuel type for natural gas-fired units and 63.7540(a)(10)(vi)(C) identifies the requirement for annual fuel use records for units subject to work practices. If EPA intends for more onerous requirements (e.g., daily records) for fuel use or operating hours for natural gas-fired units, the basis and associated burden for the requirement should be clearly documented and rationalized.

Response: The final rule requires, monthly fuel use records be kept. It should be noted that monthly records apply only to units subject to limits in Tables 1 or 2. Fuel use records also included as part of the annual or biennial tune-up requirement specified in 63.7540(a)(10)(vi)(C).

Comment: Requirement for Individual Gas Meters in § 63.7540(a)(10)(vi)(C) Is Unnecessarily Burdensome.

The proposed work practice requirement for natural gas-fired boilers and process heaters in § 63.7540(a)(10)(vi)(C) would require a source to include in the on-site annual report the "type and amount of fuel used over the 12 months to the annual adjustment." This proposed requirement is of concern to the Auto Group. Most facilities do not have individual gas meters for tracking the amount of fuel used on the smaller in-plant boilers and process heaters. In fact, EPA has allowed many companies to apportion natural gas fuel usage to boilers subject to the industrial boiler New Source Performance Standards (NSPS), Subpart Dc, or keep a record of the fuel delivered to the property during the calendar month. [Footnote: See 40 C.F.R. § 60.48c(g)(3).] In addition, new reporting requirements of GHG emissions also are accomplished on a facility-wide basis and utilize the billing data from the main meter for the facility (or group of facilities).

Installing separate meters would be incredibly expensive, especially for complex manufacturing sources that have numerous affected sources. For example, one company participating in the Auto Group has 12 boilers and process heaters at a single facility. With an individual meter costing between $10,000-15,000 to install, a facility would have a compliance cost range of $120,000-180,000 just for the individual gas meters alone. While auto companies already are tracking and reporting fuel use on a facility wide basis for Title V annual emission reports and other state regulatory requirements, this data is on total fuel use and not on a boiler/process heater-specific basis. EPA needs to further explain and justify why this burdensome requirement is necessary for all the natural gas units given that individual gas usage data would not provide any useful information and is not necessary to demonstrate that a tune-up has been properly performed.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2729.1, excerpt 21 for a response to concerns related to fuel use recordkeeping and individual gas meters.

Comment: Small Boilers - Tune-ups for boilers under 10 MMBtu
PSU has approximately 73 boilers on contiguous property that meet this definition. An existing Preventative Maintenance program and schedule already exists. Also, it is required that the type of fuel and annual fuel use for each boiler is recorded. For
natural gas, the meters are at the building-level or even a group of buildings, not at the unit. There is no way to distinguish between fuel use for the boiler and other equipment in the building. This could be significant for research buildings or residential buildings with laundry and food service equipment. Providing this data on a boiler-by boiler-basis will require the

installation of additional meters. Unit fuel type and total group fuel use is already required as part of the GHG Mandatory Reporting Rule. The tune-up and fuel use recordkeeping and annual report creation will be arduous for large institutional facilities with many units. HAP reductions for these units will be negligible compared to complying large units. Penn State recommends that EPA drop the boiler-by-boiler fuel use recordkeeping requirement.

Response: Based on other comments, the record of fuel type and use in 63.7540(a)(10)(vi)(C) was revised so that it only needs to be kept if the unit is physically and legally capable of using more than one fuel type. This would exclude many natural gas fired institutional boilers that do not have a back up fuel. In addition, EPA has added the following language so as not to require units that use a single gas meter to install additional meters: For multiple units with a single gas meter, record the total usage for all units subject to the tuneup requirement in lieu of a unit-by-unit record.

Comment: Reconcile Daily Versus Monthly Fuel Records

As prescribed in the preamble section G(6) (75 FR 32014), section G(7) (75 FR 32015), section K (75 FR 32033), and section N (75 FR 32035), daily records of fuel use are to be maintained by each affected source; however, only monthly records of fuel use are to be maintained in accordance with 63.7555(5)(d)(1). The EPA needs to clarify if affected sources are required to maintain daily or monthly records of fuel use. As the EPA has set precedent (EPA 4APT-ATMB letter to SCDHEC dated March 7, 2002) by stating monthly records of fuel use for units subject to 40 CR 60 Subpart Dc can be maintained for natural gas fired units as well as distillate oil fired units, we agree with this record keeping approach for these types of units. Daily records for other fuel subcategories may be more appropriate to determine compliance with emission limits, fuel analysis protocol, or work practice standards as outlined in the referenced preamble sections above.

Response: EPA has revised the final rule to require that affected sources maintain daily records of fuel use.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group

Comment Excerpt Number: 46

Comment: Proposed § 63.7555(d)(1), which requires monthly fuel usage records for all boilers and process heaters, is a problem since facilities do not have separate meters for every process heater and boiler. Many facilities have centralized gas meters and do not have separate metering of the small boilers and process heaters. It should be sufficient to demonstrate compliance by keeping records of the fuel type burned (i.e., landfill gas) and information concerning the design maximum heat input (i.e., mmBtu/hr). See the discussion above regarding separate metering.

Proposed § 63.7555(d)(4), which requires calculation of a HCl emission rate for each boiler and process heater, does not make sense where sources use gaseous fuels from a common distribution system since the gaseous fuel would be the same for each unit. See the discussion above regarding separate metering.

Proposed § 63.7555(d)(5), which requires calculation of a mercury emission rate for each boiler and process heater, also is ill-suited for sources using gaseous fuels from a common distribution system since the gaseous fuel would be the same for each unit.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2729.1, excerpt 21 for a response to concerns related to fuel use recordkeeping and individual gas meters.

Comment: Proposed § 63.7555 Subsection (d)(7), which requires that if a source operates a gaseous fuel unit that is subject to the emission limits specified in Table 1 or 2 to this subpart, and you intend to use a fuel other than natural gas or equivalent to fire the affected unit, you must keep records of the information required by the notification under § 63.7550, and records of the total hours per calendar year that liquid fuel is burned. If the other fuel is landfill gas (note that the fuel does not necessarily have to be a liquid fuel), then the only requirements should be related to the other fuel usage rates (e.g., cubic feet per month or gallons per month).

Response: EPA agrees with the commenter and has clarified the requirements accordingly. Section 63.7555(d)(7) has been deleted and a new paragraph added under 63.7555(h) with adjusted language. This adjusted language specifies record keeping for "other" gas usage, not just liquid fuels.

Comment: The requirement to install a continuous emission monitoring system (CEMS) for CO should only apply to units that are subject to a CO emissions limit.

We do not believe that EPA expects units that are not subject to a CO emissions limit to install a CO CEMS. The final rule should be clarified to prevent this situation.

Revise §63.7525(a) as follows:
"If your boiler or process heater has a heat input capacity of 100 MMBtu per hour or greater and is subject to a CO limit, you must install, operate, and maintain a continuous emission monitoring system for CO and oxygen according to the procedures in paragraphs (a)(1) through (6) of this section by the compliance date specified in § 63.7495. The CO and oxygen shall be monitored at the same location at the outlet of the boiler or process heater.

Response: EPA has revised the rule to address the comment. It should be noted that the final rule now requires only an oxygen monitor.

Comment Excerpt Number: 32

Comment: The preamble of the proposed rule states that the daily records of fuel use are necessary to ensure that the affected source is complying with the emission limits from the correct subcategory. §63.7555(d)(1) indicates that monthly records are required for units that are subject to emission limits.

Fuel switching is not a daily event and therefore a monthly record is sufficient to ensure that the affected source is complying with the emission limits from the correct subcategory.

The fuel use recordkeeping requirement should remain on a monthly basis as proposed in 63.7555(d)(1). Recordkeeping should only be required when unit is in operation.

Response: EPA has not revised the fuel use records requirements in § 63.7555(d)(1). The final rule requires, monthly fuel use records be kept.

Comment: Proposed 63.7560(c) requires that You must keep each record on site for at least 2 years after the date of each occurrence, measurement, maintenance, corrective action, report, or record, according to 63.10(b)(1). You can keep the records off site for the remaining 3 years. Since most records are computerized and computer data storage is often not onsite, most rules now require either the 2 year on-site storage or ready access of computerized records from onsite. This paragraph should be modified to reflect the current state of technology.

Recommendation: Clarify 63.7560(c) to indicate that ready access of computerized records from onsite meets the two year onsite retention requirement.

Response: EPA has revised the record retention specifications in § 63.7560(c) to allow access from an on site computer network.

Comment: In the proposed rule, EPA proposes that all boilers and process heater units maintain daily records of fuel use that demonstrate that a facility has burned no materials that are considered solid waste. 75 Fed. Reg. at 32,015. This requirement requires facilities to prove a negative and should be reconsidered.
TFI requests that all natural gas-fired boilers and process heater units be exempt from this requirement, as these units are not configured to burn solid waste. If EPA does not exempt natural gas units from this requirement, TFI requests that EPA redefine this requirement so that facilities are required to maintain records of the specific days on which a unit burns materials that may be considered solid waste. If EPA does not redefine the requirement, TFI asks for some guidance on how a facility demonstrates that it has burned no solid waste materials on a given day.

Response: Daily records are not required. This was an error in the preamble that has been removed. Refer to DCN EPA-HQ-OAR-2002-0058-2797.1, excerpt 28 for additional information on de minimis quantities of non-hazardous secondary materials.

Comment Excerpt Number: 4

Comment: Fuel Usage Tracking should not be required where only one fuel may be burned. Proposed 40 CFR 63.7540(a)(10)(vi)(C) requires that at major sources for each boiler or process heater with a heat input capacity of 10 million BTU/hour or greater in the Gas 1 (NG/RG) or

Metal Process Furnace subcategories, a record be maintained of the type and amount of fuel used over the 12 months prior to each annual adjustment. Presumably, this is to be able to demonstrate that the unit meets the fuel usage restrictions for its subcategory. However, for boilers and process heaters that are physically or lawfully incapable of burning more than a single type of fuel (e.g., a natural gas fired boiler that is physically incapable of burning any other fuel, or a natural gas fired boiler that while physically capable or burning another fuel is legally prohibited from doing so even at times of natural gas curtailment, gas supply emergencies, etc.), there is no underlying reason to track the amount of fuel usage at this level. In many cases, fuel consumption at small boilers is not individually tracked or recorded and adding metering equipment and recordkeeping processes would impose additional expense without corresponding environmental benefit. We ask that this requirement be modified to exempt sources that are incapable of burning more than a single type of fuel. We suggest the following modification to proposed section 63.7540(a)(10)(vi)(C):

"The type and amount of fuel used over the 12 months prior to the annual adjustment, but only if the unit was physically and legally capable of using more than one type of fuel during that period."

Response: EPA has added the suggested language to § 63.7540(a)(10)(vi)(C).

Document Control Number: EPA-HQ-OAR-2002-0058-3122
Comment Excerpt Number: 28

Comment: Daily records of quantity, type, and origin of each fuel burned. This requirement is not achievable and conflicts with the monthly requirements in § 63.7550 and § 63.7555. It may not be possible to determine the origin of the fuel in the cases of a mixed coal pile from several sources and a mixed fuel oil tank from several sources. Daily fuel usage for facilities that do not have direct measurement systems such as coal weigh hoppers, belts or feed systems would have the added daily burden of calculating and recordkeeping activities for fuel usage when these facilities are only making fuel calculations on a monthly basis for permit compliance demonstration or other regulatory requirements. Some facilities proportionally average fuel parameters over much longer time periods (i.e., monthly) which provides more accurate values. EPA should require this information on a monthly basis, although there may be daily recording of steam produced, feed water temperature, etc.

Response: EPA has revised § 63.7555(e) in response to the comment and changed the heat input record requirements from daily to monthly. It should be noted that emission averaging compliance § 63.7522 is based on monthly heat inputs.

Comment: EPA's proposal includes requirements for the tracking of numerous data points, including fuel consumption; operating hours, startups, shutdowns including dates and times; equipment malfunctions including dates and times; numerous operating parameters including dates and times of deviations; GEMS, GOMS, and GPMS calibration and quality assurance/quality control data; GEMS, GOMS and GPMS maintenance information; GEMS, GOMS, and GPMS out of control periods including reasons, dates and times; performance test reports; fuel sampling reports; vendor reports; and a number of other pieces of information. Records must be kept of virtually all information referenced in the proposal, including all GPMS data required to be collected, for five years. Unfortunately, much of these data gathering requirements cannot be automated, but instead will have to be collected manually. Once the data are gathered, decisions will have to be made regarding what has to be reported and a report will have to be generated and certified. This will be a massive undertaking and the possibility of making an error during the process will be a virtual certainty.

To reduce manpower requirements most sources will likely attempt to automate as much of the reporting and record keeping as possible. The equipment costs alone for implementing an automated (to the extent possible) data collection and report generation system for a unit with multiple controls is likely to be very high and there may be little opportunity for standardization of the software. In short, NREGA does not believe that EPA, in proposing its enforceable operating limit approach, has adequately estimated or considered the data management costs of its proposal and requests that the agency do so.

Response: EPA has determined that the record keeping requirements are consistent with both the General Provisions in 40 CFR 63 Subpart A and other Clean Air Act programs using similar monitoring technologies and reflect the minimum requirements needed to demonstrate initial and continuous compliance.

Comment: Proposed Rule Language §63.7540(a)(2):
"As specified in §63.7550(c) you must keep records of the type and amount of all fuels burned in each boiler or process heater during the reporting period....."
Comments:
It is unclear whether the fuel use must be monitored by each heater and boiler or for the aggregate of all existing heater and boilers within a subcategory. As defined above, records must be maintained for each fuel burned in each boiler and heater subject to the rule. However, §63.7550(c)(4) defines the reporting requirements as the total fuel used by each affected source subject. The definition of affected source found in §63.7490(a)(1) as the collection of all existing boilers within a subcategory at a major source. The fuel monitoring requirement language is confusing and contradictory. Thelanguage should be revised to clarify whether the fuel must be monitored and reported on a per boiler and/or heater basis or for the aggregate of all units within a subcategory.
Fuel use records for Gas 1 heaters and boilers, as required under §63.7540(a)(10)(vi)(C), should be only required as an aggregate of those sources, since mo emission limits apply to them. In a refinery, these units typically have aggregate meters for refinery fuel gas.

Response: The EPA has determined that the reporting requirements are clear and no rule change is needed. Fuel must be monitored and reported on a per boiler and/or heater basis as each unit shall demonstrate compliance with the applicable emission limits unless a facility is using the emission averaging provision among similar existing units. It should be noted that the report described in § 63.7550(c) can include records from more than one unit.

Commenter Affiliation: American Petroleum Institute and National Petrochemical and Refiners Association
Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 13

Comment: The rule requires performance test results be submitted to the Agency in a specific electronic format. This will be additional effort for the performance test contractor and that extra cost and effort is not included in the burden estimate.

Production losses will be incurred under the provisions of this rule for process shutdowns associated with the burner tune-up requirements and special, uneconomic operations associated with the performance test requirements. This production related cost must be taken into account in evaluating this proposal.

Response: See the preamble for discussion of the electronic reporting mechanism.

Document Control Number: EPA-HQ-OAR-2002-0058-2854.1
Comment Excerpt Number: 5

Comment: Recommendation: Take the burden off smaller sources for providing data electronically. Consultant costs will be prohibitive, alongside the already high cost of testing. We suggest those having no units over 100 MMBTU/hr be allowed out of that requirement, but if that's too high for EPA then at a minimum those having only units 10 MMBTU/hr and lower should be exempt from that requirement.

At a recent training program, one of the SBEAPs reportedly learned that it can take a person—with experience using computers—a couple days to enter all the data into EPA's online system as required in 63.7550(h). The consultant fee was reportedly thousands of dollars, just for the data entry. If they cannot afford to have someone else enter the data, small business owners and their staff often lack basic computer use experience sufficient to maintain the most basic records and spreadsheets much less use a complex application on their own. In addition, many small businesses may not have the computing power to deal with a program in Microsoft Access and transfer files that it generates.

Until EPA can streamline this system and make it something anyone can easily use, the burden of online data entry should be left to the larger major sources that are better able to afford the cost.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Affiliation: RRI Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2759.1
Comment Excerpt Number: 5

Comment: In cases where an ICI Boiler is part of a Title V or state only operating permit, the local permitting agency has its own unique emission and compliance test reporting format. State and local agencies also enforce the specific conditions within these operating permits. In all locations where RRI Energy operates an industrial boiler, we are required to submit a hard copy of all compliance test results to the local permitting authority. To comply with the proposed rule, RRI Energy would be required to prepare a hard copy report for the state or local agency that issued the permit in addition to inputting the data into the Electronic Reporting Tool (ERT) or WebFIRE database when it becomes available. This is a duplication of effort, increasing the cost of reporting test information.

RRI Energy would like EPA to provide a listing of those states who will utilize the ERT or WebFIRE as its means of collecting emission test data to determine compliance.

Where a state or local agency does not adopt the ERT or WebFIRE reporting mechanism, or until such time local agencies do adopt the ERT or WebFIRE reporting, the regulated entity should not be required to duplicate reporting efforts. In these cases, compliance would be demonstrated by reporting in accordance with the permitting authority's requirements.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 305

Comment: The requirement for ERT reporting should be removed. Industry had many problems submitting Industrial Boiler MACT and CISWI ICR data using the ERT, and there are still many problems with the tool based on experience that utilities and testing firms are having while entering Utility Boiler MACT ICR data into the tool. Use of this tool will add cost and burden to the already costly emissions testing requirements in this rule. The tool is not a replacement for a stack test report, but rather an additional reporting burden, as permitting agencies will still require a hard copy stack test report with all supporting documentation.
The following are examples of issues encountered with the ERT:

* It is not intuitive and it is difficult to use.
* It is not set up to handle data from multiple stacks from the same source being tested at the same time.
* It only allows for one intermittent leak check during a test run. Many stacks have more than two ports so the ERT should be set up to handle those scenarios rather than having to add leak check volumes together to come up with a total.
* It is not set up to handle mixed blend calibration gases, which are extremely common.
* The import tool is inadequate, as it does not have enough rows for long runs and often imports data in the wrong order.
* The tool is not set up to handle blank corrections.
* The tool is "buggy" and slow to respond.
* The tool seems to only be designed to work under the most ideal of test scenarios, which is not always realistic. The EPA should ask for comments on the format and uploading tool from individuals that encounter actual real world scenarios for testing to incorporate into future editions.
* Revisions to the ERT should have a revision number such that the users can make sure the version they are using is the most recent version available.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 307

Comment: Compliance tests are submitted to the state or local permitting agency for review and approval. At times, the agency provides comments to the regulated facility that adjust the test results. In these cases, the information entered into the ERT at the time of the stack test would not match the final, state-approved emission test results. At a minimum, there needs to be a mechanism for the ERT data to be updated in these situations or a flag to indicate whether the report has been reviewed and approved by the permitting agency.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 308

Comment: EPA could require the permitting agency to enter the stack test results into the ERT once approved, rather than requiring facilities to enter the data.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 309

Comment: If use of the ERT is required, EPA needs to develop a comprehensive ERT Guidance Manual that provide complete instructions with examples for:
* all entries including:
* the various facility identification codes, and where to find them
* BDL instructions
* calibration instructions
* required attachments
* the “external” spreadsheets” that are used to import certain data into the ERT
* the “external spreadsheets” that are used for reporting test methods not currently supported by the ERT

EPA should also develop an “outreach” or “training” program that provides instructions for specific source categories and related parameters. Such efforts need to be readily-available – via presentations at relevant conferences/seminars, as well as web-based sessions (”webinars”).

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Robert D. Morrison
Commenter Affiliation: Abbott Laboratories
Document Control Number: EPA-HQ-OAR-2002-0058-2764.1
Comment Excerpt Number: 17

Comment: The proposed Boiler MACT rule includes a proposed requirement that all emission test results are to be submitted electronically, however, the Electronic Reporting Tool (ERT) that has been proposed as the reporting platform is inefficient and unworkable, and should be replaced with a more flexible and user-friendly electronic reporting tool (40 CFR 63.7550(h) and 75 FR 32015). Abbott supports USEPA’s intention to streamline reporting requirements through the use of electronic data transfer. However, we have significant concerns regarding ERT as it currently exists. ERT was required for data transfer from the testing program for USEPA’s 2009 Boiler MACT Section 114 request, which required extensive boiler testing. In that program, ERT proved to be an awkward, inefficient tool, and ultimately required two different reporting procedures and a delay in data submission due to the limitations of ERT. Abbott strongly recommends that a more flexible and user-friendly electronic reporting resource should be developed. An explicit regulatory reference for use of ERT without a commitment to improve it will have an immediate impact on facilities with new units, perhaps sooner than ERT can be revised, and existing units will also be impacted at some point.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Randall D. Quintrell
Commenter Affiliation: Georgia Paper and Forest Products Association, GPFPA
Document Control Number: EPA-HQ-OAR-2002-0058-2905
Comment Excerpt Number: 23

Comment: The proposed Rule’s requirement to use the Electronic Reporting Tool (ERT) for reporting test results is premature and ill-conceived. The ERT is, at least at present, a very poorly designed system which is very difficult to use. EPA does not even have a final version available for the regulated community to vet. Moreover, with the proposed testing requirements for inherently low emission units, it is known that many data points will be at or below the method detection limits and practical quantitation limits. Such data should not be reported electronically unless and until EPA has both developed and published (i) acceptable method detection levels and practical quantitation limits for dioxin/furan, mercury and HC1 testing, and (ii) protocols for handling non-detect data and data below the PQL. The ERT may eventually have a consistent format but that does not mean it has appropriate QA/QC functions. It also requires dedicated staff at EPA to provide quality assurance review of the data being submitted for the several thousand boilers subject to the Rule to ensure that the data are indeed valid and accurate before allowed into the database. Such method development, pre-reporting QA/QC criteria and post-reporting QA/QC validation are critically important to ensure that test results will be handled consistently and to prevent data which have not been subjected to adequate QA/QC from being made available for public distribution. Given that the Rule affects thousands of units with operators most of whom have never used a tool like the ERT the opportunity for error is significant, especially when combined with the poor design of the current ERT system. The potential damage caused by dissemination of inaccurate data is substantial. Moreover, it is counterproductive to EPA's stated purpose of generating meaningful accurate data for use as emission factors. To repeat the well known adage, "bad data is worse than no data" because it misinforms and leads to erroneous conclusions and bad decisions. The chance that this can and will happen with EPA electronic databases is illustrated by EPA's recent release of 2009 TRI data. Those data also are submitted electronically with a program does not allow the data to be viewed by the submitter for typographical errors or other mistakes after submission. The July 2010 data release was made without even providing the submitter an opportunity to review the data for such errors before it was made available to the public. Such reporting can always be added to Title V permits at a later date if and when EPA develops and maintains a properly designed system with necessary QA/QC criteria. In short, the requirement for electronic reporting using the ERT must be removed from the final Rule.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 157

Comment: Emission Reporting Tool (ERT) Problems
EPA is requiring submission of data via the Electronic Reporting Tool (ERT). 75 FR 32015. Notwithstanding EPA's assertions to the contrary, data submitted through the ERT is error-prone and imposes additional burdens on reporting sources because the ERT bypasses all data quality control. For the information collection process for the Boiler MACT suite of rules, EPA required sources to use the ERT. Sources had requested in the ICR proposal stage that EPA not utilize the ERT, which was going through Beta testing, and informed EPA that the ERT had serious flaws including difficulty of use, content problems and inaccessibility. EPA decided to use it for data collection for these rules. The concerns proved correct, however, as sources were compelled to use the ERT, which is a difficult and time-consuming tool for submission of test data. The ERT data compiled was riddled with mistaken entries, incorrect and missing data, and the ERT had generally faulty output. Then the problem was compounded when EPA relied on the inaccurate data, leading to multiple calculation and other inaccuracies.

Using the ERT doubles the burden on sources that take the time to enter accurate source data, only to see it distorted. They then must spend hours finding the data error and conferring with EPA personnel to fix the problem. Only then are they able to consider EPA's rule proposal and its impact on their sources. In part due to the ERT and resulting data problems, regulated sources sought an extension of the comment period. See Comment Extension Request, especially Description of the Development of the Boiler MACT Database (see submittal for comment extension request).

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 158

Comment: In the past, sources did compliance tests for the state, and the state approved the data. The state effectively conducted quality control on the data. The ERT bypasses the state, creating data quality issues. Using the ERT means that data is transmitted without any QC, and that results in multiple data errors. The ERT does not permit the easy identification or correction of errors. Reporting needs to be accomplished by whatever format permits the source to trace the same data throughout the process to ensure its integrity. This had been accomplished in the past by using the hard copy submitted to the State and a human looking at data to QC it. If there was a problem, this could be identified and resolved in the early stage, before the faulty data was applied to formulas.

CIBO urges EPA to adopt a reporting methodology that ensures the data is quality controlled, and errors can be traced easily to their origins. The ERT needs to be improved before it is required for data submission for compliance demonstration. Inaccuracies may be more tolerable during the rule-writing process, but once the rules are in place, the stakes are much higher, as faulty ERT output can create compliance issues for sources. EPA may prefer the administrative ease of the ERT, but that should not outweigh the need for regulated sources to have assurances of accurate data and compliance status.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 183

Comment: Proposed 63.7550(h) requires electronic reporting of all performance test results for performance tests required under this rule. We see no value in this requirement for CO from gas or oil-fired boilers and process heaters and recommend its deletion. There is no justification for imposing this requirement. The preamble attempts to justify the extra cost and burden of this requirement (which is significant for the multitude of sources subject to this proposal) on the basis that it will help improve emission factors and reduce the burdens associated with collecting data on emissions through 114 requests. We see no way collecting any amount of additional data would significantly improve the emission factors for gas or oil-fired boilers for CO, versus simply calculating the CO emissions using the extremely low emission limitation in this proposal. Furthermore, collecting thousands of CO performance test results doesn't help develop emission factors, because performance tests are all run at >80% of design firing and thus do not represent normal operation or normal operating variability for the vast majority of boilers or process heaters. Since the CO limits apply at all times, they are a much better approximation basis for emission estimating than any emission factor developed from performance test data on sources subject to such low emission limits.

Recommendation: Delete the electronic reporting requirement at least for CO from oil and gas fired units subject to CO emission limitations. Consider eliminating the electronic reporting requirement for other pollutants, since the arguments above also apply to them.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 184

Comment: The rule requires performance test results be submitted to the Agency in a specific electronic format. This will be additional effort for the performance test contractor because this requirement does not replace the need for a written report for site records and for submission to permitting authorities. In fact, it is unclear it replaces the General provisions requirement to submit a full report to EPA.

Recommendation: If electronic reporting requirements are maintained, clarify that the electronic submission of performance test results to EPA satisfies all EPA performance test reporting requirements.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Matthew Todd and David Friedman

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 230

Comment: We also request any performance tests submitted to the Agency through the electronic reporting system be exempted from the requirement to include those reports in the NCS, though the electronic submission should be referenced. There is no reason to require both. If a delegated authority wants a hard copy, their regulations will require it, but there should be no need for making both types of submissions to EPA.

Recommendation: Remove the requirement to submit performance test reports in the NCS, if the final rule requires them to be submitted electronically.

Response: See the preamble for discussion of the electronic reporting mechanism.

Comment: The proposed rule would require facilities to report test data using EPA's Electronic Reporting Tool. Stack test and analytical laboratories typically provide results via hardcopy test reports. The cost of contracting a test firm to enter data into the electronic database was not included in the annual stack testing costs.

Response: See the preamble for discussion of the electronic reporting mechanism.

Comment Excerpt Number: 1

Comment: Support the deployment of the Electronic Reporting Tool. The MPCA supports use of the Electronic Reporting Tool (ERT) for collecting performance test data, and encourages the U.S. Environmental Protection Agency (EPA) to properly assign resources to complete its development, as well as provide sufficient technical support for states to access submitted data in a timely fashion.

In addition to substantiating this proposed rule making, the MPCA believes when this database is available and populated, it will support a number of important aspects of the federal and state air quality programs such as improving emission inventories and air modeling inputs, as well as streamlining our assessment of emission tests and compliance determination.

It will be critical that this method of data collection and submittal be fully functional so that facility owners subject to this standard are not required to duplicate submissions to EPA and states.

Response: See the preamble for discussion of the electronic reporting mechanism.

Comment: Our experience with the ERT on both the Boiler MACT/CISWI and Electric Utility ICRs has not been positive. It is based on an “armchair” approach to source testing and does not allow for adjustments in data collection that are necessary to accommodate sampling at each source. We both appreciate and understand the need to expedite data transfer and eliminate the need for re-entry of data; however, the current version of the ERT is difficult and time-consuming to use. WESTON relies extensively on electronic data capture and reporting for emission testing projects. Even so, we believe that - depending on the scope of work - use of EPA’s ERT and SRTs add 8 to 24 hours per source for a mid-professional level person with previous ERT experience.

Comment: The ERT was used extensively in the Boiler MACT and EGU MACT ICRs. Reporting emissions data using the ERT is time consuming and represents an unnecessary burden to the regulated community. Compliance data reporting software should minimize the burden on the regulated community by requiring only those data required to demonstrate compliance. This would include the raw emissions data and a limited amount of boiler and control device operating information from the emissions test period. It should also follow a transparent development process that includes feedback from the regulated community. The proposed use of the ERT does not meet either of these requirements. We recommend that EPA eliminate this requirement from the proposed rule.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 67

Comment: EPA proposes that, after December 31, 2011, sources must submit all compliance test results to EPA using the Electronic Reporting Tool (ERT) software or "other compatible electronic spreadsheet". The ERT was used extensively in the Boiler MACT and EGU MACT ICRs. Our experience with this software suggests that reporting emissions data using the ERT is time consuming and represents an unnecessary burden to the regulated community. We recommend that EPA eliminate this requirement from the proposed rule unless or until EPA can establish the necessary statutory authority to develop such software.

Assuming EPA can establish such authority, compliance data reporting software should minimize the burden on the regulated community by requiring only those data required to demonstrate compliance. This would include the raw emissions data and a limited amount of boiler and control device operating information from the emissions test period. It should also follow a transparent development process that includes feedback from the regulated community. [Footnote: EPA followed this process in their development of the Clean Air Markets Division (CAMD) Emissions Collection and Monitoring Plan System (ECMPS) software.] The proposed use of the ERT does not meet either of these requirements.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 77

Comment: Section 63.7540(a)(9)(iv) of EPA's proposed rule requires that, after December 31, 2011, all test data used to demonstrate compliance be entered electronically into EPA's WebFire database within 60 days of completing a performance demonstration.

EPA provides no insight or justification in the preamble or otherwise for requiring this form of data submittal. The cost of this requirement, as compared to conventional reporting, is not evaluated or disclosed in discussion of the cost and impact of the proposed rule. Although a number of affected facilities may be already trained and equipped to accomplish such electronic reporting, many of the affected facilities have not had to participate in such reporting procedures in the past. These facilities will require additional staff time, equipment and training to accomplish this requirement. The proposed effective date of this requirement means that even the initial reporting must be conducted electronically. This further burdens the affected facilities in unnecessarily having to develop new reporting techniques and procedures concurrent with the other tasks required to implement a new rule. EPA has failed to describe any benefit of this requirement as compared to these additional burdens.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 79

Comment: It is also likely that implementation of the initial testing, much less any later testing, will be accomplished under state authority. Unless state agencies are willing to use this same electronic reporting tool, facilities will have a dual requirement for reporting. EPA has also failed to describe any effort to convince state agencies to use this tool as their preferred reporting mechanism.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Shelley Schneider
Commenter Affiliation: Nebraska Department of Environmental Quality
Document Control Number: EPA-HQ-OAR-2002-0058-2820.1
Comment Excerpt Number: 3

Comment: The proposed standards require sources to submit their performance test data electronically to EPA through the WebFIRE software. NDEQ appreciates that having the data submitted electronically will produce a larger data set EPA can utilize to develop more accurate emission factors. Conversely, if sources are not required to submit a paper copy of the test results to the state/local permitting authority, the data can not be reviewed and quality assured. The WebFIRE software does not have quality assurance flags to alert EPA that a test was conducted improperly or whether the data is accurate. Utilizing inaccurate or false data could lead to nonrepresentative emission factors and potential noncompliance with the emission limits.

NDEQ requests EPA include a provision to require facilities to submit their testing results to their state/local permitting authority in addition to submitting the data electronically. The Nebraska Air Quality Regulations require facilities to provide emissions test results to NDEQ within 45 days of completion of the test. Not including this provision in the standard may unnecessarily result in noncompliance with the state regulations and may result in inaccurate test data.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Wayne J. Galler and Deborah A. Phillips

Document Control Number: EPA-HQ-OAR-2002-0058-2882.1
Comment Excerpt Number: 14

Comment: The proposed requirement to use EPA's Electronic Reporting Tool (ERT) for reporting stack testing results is premature and ill-conceived. The ERT is, at least at present, a very poorly designed system making it extremely difficult to use. For example, the program is not designed to allow the user to review the work to correct errors or omissions before the information is submitted. Numerous other problems also exist with the software that are described in more detail in GPFPA's comments. These problems need to be addressed and corrected by EPA before this tool can be easily used by industry,otherwise, the tool will become an administrative burden, adding cost and time to industry's compliance requirements.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Martha E. Rudolph
Commenter Affiliation: State of Colorado
Document Control Number: EPA-HQ-OAR-2002-0058-2940.1
Comment Excerpt Number: 14

Comment: The State intends to continue to request sources to submit stack test reports to the State, in addition to EPA's collecting stack testing data via the Electronic Reporting Tool (ERT). The State appreciates EPA's need to readily access stack test data and applauds efforts to improve emission factors. However, the State believes that the stack test data reported must be considered along with additional, specific information for each source's operations. This evaluation cannot be easily conducted with the limited data reported in the ERT. The State believes that the stack test data submitted in the ERT, taken at face value, may be misleading unless the context in which the testing was completed is understood. Until the number and degree of source configuration and operation variables can be adequately accounted for and reported in one reporting tool, allowing the associated test data to be wholly considered, the State will continue to request stack test reports be submitted to the State.

Response: See the preamble for discussion of the electronic reporting mechanism.

Document Control Number: EPA-HQ-OAR-2002-0058-2835.1
Comment Excerpt Number: 30

Comment: NRECA objects to EPA's proposed requirement to report using the electronic reporting tool ("ERT") and disagrees with EPA's assertions regarding the impact of that requirement on reporting and on emission factor development. As UARG notes in its comments, while experience with the ERT has been limited, industry nonetheless has identified a number of shortcomings in the programs. Furthermore, use of ERT is burdensome (easily adding 10-20 percent to the cost of compliance testing), requiring manual inputting of significant amounts of information much of which is not relevant to performance test results. It also is subject to significant performance issues, including software crashes and shutdowns, inoperable features (like report generation), and inadequate identification of errors preventing data analysis. In short, even if EPA can justify a requirement to report performance test data electronically, EPA cannot justify requiring sources to use this program.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Affiliation: Georgia-Pacific LLC

Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 42

Comment: The requirement to report the results of emissions testing and collateral data using the Emission Reporting Tool (ERT) needs to be re-evaluated. Georgia-Pacific's experience is that the version of the ERT that existed during the Phase II data collection testing (2009) was difficult and cumbersome to use and not sufficiently robust to handle all the data given the lack of guidance provided by EPA concerning parametric reporting for that effort. To that extent, only one of nine facilities' environmental personnel completed the ERT; all others had to pay the testing contractor additional money to do the reporting.
Looking forward, the difficulty of ERT use for the average environmental coordinator at any given location suggests that more of this work will be contracted out in the future. This would result in both additional expense to the location and in unnecessary administrative compliance risk simply because it would be difficult for that environmental coordinator to adequately review stack tester data input for correctness and completeness absent a fundamental working knowledge of ERT and how its database works. In short, it would be very easy for a stack tester to mischaracterize some aspect of the facility in the ERT that may not be caught by the submitting facility personnel.

ERT is simply not reliable enough or robust enough to be used as compliance tool under the MACT standard.

Response: See the preamble for discussion of the electronic reporting mechanism.

Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 43

Comment: The ERT is in Microsoft® Access, a software platform that has some serious inherent weaknesses. We found this to be increasingly slower to update the more records we put in. In some cases, we had to combine records instead of reporting individual process records simply because the ERT was not robust enough to handle the level of detail we were prepared to put in the system. Access also appears to "automatically update" the ERT records file every time we opened it as opposed to asking us if we wanted to save changes. This file update makes it impossible to make an archival electronic copy of the ERT records file for reference unless the file was never to be opened again for any other purpose.

Response: See the preamble for discussion of the electronic reporting mechanism.

Comment: We also observed a very clear lack of instruction on how to set up records in the entry screens. The examples listed below are not intuitive; we simply arrived at these by trial and error.
o It was not at all clear that calibration sets needed to be set up as pre-requisites for run files, and that each calibration gas for each parameter needed to have a unique name even though the gases may have come from the same bottle.
o It was not at all clear how or if process data record numbers correspond to actual test run numbers. Further, it was not at all clear why process run numbers appeared to be limited to some small number less than 20.
o It was not intuitive how to add or delete records.

Response: See the preamble for discussion of the electronic reporting mechanism.

Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 45

Comment: The report viewers in the ERT did not give us the “full” results of our data entry. This could result in remnants of “unintended for submission” remarks or comments from draft entry hanging around in the database without the facility realizing they were there in there even after reviewing the full report in the report viewers. In essence, we could be certifying the submission of something we did not even know was there. This is unacceptable.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Affiliation: Georgia-Pacific LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 48

Comment: The ERT was not compatible with all pollutants. No guidance was provided as to when to report oxygen or carbon dioxide (at least one of these was used as a diluent for all other pollutant runs). The ERT asked for redundant data (e.g. run duration plus start and end times). The F-factor field was confusing and the ERT did not distinguish between a blank and a zero. So, for example, we used Fc. We had no need for Fw and didn't enter or address it. Instead of the ERT properly characterizing Fw as blank, the final report showed Fw = 0, which is clearly not what we intended.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Affiliation: Georgia-Pacific LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 50

Comment: The indexing of stack test run numbers was cumbersome. The program picked run numbers sequentially instead of allowing a facility to enter something much easier for identification. So, for example, we needed to know that runs number 23 to 25 were CO runs to find out anything about them after data entry, instead of allowing us to enter an identifier like "CO Run 1", "CO Run 2", or "CO Run 3." In a related matter, the numbering conventions did not allow associations. For example, oxygen tests run simultaneously with CO could have been numbered 1 and 23, respectively, but not the more-intuitive "O2 Run 1" and "CO Run 1."

Response: See the preamble for discussion of the electronic reporting mechanism.

Comment Excerpt Number: 51

Comment: We found the pick list run number sorting sequence bothersome. Given the numbers 1, 10, 11, and 2, the more intuitive sequence of 1, 2, 10, and 11 is not used by Access. Rather, the pick list puts these in this order: 1, 10, 11, and 2.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 62

Comment: UARG objects to EPA's proposed requirement to report using ERT and disagrees with EPA's assertions regarding the impact of that requirement on reporting and on emission factor development. On December 14, 2009, UARG provided comments in response to the Agency's Advance Notice of Proposed Rulemaking ("ANPR") at 74 Fed. Reg. 52,723 (Oct. 14, 2009) soliciting comment on a number of aspects of emission factor development, including the possibility of requiring submission of all compatible Part 60 and Part 63 to WebFIRE using ERT. EPA-HQ-OAR-2009-0174-0040 (incorporated by reference). In those comments, UARG noted that its members' experience with ERT was limited, but nonetheless noted a number of shortcomings in the program that were sufficient by themselves to cause UARG to object to any requirement to use ERT. UARG members have gained more experience with ERT in recent months that has simply confirmed and elevated those objections. Use of ERT is burdensome (easily adding 10-20 percent to the cost of compliance testing), requiring manual inputting of significant amounts of information much of which is not relevant to performance test results. It also is subject to significant performance issues, including software crashes and shutdowns, inoperable features (like report generation), and inadequate identification of errors preventing data analysis. In short, even if EPA can justify a requirement to report performance test data electronically, EPA cannot justify requiring sources to use this program.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 63

Comment: UARG also has a number of legal concerns with EPA's proposal. First, EPA has made no effort in its proposal to identify the software it proposes to require, other than by name. If EPA finalized this rule, EPA could substitute virtually any version of this program, or even another program by the same name and attempt to mandate its use. For EPA to promulgate an enforceable software requirement, EPA must identify the software with sufficient specificity that it can be incorporated by reference into the rule. If EPA simply wants to require electronic reporting, EPA should limit its requirement to a specific format (e.g., xml) and allow sources to procure or develop their own software to comply with that format and the associated reporting elements.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 64

Comment: Contrary to EPA's assertion, ERT as currently designed requires the reporting of vast amounts of information that are not otherwise required to be reported under the applicable EPA test methods, or EPA's proposed rule. A brief comparison of the reporting requirements in Method 5 (40 C.F.R. Part 60, Appendix A, Method 5, § 11.2.2 and 11.2.4 -- "[r]eport the results to the nearest 0.1 mg") with EPA's description of ERT in its Electronic Reporting Users Guide Version 3.1, June 2009 (creating test plan, run data, test data, process data, etc.) illustrates this point. Similarly, EPA's proposed requirement in § 63.7550(h) to report "test data" is not sufficiently detailed to support reporting of all of the information that must be entered into ERT in order to submit data. To comply with the Paperwork Reduction Act and its implementing regulations, EPA must specifically identify each piece of information it seeks to have reported, explain how those data have practical utility, and estimate the costs of collection and EPA review of those data. EPA has done none of that. If EPA intends to require reporting of more than the test results already required to be reported under the applicable EPA test methods, EPA must issue a supplemental proposal identifying and soliciting comment on the information it seeks to collect.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 65

Comment: Any electronic report used to satisfy federal reporting requirements also must meet the requirements of the Cross-Media Electronic Reporting Rule, codified at 40 C.F.R. Part 3, including the requirement that the document include a valid electronic signature, as defined in the rule. EPA has made no attempt to explain how ERT or WebFIRE meet this requirement. UARG also is concerned regarding the ability of ERT to satisfy other criteria EPA deems necessary for valid electronic reporting, including whether (i) each electronic signature was a valid electronic signature at the time of signing; (ii) the electronic document cannot be altered without detection at any time after being signed; and (iii) each signatory had the opportunity to review in a human readable format the content of the electronic document that he or she was certifying to, attesting to or agreeing to by signing. See., e.g., 40 C.F.R. § 3.2000(b)(5). In UARG's experience, ERT satisfies none of these criteria. Especially troublesome is the inability of the responsible official to prevent revision of the information in ERT at or after the point of submittal. EPA cannot require sources to submit data using a mechanism that does not satisfy its own requirements for such submissions. Promises by EPA that these issues will be addressed by the time reports must be submitted are not sufficient to satisfy EPA's obligations under the CAA to provide notice and opportunity for comment at the time of proposal.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 66

Comment: UARG does not agree with EPA's unsupported assertion that the information required to be submitted under ERT to WebFIRE will benefit EPA and sources by improving emission factors. EPA has yet to explain in any detail how the process of emission factor development from performance test data submitted to WebFIRE will work. In its comments on the ANPR, UARG expressed concerns about the process EPA described and objected to any attempts to mandate submission of reports before EPA had more completely explained its plans, completed any necessary rulemakings, and made operational its website. UARG reiterates those points here. EPA should not be promulgating requirements intended to support a larger program piecemeal before that program has been fully developed. See, e.g., UARG Petition for Reconsideration of Portions of Final Standards for Coal Preparation and Processing Plants, EPA-

HQ-OAR-2008-0260 (Dec 7,2009) at 8-9 (incorporated by reference).[33 EPA granted UARG's request for reconsideration of the ERT/WebFIRE reporting requirement in Part 60, Subpart Y on March 3, 2010.] EPA should reserve the question of mandatory reporting to WebFIRE until it has resolved the questions raised in the ANPR.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 227

Comment: EPA SHOULD REMOVE THE ERT RECORDKEEPING REQUIREMENTS. The requirement for ERT reporting should be removed. Industry had many problems submitting Industrial Boiler MACT and CISWI ICR data using the ERT, and there are still many problems with the tool based on experience that utilities and testing firms are having while entering Utility Boiler MACT ICR data into the tool. Use of this tool will add cost and burden to the already costly emissions testing requirements in this rule. The tool is not a replacement for a stack test report, but rather an additional reporting burden, as permitting agencies will still require a hard copy stack test report with all supporting documentation.

The following are examples of issues encountered with the ERT:

It is not intuitive and it is difficult to use.

It is not set up to handle data from multiple stacks from the same source being tested at the same time.

It only allows for one intermittent leak check during a test run. Many stacks have more than two ports so the ERT should be set up to handle those scenarios rather than having to add leak check volumes together to come up with a total.

It is not set up to handle mixed blend calibration gases, which are extremely common.

The import tool is inadequate, as it does not have enough rows for long runs and often imports data in the wrong order.

The tool is not set up to handle blank corrections

The tool is "buggy" and slow to respond.

The tool seems to only be designed to work under the most ideal of test scenarios, which is not always realistic. The EPA should ask for comments on the format and uploading tool from individuals that encounter actual real world scenarios for testing to incorporate into future editions.

Revisions to the ERT should have a revision number such that the users can make sure the version they are using is the most recent version available.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 229

Comment: Compliance tests are submitted to the state or local permitting agency for review and approval. At times, the agency provides comments to the regulated facility that adjusts the test results. In these cases, the information entered into the ERT at the time of the stack test would not match the final, state-approved emission test results. At a minimum, there needs to be a mechanism for the ERT data to be updated in these situations or a flag to indicate whether the report has been reviewed and approved by the permitting agency. Alternatively, EPA could require the permitting agency to enter the stack test results into the ERT once approved, rather than requiring facilities to enter the data.

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 230

Comment: If use of the ERT is required, EPA needs to develop a comprehensive ERT Guidance Manual that provide complete instructions with examples for:

all entries including:

the various facility identification codes, and where to find them

instructions on handling of non-detects

calibration instructions

required attachments

the "external" spreadsheets" that are used to import certain data into the ERT

the "external spreadsheets" that are used for reporting test methods not currently supported by the ERT

Response: See the preamble for discussion of the electronic reporting mechanism.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 231

Comment: EPA should also develop an "outreach" or "training" program that provides instructions for specific source categories and related parameters. Such efforts need to be readily-available – via presentations at relevant conferences/seminars, as well as web-based sessions ("webinars").

Response: See the preamble for discussion of the electronic reporting mechanism.

Recordkeeping and Reporting: Streamlining NSPS

Commenter Name: Robert D. Morrison
Commenter Affiliation: Abbott Laboratories
Document Control Number: EPA-HQ-OAR-2002-0058-2764.1
Comment Excerpt Number: 16

Comment: Boiler size categories in the proposed rule should be consistent with categories promulgated in the Boiler NSPS. In most, if not all, cases where monitoring is specified for the Boiler MACT, subcategories are proposed as less than 100 MMBtu/hour, 100 MMBtu/hour or more, less than 250 MMBtu/hour, and 250 MMBtu/hour or more. In that way, the few units rated exactly at a monitoring applicability threshold are assigned to the larger and more stringent of the two categories.

On the other hand, applicability of the New Source Performance Standards (NSPS) for steam generating units (40 CFR 60, Subparts Db and Dc) are based on rated capacity less than or equal to 100 MMBtu/hour, greater than 100 and up to 250 MMBtu/hour, and greater than 250 MMBtu/hour. As new units are constructed, it will promote consistency for monitoring provisions of the Boiler MACT and Boiler NSPS if both regulations use the same boiler size categories. Since the NSPS applicability criteria are established and the Boiler MACT are not, it would seem more efficient to modify all Boiler MACT classifications on boiler firing rate to conform with the NSPS.

Response: EPA agrees that the size categories should match the NSPS and has made the change. In the final rule no distinction is made at the 100 mmBtu/hr capacity rating, but the 250 mmBtu/hr is still relevant for the PM CEMS requirement.

Comment: FSI strongly supports the ability to take federally enforceable limits on materials/fuels combusted in order to no longer be subject to a particular set of rules. Boilers can be designed for combusting multiple fuels, including biomass and materials that may become solid waste under the Section 129 rules. In practice, boilers can burn an array of fuels/materials, depending on fuel value, cost, and other factors. Fuel switching can be an important practice at any larger industrial facility in order to remain competitive and minimize fuel costs. Managing fuels is also important in reducing fossil fuel usage, which promotes the nations? energy independence. Therefore, the ability to switch fuels/materials combusted should be allowed, provided the applicable rules are met. A “once in, always in” requirement is nonsensical, and would not provide any major benefits.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2837.1, excerpt 2 for a response to issues related to a combustors fuel mix and rule applicability.

Comment: Proposed Section 7525 contains provisions that require the collection of valid emissions data from CEMS and COMS for all operating hours per respective averaging period. the requirement to have valid emissions data for all operating hours is not realistic. Other established monitoring regulations, such as Sections 48 and 49 of 40 CFR Part 60 Da, do not contain such requirements and establish minimum valid data collection requirements. EPA should amend the following Section 63.7525 provisions to provide consistency with Part 60.48 and 60.49 monitoring and reporting requirements:
Proposed Section 63.7525(b) requires PM CEMS, on boilers > 250 mmBtu/hr, to record every hour for a 24 hour block and the collection of valid emissions data for all operating hours per 30-day rolling average. Section 60.48Da(p) of Subpart Da provides the operator the option to use PM CEMS to determine compliance with the PM emission limit and specifies that at a minimum, valid CEMS hourly averages shall be obtained for 75 percent of all operating hours on a 30-day rolling average basis (which will increase to 90 percent beginning on January 1, 2012). EPA

should amend the provisions of proposed Section 63.7525(b) to be consistent with Part 60.48Da(p).
Proposed Section 63.7525(a) requires CO CEMS, on boilers > 100 mmBtu/hr, to record every hour for a 30-day rolling average. Subsection (a)(6) states that any period when data is not available would be a "deviation from the monitoring requirements." EPA should amend these provisions to make the requirements consistent with existing monitoring requirements under Part 60.49Da(f)(2) where 90% of the operating hours in the 30-day averaging period must be valid. Provisions should also be added that would allow alternative compliance options at the discretion of the administrator for unusual circumstances that make this unusually difficult, such as low operating time for the source.
Proposed Section 63.7525(c) requires COMS record every 10 seconds for a 6-minute rolling average. Subsection (c)(6) states that any period when data is not available would be a "deviation from the monitoring requirements." COMS requirements should be consistent with 60.48Da(o)(2).

Response: CO CEMS requirements have been removed from the final rule. Regarding comments on PM CEMS, we have modified the language from the proposed 24-hour block to a 30-day rolling average. We disagree with the commenter about applying the data availability used in Da to the PM CEMS data collection. The Agency has developed a better understanding of the need for continuous data collection since Da was published and the equipment and software have dramatically improved as shown by the acid rain program CEMS data availability success. The monitoring system must operate at all time the process is operating.

Comment: The very existence of two proposals, Maximum Achievable Control Technology (MACT) for Boilers at Major Sources and the New Source Performance Standards (NSPS) for Commercial and Industrial Solid Waste Incinerators (CISWI), with different emission standards, possibly subject to revision based on comments and/or litigation, is an argument in favor of allowing the owner or operator of an affected source to change their status. In addition, there is also a proposed change under the Resource Conservation and Recovery Act (RCRA), "Identification of Non-Hazardous Secondary Materials that are Solid Waste," which is a complicating factor in the decision-making process for those affected by this rulemaking.

There are many uncertainties in the proposals, including what materials may be categorized as non-hazardous solid wastes for the purposes of combustion. The RCRA determination is not to be based on the health and environmental impacts of controlled emissions from the combustion unit, but rather on a definition of what is a waste (and by inference, what is a fuel). The emission limits in the boiler MACT and the NSPS for CISWI vary by subcategory within each proposed rule. For some emissions, it may be to the facility’s benefit to be classified as an incinerator, and for others as a boiler. Faced with these complexities, the owners and operators of boilers and process heaters must be given the opportunity to evaluate the environmental and economic effects of the variety of possible choices and either opt-in or opt-out of regulation under one or the other of the proposed rules.

There are many existing facilities subject to the proposed rule in our state. Some of these have been legally permitted to burn a variety of alternative fuels for many years. The DNRE Air Quality Division’s enforcement records show that these facilities have not caused emissions that harmed the public health and natural resources. The proposed rule, "NESHAP for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters," will change the legal status of some of these facilities without any modification on their part. Based on the complexities associated with the existence of the several applicable proposed rules, we encourage EPA to allow the affected sources the flexibility to determine and to revise their permits and operational status.

Response: Sources can change their fuel mix to establish which rule they are subject to. The requirements are presented in the rules.

Comment: Biomass Fuel Testing. The requirements in the rule for biomass fuel testing appear to be extremely onerous. Testing each time a new fuel supply is used can cost tens of thousands of dollars. In any given year, a mill might have 40-50 different fuel suppliers – wood is wood. Also, as written, the fuel testing will potentially result in unwarranted determinations of non-compliance due solely to normal variability of Hg, dioxin and HCl in wood fuels and/or laboratory analytical quantification limits on any given day.

Response: See response to comment EPA-HQ-OAR-2002-0058-2805.1, excerpt 8 for the definition of fuel type as it relates to biomass. According to the definition of fuel type, a change in fuel supplier in and of itself does not necessitate retesting.

Commenter Affiliation: Alcoa Inc

Document Control Number: EPA-HQ-OAR-2002-0058-2967.1
Comment Excerpt Number: 12

Comment: Proposed §63.7530 would require the owner or operator to establish maximum fuel pollutant input levels for chlorine, mercury and/or total selected metals based on fuel composition during compliance testing. This requirement is not workable because the facility may not be able to obtain or process the "worst case" fuel during compliance testing to maximize the fuel pollutant content. Pollutant content will vary in available fuels, and a requirement to conduct additional testing to reset maximum fuel pollutant input levels for available fuels will be very time consuming and expensive and is unnecessary for units capable of operating below the applicable emission standard. Alcoa recommends that EPA allow additional flexibility for establishing the maximum fuel pollutant input levels by considering both pollutant input levels during the compliance test and the measured emission rate relative to the standard. For example, the tested input level and emissions could be prorated to a level equivalent to 90% of the emission standard to allow operating flexibility while still ensuring continuous compliance with the standard.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for flexibility in exceeding the maximum fuel input.

Comment: Fuel Analysis Testing - §63.7521(c)(1)(ii)
As stated, composite fuel samples will be collected during the compliance tests. This procedure will not accurately account for the variability of the various constituents in the coal. Specifically, the concentrations of chlorine and mercury tend to be quite variable. EPA's guidance document for the 114 Phase II ICR acknowledged and addressed this concern for variability by requiring 10 samples over a 30 day period. The University suggests that this same procedure should be used when collecting the annual compliance samples.

Response: The commenter notes that the ICR testing program required 10 samples collected over 30 days. The rule requires at least three stopped belt samples (or ASTM sampling) collected over the period of a performance test (i.e., a few hours). If a source believes that the number of samples required in 60.7521 is not representative of the mercury or chlorine levels in their given fuel, they may propose in their site-specific fuel analysis plan that more samples be taken. In an effort to minimize burden while accounting for fuel variability, EPA has established a minimum of three stopped belt samples, and five truck or fuel pile samples.

Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 27

Comment: EPA has not provided a clear definition as to what constitutes new fuel. Unlike liquid fuels and coal, most biomass fuels are inherently inhomogeneous. For example, does a wood chip facility need to test for Hg and HCl for every new load or new supplier of fuel? As proposed, the language is unclear as to when a facility must conduct a test to show compliance with emission limits when fuel switching occurs, or the frequency of this testing. NESCAUM recommends that EPA clarify this rule to require testing upon use of a new fuel. Additionally, NESCAUM recommends that EPA not require facilities burning biomass to conduct fuel testing on each new load of biomass nor when a facility switches biomass fuel suppliers.

Response: See response to comment EPA-HQ-OAR-2002-0058-2805.1, excerpt 8 for clarification of fuel type with respect to biomass fuels.

Commenter Name: Britt S. Fleming

Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 43

Comment: Proposed § 63.7520(c), which requires testing using the highest content of chlorine and mercury while testing at the maximum normal operating load. It is not possible for sources using landfill gas to change the chlorine and mercury content for purposes of a performance stack test. Furthermore, since these types of boilers do not typically operate at maximum load, maximum normal operating load would need to be replaced with maximum available load during the performance test in order to properly account for these units.

Response: The facility is responsible for demonstrating that they are able to continuously comply with the emissions limits when operating under expected operating conditions. If a stack test does not represent the range of combined process and control measure conditions under which the facility expects to operate, the delegated agency may determine that retesting is warranted.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 50

Comment: The proposed compliance demonstration and monitoring requirements for fuel-dependent HAP emission limits are unworkable and do not provide compliance certainty for complex sites using fuels with variable fuel dependent HAPs.

EPA has proposed that sources demonstrate initial and on-going compliance with the mercury and hydrogen chloride emission standards by establishing the maximum HAP content (mercury or chlorine) in each fuel type (“coal” is a fuel type) from a minimum of just three composite samples and calculating the 90th percentile confidence level (P90) from these three samples. In a case where the source must rely on removal efficiency of the boiler system and/or air pollution control system to comply with the emission standard, the P90must be determined from three samples taken during the 3-run performance test. Thereafter, the EPA proposal requires the source to maintain records of the amount of each fuel type burned and to calculate P90 each time a new fuel type is burned. If P90 for the new fuel type is higher than the previous determination, a new performance test must be conducted (unless the source is complying with fuel analysis alone).

Given our knowledge of the variability of a fuel such as bituminous coal, use of this simplistic compliance procedure raises concerns regarding our compliance obligations. Under Title V Operating Permits, sources are required to submit annual certifications of compliance. Also, the issue of Credible Evidence is of concern if we have knowledge that coal we are supplied does not always have chlorine or mercury levels below the respective P90 values.

The wording of the proposed rule would require redetermination of P90 only when the fuel type is changed. However, the preamble (page 32014) states that the recalculation must be done when “you plan to burn a new fuel, a fuel from new mixture, or a new supplier’s fuel that differs from what was burned in the initial performance tests.” This would be unworkable for a complex facility such as Eastman that has as many as 20 different suppliers of a highly variable fuel (coal) which vary from year to year. This requirement would likely interfere with our business need to purchase coal from the spot market, particularly during periods when the coal market is tight. Also, a three composite sample taken on the same day is not likely to represent the long-term variability of even a single supplier, much less the variability of a broad fuel “type” such as coal.

Response: EPA has provided several provisions including multiple composite samples, annual averaging (for determining compliance using fuel analyses) or three test runs for stack tests, coupled with requiring a 90th percentile confidence level, to address variability in a given fuel supply. Sources must develop and submit a site-specific fuel analysis plan which may specify the use of a greater number of composite samples as necessary to address fuel variability, and must conduct performance tests using fuel that has the highest expected levels of chlorine and mercury. The commentor is concerned, in part, that the requirement to perform fuel analyses when they plan to burn a new fuel, a fuel from new mixture, or a new supplier’s fuel that differs from what was burned in the initial performance tests will interfere with their practice of using many different fuel suppliers. The regulation does not, however, require that fuel analyses be performed with each new fuel supplier, if the fuel supplied does not differ from the type of fuel burned in the initial performance test.

Comment Excerpt Number: 51

Comment: In order to have a workable and enforceable compliance program that adequately assures continuous compliance with the emission standards, we suggest a different monitoring program be allowed as an option. Here, a source would develop a fuel sampling plan customized for its specific fuel types. For example, for Eastman's coal supply, we could sample (using standard ASTM sampling methods) and analyze each shipment of coal for heating value, chlorine and/or mercury content, and store that data in a spreadsheet along with the quantity of coal in the shipment (e.g. number of cars). The source can then calculate the weighted average lb/mmBtu feed rate of chlorine and/or mercury fed to a given boiler (or set of boilers that are served by a common coal feed system) on a rolling average basis. On a monthly basis, a compliance determination that the 12 moving average chlorine and/or mercury feed rate is less than the allowable feed rate would be made. For a unit not relying on the system control efficiency, that allowable feed rate would be equal to the emission standard, expressed as lb/mmBtu. For a unit that does rely on system control efficiency, the source should be allowed to establish an allowable feed rate based on a successful performance test by extrapolating from the actual feed rate and actual emission rate measured during the test.

This approach would follow closely with the compliance program used to comply with the Hazardous Waste Combustor MACT (40 CFR 63 Subpart EEE). In this rule, each source develops and implements a Feedstream Analysis Plan to adequately characterize the materials to be incinerated and then track the feed rates of parameters such as chlorine, metals, and ash to ensure they stay below the allowable feed rates established from a Comprehensive Performance Test. We note particularly that Subpart EEE specifies up to an annual rolling average for mercury for liquid fuel boilers (see 40 CFR 63.1209(l)(1)(ii)).

In order to facilitate incorporation of this compliance option, we have included some suggested regulatory language:

§63.7530 (b) If you demonstrate compliance through performance stack testing, you must establish each site-specific operating limit in Table 2 to this subpart that applies to you according to the requirements in §63.7520, Table 7 to this subpart, and paragraph (c)(4) (b)(3) of this section, as applicable. You must also conduct fuel analyses according to §63.7521 and establish maximum fuel pollutant input levels according to paragraphs (c)(b)(1) through (3) (2)or (3) of this section, as applicable.
****
(3) Extrapolation of feedrate levels. In lieu of establishing mercury and/or chlorine feedrate limits as specified in paragraphs (b)(1) through (2) of this section, you may request as part of the performance test plan under §§63.7(b) and (c) and §§63.7520(a) to use the mercury and/or chlorine feedrates and associated emission rates (HCl in the case of chlorine) during the comprehensive performance test to extrapolate to higher allowable feedrate limits and emission rates. The mercury and/or chlorine feedrates shall be expressed as pounds per million Btu heat input. The extrapolation methodology will be reviewed and approved, as warranted, by the Administrator. The review will consider in particular whether:

(A) Performance test mercury and/or chlorine feedrates are appropriate (i.e., whether feedrates are at least at normal levels; depending on the heterogeneity of the fuel, whether some level of spiking would be appropriate; and whether the physical form and species of spiked material is appropriate); and

(B) Whether the extrapolated feedrates you request are warranted considering historical mercury and/or chlorine feedrate data.

§63.7530 (c) If you elect to demonstrate compliance with an applicable emission limit through fuel analysis, you must conduct fuel analyses either according to §63.7521 and follow the procedures in paragraphs (c)(1) through (5) (4) of this section or according to the procedures in §63.7540(c) .

****

§63.7540(c) In lieu of demonstrating initial compliance with the applicable HCl and/or mercury emission limit following the method in §63.7530 and in lieu of demonstrating continuous compliance with the applicable HCl and/or mercury emission limit following

Eastman Boiler MACT Comments Page 29 of 45 the method in paragraph (a) of this section, you may follow the method specified in paragraphs (c)(1) through (2) of this section.

(1)Site-specific fuel analysis plan. You must follow the requirements of §63.7521(b). In addition, you must specify in the plan the frequency with which you will determine mercury and/or chlorine content in each fuel.

(2) Compliance with mercury and/or chlorine feedrate limits. To comply with the applicable feedrate limits of §63.7530, you must monitor and record mercury and/or chlorine feedrates as follows:

(i) Determine and record the value of the parameter for each fuel following the site-specific fuel analysis plan developed following paragraph (c)(1) of this section.

(ii) Determine and record the mass or volume flowrate of each fuel for each operating hour using a continuous monitoring system. If you determine flowrate of a fuel by volume, you must determine and record the density of the fuel by sampling and analysis (unless you report the constituent concentration in units of weight per unit volume (e.g., mg/l)); and

(iii) Calculate and record the mercury and/or chlorine feedrate for each operating hour using Equation A.

o o ee e) i i)) i i) Equation A

Where:

Hourly Pollutant Feedrate (HPF) = mercury or chlorine feedrate to the boiler or process heater in units of pounds per million Btu heat input for each operating hour.

Ci = percent by weight mercury or chlorine concentration for fuel type, i, for the operating hour as determined using the fuel analysis plan developed according to paragraph (c)(1) of this section.

Mi = mass of fuel type, i, in units of pounds for the operating hour as determined according to paragraph (c)(2)(ii) of this section.

HVi = heating value for fuel type, i, in units of Btu per pound for the operating hour as determined using the fuel analysis plan developed according to paragraph (c)(1) of this section.

n = Number of different fuel types burned in your boiler or process heater during the operating hour.

(iv) At the end of each calendar month, calculate and record the twelve

month rolling average mercury and/or the HCl feedrate for your boiler or process heater using Equation B.

we e o o i e e o ee e)) Equation B
Where:
Hourly Pollutant Feedrate (HPF) = mercury or chlorine feedrate to the boiler or process heater in units of pounds per million Btu heat input for each operating hour as determined according to paragraph (c)(2)(iii) of this section.
n = number of operating hours during the past 12 months.

Response: 40 CFR § 60.8(b) provides authority for alternative performance testing under NSPS . This authority can be used to develop alternative compliance strategies as the commenter requests. In like measure, a facility owner or operator may seek relief from retesting under these authorities. The Agency would review the proposed alternatives on a case by case basis, to include the reduction in testing frequency associated with low hazard fuels.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 121

Comment: AF&PA supports the concept of allowing sources burning fuels with low mercury or chlorine content to avoid installing expensive, unneeded control equipment. However, we find the testing, monitoring, record-keeping and reporting requirements to be not only excessively burdensome, but simply unworkable for boilers burning wood, wood residuals, other biomass fuels, or a combination of solid fuels – practices that are very common in our industry. AF&PA's members operate multi-fuel, or combination, boilers that may burn four or more fuels during a given year, month, or week, including, but not limited to, wood, bark, other wood residuals (chips, knots, or sawdust, for example), panel plant trim, sludge, tire-derived fuel, coal, oil, and natural gas. Many of these boilers rely on wood, bark, and wood residuals as their primary fuel. Defining worst-case fuels and requiring mills to retest their multi-fuel boiler fuel mixes whenever they change suppliers will present enormous, and perhaps insurmountable, logistical problems. Mills relying heavily on wood, bark, or wood residuals may receive shipments from as many as 100 suppliers/woodlots a month, raising the likelihood of constant fuel sampling, retesting and, quite possibly, frequent performance testing. Some mills are receiving logs from foreign locations. AF&PA believes EPA's proposed testing, monitoring, record-keeping and reporting approach is unworkable for these types of units and EPA should not require mills to analyze biomass fuels obtained from each and every supplier.

Response: See response to comment EPA-HQ-OAR-2002-0058-2805.1, excerpt 8 for the definition of fuel type as it relates to biomass. According to the definition of fuel type, a change in fuel supplier in and of itself does not necessitate retesting.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 126

Comment: While this compliance approach may be easy to manage for some sources, especially ones with very stable fuel supply and usage, it may be very cumbersome and burdensome for other sources with variable fuel suppliers and fuel mixes. This approach involves a great deal of recordkeeping and potentially subjects the source to frequent testing requirements if fuel content varies, regardless of the margin of compliance shown during the initial performance test. Under the proposed rule, even if a unit is operating at 50 percent of the applicable emission limit, the facility would be required to re-test if the fuel chloride input increases 1 percent over the level achieved during the initial performance test.

A more appropriate approach is to allow the source to set operating parameters at levels that generate emissions at the emission limits established in the rule. This is the only approach which meets the requirements of the Act, since it is the only approach that does not impose a beyond the floor limit which has not been justified per the requirements of 112(d). Under this approach, the source would simply do the performance test using its normal fuel mix, determine operating conditions that show compliance and then adjust those conditions, using engineering calculations to assure it would meet the emissions standards established in Table 1 or 2. If the initial performance test shows emissions at 50 percent of the standard at a particular mercury or chloride fuel input, the fuel input limits should be set at a level higher than the performance test values, taking into account control device operating parameters as appropriate. This approach would be environmentally beneficial and would greatly reduce burdens. It is the only practical way to establish fuel input operating limits.

Compliance could also be demonstrated through the use of fuel purchase specifications. Sources would determine from the performance test a maximum fuel pollutant concentration at which the emissions limitations are achieved. For instance, the performance test may demonstrate that fuels containing chlorine in concentrations less than x Ib CI/MMBtu allow the source to comply with emissions limitations. A facility should be allowed to extrapolate an allowable fuel input based on a comparison of performance test conditions to the applicable emission limit. The source would then set a fuel specification of x Ib CI/MMBtu and would be allowed to burn any fuel of the same general type (e.g., solid, liquid, or gas) as long as it met this specification. Sources could require that the fuel supplier provide periodic certification that the fuel meets the specification, based on analysis, or could establish an internal sampling and analysis program for that purpose. In any case, where common fuels are utilized in more than one unit, common fuel quality data would be maintained and considered applicable to all such units. Continuous compliance could also be demonstrated through ongoing fuel analysis.

As an example, sources would (1) establish a fuel input limit (e.g., Ib Cl/MMBtu) based on the compliance test as described in the proposal (with an allowance for extrapolation); (2) periodically sample and analyze each fuel for constituent concentration and heating value according to a specified sampling and analysis plan; (3) monitor the daily usage of each fuel; (4) calculate the average total daily constituent input (lb/MMBTU) accounting for all fuels fed; and (5) demonstrate that the average daily constituent input rate averaged over each month of operation does not exceed the operating limit. This option would afford the source the opportunity to vary fuel mixes, while still insuring that protective operating limits are met.

Given the wide variety of sources impacted by this proposal, it is reasonable to provide flexibility in how sources demonstrate compliance, as long as clearly-defined compliance objectives are met. AF&PA requests that EPA include the compliance approaches discussed above in the final rule as allowable optional compliance strategies. We are willing to work with the agency to further refine these strategies. Additionally, AF&PA requests that the final rule include an allowance for a source to use, with prior Agency approval, other compliance strategies that may be more appropriate on a site-specific basis.

Response: 40 CFR § 60.8(b) provides authority for alternative performance testing under NSPS . This authority can be used to develop alternative compliance strategies as the commenter requests. In like measure, a facility owner or operator may seek relief from retesting under these authorities. The Agency would review the proposed alternatives on a case by case basis, to include the reduction in testing frequency associated with low hazard fuels. For example, sources can also submit a fuel monitoring alternative for approval in their fuel monitoring plan to establish an operating limit based on extrapolation from the fuel content used during the initial compliance test and the applicable emission limit for that source.

Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 275

Comment: A regulatory mandate to switch from solid fuels to natural gas, while aimed at reducing emissions from coal, would have the unintended effect of substantially curtailing the viability of burning biomass fuels. Forest product mill industrial boilers often co-fire coal with biomass residuals (e.g., bark, wood chips, rejected fiber, knots, and/or non-recyclable fiber) and get more than 60% of their energy needs from biomass-based fuels. Smaller wood products boilers may burn only biomass residual materials. However, as EPA has recognized, boilers configured for a certain physical phase (i.e,. solid, liquid, or gas) fuel in most cases would not be able to operate using a different-phase fuel.
The limitation the proposed rules would engender on the ability of facilities to use biomass for fuel is at odds with other environmental goals. From pollution prevention, climate change, and fossil resource conservation perspectives, as well as to ensure full utilization of biomass materials, the burning of wood products residuals (that have no other commercial utility) should be encouraged as good public policy. Doing so utilizes wood residuals for their fuel value, conserving valuable landfill space and avoiding unnecessary fossil fuel consumption. Moreover, an executive order entitled “Developing and Promoting Biobased Products and Bioenergy” notes the significant environmental benefits of enhanced utilization of biomass, including using biomass for energy. See Executive Order 13134, 64 Fed. Reg. 44638 (August 16, 1999). These benefits include: “the potential to reduce our Nation’s dependence on foreign oil, improve air quality, water quality, and flood control, decrease erosion, and help minimize net production of

greenhouse gases." Id. at 44639. Significantly, unlike coal and natural gas, biomass is not a fossil fuel, so that energy generated from biomass does not result in a net release of greenhouse gases to the atmosphere. In light of the detrimental effect of fuel switching on biomass fuel, EPA properly rejected this option in setting the MACT floors.

Response: EPA thanks the commenter for their input and has retained is position of rejecting fuel switching as a MACT floor option.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)

Comment: Fuel sampling should not be required for each new fuel supplier.
Pulp and paper mills burning biomass have a large number of biomass suppliers and hundreds of trucks deliver biomass fuel to the facility in a day. The rule should simply require a representative sample of biomass from the fuel pile. This comment is also relevant to facilities burning coal. The rule should require one sample per coal type (e.g., bituminous versus sub-bituminous) not one sample per coal supplier.

Response: Fuel sampling when you switch fuel suppliers is only required if that supplier's fuel is a different fuel type or mixture than what was burned during the performance test. EPA believes that requiring a fuel analysis for each new fuel is reasonable and necessary for assuring compliance with the standards. The fuel sampling methodology in the proposed rule at 63.7521 specifies the means for obtaining a representative sample.

Commenter Name: Randall D. Quintrell
Commenter Affiliation: Georgia Paper and Forest Products Association, GPFPA
Document Control Number: EPA-HQ-OAR-2002-0058-2905
Comment Excerpt Number: 18

Comment: GP&FPA operates a variety of boiler types and have many combination fuel or multi-fuel boilers. The performance testing requirements in the proposed Rule for a multi-fuel boiler are somewhat unclear at best and unachievable at worst. For one, the testing provisions in 40 CFR 63.7520(c) use undefined terms that create confusion. These include: "maximum normal operating load"; and "mixture of fuels that has the highest content of chlorine and mercury".

For example, one mill operates an existing unit that would be classified as a "designed to burn biomass" unit because on an annual basis, the heat input capacity of coal is less than 10%. However, on a short-term basis, the unit is capable of combusting 100% coal. As the coal potentially has the highest levels of HC1 and Hg, would the mill be required to test this unit at 100% coal or other very high atypical usage rate and compare those emissions to the limitations for boilers designed to burn biomass, which is its official classification? With such extended test runs, this would be extremely expensive even if a stable fuel supply could be maintained for such a duration at all. Also the biomass limits for Hg and HC1 would be impossible to meet at high rates of coal firing - that is why there are separate subcategories in the first place. We believe that EPA's intent for such units is for them to test using a fuel mix that is representative of typical operations, but that is not clearly specified in the proposal and the language could be interpreted otherwise. The final Rule needs to address multi-fuel boiler situations such as this both from an emissions limitation standpoint and from a testing standpoint. EPA must revise the testing criteria discussed above to give more consideration to the reality of the challenges involved in conducting performance tests on multi-fuel boilers and provide more specific input as to the expectations for such performance testing.

Response: See response to comment EPA-HQ-OAR-2002-0058-2723.1, excerpt 73 for clarified intent.

Comment: It is not possible to set maximum fuel inlet operating limits based on a single annual test, particularly for fuels which naturally vary over the course of a year. An annual test that is "representative" of the fuel should be adequate, and not require setting fuel inlet operating limits. This is particularly for biomass-fired sources, where the fuel content will not vary greatly over a year.

Response: The maximum input levels for chlorine and mercury determined from equations 7 & 8, respectively, are not operating limits but are rather levels which can be used to provide an indication of whether a fuel switch may affect the source's compliance status.

Comment: Gas- and liquid-fired boilers and process heaters can often change fuels with little or no equipment modification. For instance, units with both liquid and gas capability can move from gas to liquid with simple fuel realignments. Units that fire gas can move between the Gas 1 and Gas 2 subcategories simply because site fuels are mixed differently or because operating rates or fuel gas production changes result in changes to the site fuel gas/natural gas balance. For this reason, among others, we believe there should only be one gas subcategory, and we discuss that recommendation in section IV.D of these comments.

If two gas subcategories are maintained and the proposal work practice and emission limit proposals are adopted, the common situation of a unit moving from the Gas 1 subcategory to the Gas 2 subcategory and the reverse must be addressed. Additionally, the definitions of these two subcategories must be made consistent. We recommend that if a unit moves between Gas 1 and Gas 2, the unit have up to three years to transition from the Gas 1 requirements to the Gas 2 requirements. This is necessary because these transitions are often not planned but occur because of changes in available gases due to varying operating rates of particular processes, addition of new steam or fuel producers or consumers or changes in feedstocks that yield different amounts of fuel gas from a particular process. Thus, if a Gas 1 unit fires more than 10% Gas 2 in a calendar year, it must have three years to re-permit [Footnote: Permitting is an issue because Title V permits will have to include the requirements from subpart DDDD for the particular subcategory that applies to that boiler or process heater.] the unit and to meet the extensive Gas 2 requirements. If a Gas 2 unit fires more than 90% Gas 1 in a year it should have whatever time it takes to re-permit the unit to transition to the Gas 1 requirements.

The movement of a unit from a gas subcategory to the liquid subcategory and vice versa must also be addressed. This can happen because of changes in fuel economics but, more typically, would happen because liquid firing exceeds 10% in a calendar year for a particular unit because of gas supply problems or extended fuel gas imbalances. In this case, we also request three years be allowed for the unit to re-permit and to comply with the new set of requirements.

The situation of a boiler or process unit opting to change from Gas 2 or liquid fuel to Gas 1 prior to the compliance date of this rule also needs to be addressed, but that situation would only need additional compliance time if emission limits are imposed for Gas 1.

Recommendation: Allow three years for compliance for units that move from the Gas 1 subcategory to the Gas 2 subcategory or units that move from a gas subcategory to the liquid subcategory.

Response: &&&
ISSUES TO ADDRESS: 1. WILL WE BE REVISING THE GAS 1 & 2 SUBCATEGORIES; 2. HOW MUCH TIME WILL BE GRANTED FOR SOURCES TO COME INTO COMPLIANCE WITH A NEW SUBCATEGORY; 3. CAN COMPLIANCE BE DELAYED UNTIL REPERMITTING UNDER TITLE V

PROPOSED POSITION FOR 2 & 3. THIS LANGUAGE NEEDS TO BE FINESSED BY OAQPS AND OGC -- THIS IS JUST TO GET US GOING:

Sources may switch fuels and therefore switch subcategories, however it must be done in a way that does not create delays in compliance, impede our ability to determine compliance with the initially /previously applicable standards, or allow for large periods of time during which the compliance status of the facility is unknown. As a threshold matter, since several compliance options for the rule allow annual averaging, sources may not switch between fuel subcategories more frequently than once per year.

The Clean Air Act requires that EPA establish a compliance date or dates for each category or subcategory of existing sources which shall provide for compliance in no event later than three years after the effective date of the standard. As such, EPA is not granting an additional three years each time a source decides to switch fuels and becomes subject to a different subcategory. EPA expects that sources that wish to switch fuels will plan for the fuel switch and will be in compliance as of the date that the source becomes subject to the new subcategory. The only compliance extension available would be a case-by-case determination as to whether up to one additional year is necessary for the installation of controls, as allowed in CAA Section 112(i)(3)(B). NEED TO CHECK WITH OGC IF THIS IS EVEN AVAILABLE IF THE RULE HAS ALREADY BEEN EFFECTIVE FOR 4 YEARS.

Extending the compliance deadline to allow additional time for repermitting is not appropriate since the permit is designed to reflect the applicable requirements of the underlying regulations, not to delay effectiveness of applicable requirements and pollution controls.

The final rule clarifies that sources must remain in a given subcategory for a period of at least 12 months after the initial compliance test that demonstartes compliance with all the standards. Initial testing to demonstrate compliance with a new subcategory after a fuel switch must be completed within 90 days of the date upon which the source has identified via notification to the Agency that a subcategory switch will occur. Since the source will have already been operational and subject to the Boiler MACT for over a year, EPA believes that 90 days is sufficient time for the facility to familiarize itself with its new combustion practices and controls, schedule the test, and provide the 60 days advance notification.

Comment: §63.7540(a)(2) states that records of type and amount of fuel are required to demonstrate that the fuel has lower fuel input for mercury and HC1 than the maximum values calculated during the last performance tests "(if you demonstrated compliance through performance stack testing)." Does this apply only to sources that demonstrated compliance through stack testing without using control devices or does it apply to everyone stack testing irrespective of control devices?

Response: The requirement in 63.7540(a)(2) to keep records on the type and amount of fuels burned applies to all affected sources irrespective of how compliance is demonstrated and achieved.

Commenter Name: Donald R. Schregardus
Commenter Affiliation: Department of Defense

Comment Excerpt Number: 27

Comment: §63.7530(b) requires calculation of the maximum chlorine input level using equation seven (7) and the maximum mercury input level using equation eight (8) "if you demonstrate compliance through performance stack testing." This maximum fuel input level calculation is based on the average values of mercury and chlorine derived from fuel samples taken during the stack test. §63.7540(a)(2) requires continuous compliance with these maximum fuel input levels. Because these maximums levels are calculated from average values, it is impossible to continuously assure compliance with this provision because the formulas do not take into account the normal variability of the mercury and chlorine content of the fuel. Does the provision to calculate maximum fuel input levels only apply to those sources that burn more than one type of fuel simultaneously?

Response: The input levels for chlorine and mercury determined from equations 7 & 8, respectively, are not operating limits but are rather levels which can be used to provide an indication of whether a change in fuels may have affected the source's compliance status. The provision to calculate maximum fuel input levels applies to any source that opts to determine compliance with the HCl and mercury limits using stack testing.

Comment: One DoD facility burns only coal in their solid fuel boilers. Are they required to conduct monthly fuel analysis for mercury and chlorine content to demonstrate continuous compliance with a maximum chlorine content level determined by equation 7 and a maximum mercury content level determined with equation 8? If so, it is impossible to continuously comply with this requirement because it is impossible for a coal supplier to guarantee that all coal supplied from a coal seam will be less than the average value of mercury and chlorine content from that same seam. Does EPA expect sources to test with coal having ultra-high levels of mercury and chlorine? How does EPA propose locating special test coal? Does EPA endorse the use of special test coal for compliance demonstrations? How can EPA justify establishing a maximum value limitation from the average of the fuel group when the fuel group itself is what is normally burned?

Response: The chlorine and mercury input levels are not limitations, but are rather levels used to evaluate whether a fuel switch may affect the source's ability to comply with the standard. For sources that opt to demonstrate compliance using stack tests instead of fuel analysis, you must recalculate the maximum chlorine and mercury input if you plan to burn a new fuel, a fuel from a new mixture, or a new supplier's fuel that differs from what was burned during the initial performance tests based on supplier data or own fuel analysis using the methodology specified in Table 6 of this proposed rule. Although the preamble to the rule explained this process, we are making some corrections and clarifications to § 63.7530(b) and § 63.7540(a)(4) to reference the method for determining chlorine and mercury input, and to correct cross-references and the equation numbers for determining the maximum input levels (6 and 7).

EPA expects that sources will test, consistent with 63.7520(c), under conditions that will demonstrate the source's ability to continuously comply with the emissions limits when operating under expected operating conditions. If a stack test does not represent the range of combined process and control measure conditions under which the facility expects to operate, the delegated agency may determine that retesting is warranted.
See response to comment EPA-HQ-OAR-2002-0058-2763.1, excerpt 28 for discussion of maximum chlorine and mercury input.

Comment Excerpt Number: 29

Comment: DoD facility stack test example maximum content calculation: Stack Test #1 Fuel Analysis Content Results
Run #1 Hg = 2.14 x 10-61b/MMBtu Cl = 0.128 lb/MMBtu
Run #2 Hg = 6.52 x 10-61b/MMBtu Cl = 0.105 lb/MMBtu
Run #3 Hg = 1.46 x 10-6 lb/MMBtu Cl = 0.139 lb/MMBtu
Average and Max. Content Limitation Hg = 3.37 x 10-6 lb/MMBtu CI = 0.124 lb/MMBtu

Stack Test #2 Fuel Analysis Content Results
Run #1 Hg = 3.57 x 10.6 lb/MMBtu Cl = 0.106 lb/MMBtu
Run #2 Hg = 1.42 x 10-6 lb/MMBtu Cl = 0.114 lb/MMBtu
Run #3 Hg = 2.13 x 10-6 lb/MMBtu Cl = 0.106 lb/MMBtu
Average and Max. Content Limitation Hg = 2.37 x 10-6 lb/MMBtu Cl = 0.109 lb/MMBtu

Depending on which maximum content limitation would be established from stack testing coal analysis results, this facility expects to be out of compliance with both the maximum mercury and maximum chlorine content limitations between 33 and 66 percent of the time if an individual test run were representative of one month's coal analysis data. Thus, the requirement to use equations 7 and 8 as written is impossible to comply with under normal boiler operations and typical fuel analysis results.

Response: The input levels for chlorine and mercury determined from equations 7 & 8, respectively, are not operating limits but are rather levels which can be used to provide an indication of whether a change in fuels may have affected the source's compliance status. The standard sets operating limits for control device operating parameters which must be complied with on a continuous basis.

Comment: Facilities should not be required to perform fuel analysis for each supplier – there may be a number of suppliers for coal and biomass. Biomass in particular does not vary greatly, such that individual supplier analysis is not justified.

For biomass, the fuel input limitation should not be based solely on the initial performance test, because natural variations in the biomass may cause later deviations from the limit. Sources should be allowed to demonstrate the control efficiency (based on measuring fuel input and stack emissions) during the initial performance test, and utilize this efficiency to determine the maximum fuel input limits for chlorine, mercury and total selected metals (assuming TSM is included in the final rule) allowable in order not to exceed the emission limits.

Response: See response to comment EPA-HQ-OAR-2002-0058-2805.1, excerpt 8 for the definition of fuel type as it relates to biomass. According to the definition of fuel type, a change in fuel supplier in and of itself does not necessitate retesting. See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for flexibility in exceeding the maximum fuel input.

Comment: Units Cannot Obtain the Worst Case Fuel During Emissions Testing.
The Proposed Rule requires that units required to demonstrate compliance via stack testing must conduct fuel analysis to establish maximum fuel pollutant input levels. 75 FR 32057. This "worst-case fuel" requirement is unreasonable. EPA's theory apparently is that the owner or operator will be able to procure a worst-case fuel that will maximize the fuel chlorine, mercury and/or total selected metals content without exceeding the Emission Limitation in Table 1. In

fact, EPA suggests in §63.7520 that the owner or operator may have to conduct more than one performance test to accomplish this. The iterative process by which an owner or operator must search for fuels and then conduct performance tests until the worst-case fuel is found will be very time consuming and expensive and is unnecessary.

The same result can be accomplished by requiring the owner or operator to perform the initial performance test using the same fuel that has typically been fired in each boiler. The results of the performance test can then be used to prorate the actual chlorine, mercury and/or total selected metals content of the fuel to the worst-case conditions that would meet the emission limits. The owner or operator would then simply have to maintain the fuel chlorine, mercury and/or total selected metals content below the prorated values established during initial performance test, regardless of the fuel supplier. A new performance test could then be required if the fuel chlorine, mercury, and/or total selected metals content exceeded the prorated values established during the performance test.

Response: See response to comments EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 and EPA-HQ-OAR-2002-0058-2763.1, excerpt 28 for discussion of maximum chlorine and mercury input.

Comment: C. Fuel Quality Limits Should Not Be Established Based on Quality During Initial Performance Test.
Under the Proposed Rule, fuel quality limits are established based on quality during the initial performance test. This approach is unreasonable and does not take into account the inherent variability of fuels. EPA should allow units to establish an operating limit based on extrapolation from fuel content correlated with emissions test data up to the emission limit. Further, EPA should allow units that choose to comply with emissions standards by continuous monitoring (e.g. Mercury CEMS) to avoid setting a fuel quality limit for that monitored constituent, given that continuous monitoring would ensure greater confidence that actual stack emissions are within acceptable limits. Additionally, EPA should allow units to conduct fuel supplier sampling and/or analysis and on-site sampling on a monthly composite sample basis. On-site sampling standards could be established similar to those found in the original MACT rule. The standards contained in that rule included processes for collecting samples and statistical analysis of fuel.

While on-site sampling is appropriate for some units, it is not appropriate for others. Specifically, biomass and some coal units often have large numbers of suppliers and sampling could be burdensome if applied to every new supplier. Therefore, EPA should provide that biomass units need only one representative sample from the fuel pile and that coal units obtain one sample per coal type, not per supplier.

Additionally, according to the Proposed Rule, units that burn a Gas 1 gas in combination with other fuel types do not have to conduct monthly sampling/analysis of the Gas 1 gas under any circumstances. However, it appears that units classified in categories other than a Gas 1 unit are required to routinely sample/analyze all fuel types burned in the unit. This would include non-Gas 1 units that burn some amount of natural gas and refinery gas. Such a requirement would be unreasonable. First, natural gas suppliers generally do not perform a broad spectrum of analysis of the gas supplied. Furthermore, there are only a handful of laboratories in the United States that are capable of conducting analysis of pipeline natural gas. Simply put, the routine analysis of pipeline natural gas would be a complicated process and it should be specifically noted to not be required.

Response: If a source opts to use an alternative monitoring technique, they can submit a monitoring alternative for approval with their site-specific monitoring plan which outlines the use of mercury CEMS, and related performance specification and quality assurance mechanisms. Sources can also submit a fuel monitoring alternative for approval in their fuel monitoring plan to establish an operating limit based on extrapolation from the fuel content used during the initial compliance test and the applicable emission limit for that source.

Comment Excerpt Number: 99

Comment: Table 8 Item 7 specifies that you may “Only [burn] the fuel types and fuel mixtures used to demonstrate compliance with the applicable emission limit according to 63.7530(c) or (d) as applicable.” Requiring sources to burn only the specific fuel or fuel mixture that was used during testing is a practical impossibility and, furthermore, it makes no sense to require sources to generate the maximum possible Hg and Cl- emissions at all times. That is certainly not the intent of this requirement and the massive increase in Hg and Cl- emissions it would engender is certainly not reflected in the record.

Recommendation: To make this requirement workable, this requirement needs to be reworded as follows “Only [burn] fuel types and fuel mixtures containing less Hg and Cl- than the fuel or fuel mixture used to demonstrate compliance with the applicable emission limit according to 63.7530(c) or (d), as applicable.”

Response:EPA appreciates the commentor's careful review of the language in the table. The intent of the provision in Table 8, item 7.a. is to confirm that sources must not burn fuels that were not evaluated consistent with the compliance procedures in 63.7530. Any new fuel or new fuel mixture must be subject to a fuel analysis, and, if compliance with HCl and mercury limits is determined via stack tests, the chlorine and mercury inputs of the new fuel must be compared to the maximum chlorine and mercury input levels of the fuel type that was used in the stack test.

As such, sources must continue to burn the fuel types and fuel mixtures that were the basis of their compliance determination, until such time as they demonstrate that a new fuel will also meet the standards. Therefore we are not revising this portion of the language in Item 7.a. However, we note that the reference to 63.7530(d) is incorrect. The correct citations for the compliance determination procedures are 63.7530(b) or (c).

Comment: Additional Options For Compliance Demonstration.
While this compliance scheme may be appropriate for some sources, especially ones with very stable fuel supply and usage, it may be very cumbersome and burdensome for other sources. It involves a great deal of recordkeeping and potentially subjects the source to frequent testing requirements. As an example of the complexity this proposed compliance plan involves, Section 63.7550 (c)(4) requires that among other things, the semi annual report is to have "the supplier of the fuel and original source of the fuel." To make the proposed compliance plan work (which CIBO does not believe can be done), the Agency would have to be much more explicit for instance in its definition of the original source of the fuel. And that definition would need to consider as many contexts as exist in the market for fuel generation, distribution, and delivery; e.g., if the fuel is a process fuel generated internally, if the fuel is from a distributor or supplier, and if the fuel is pulled from commercial pipelines that may receive input from numerous companies in varying amounts over rime." It appears that the objective for the operating limits that are based on fuel analysis is to insure that the pollutant (chlorine, metals, mercury) input to the source for a given level of operation does not exceed the input level demonstrated during the performance test, where compliance with emissions limitations and work practice standards was demonstrated.

Response: The supplier normally has fuel quality information and can identify the previous link in the chain of supply. The purpose for this requirement is to ensure the Agency has the ability to determine the content of the fuel as delivered, if the facility did not itself test the fuel. The purpose for including the term "origin" is to specify the supply chain terminus so that the Agency can validate fuel content, if necessary for enforcement purposes.

Comment Excerpt Number: 155

Comment: There are several ways in which this objective can be achieved, in addition to the single compliance method proposed. As an example, compliance could be demonstrated through the use of fuel purchase specifications. Sources would determine from the performance test a maximum fuel pollutant concentration at which the emissions limitations and work practice standards are achieved. For instance, the performance test may demonstrate that fuels containing chlorine in concentrations less than x IbCI/MMBTU allow the source to comply with emissions limitations. The source would then set a fuel specification of x IbCI/MMBTU and would be allowed to burn any fuel of the same general type (e.g., solid, liquid or gas) as long as it met this specification. Sources could require that the fuel supplier provide periodic certification that the fuel meets the specification, based on analysis, or could establish an internal sampling and analysis program for that purpose. In any case, where common fuels are utilized in more than one unit, common fuel quality data should be maintained and considered applicable to all such units. Continuous compliance could also be demonstrated through ongoing fuel analysis according to applicable Equations 1, 2 or 3 in § 63.7530.

As an example, sources would (1) establish a fuel input limit (e.g., IbCl/MMBTU) based on the compliance test as described in the proposal (with an allowance for extrapolation as proposed by CIBO elsewhere in these comments); (2) periodically sample and analyze each fuel for constituent concentration and heating value according to a specified sampling and analysis plan; (3) monitor the daily usage of each fuel; (4) calculate the average total daily constituent input (lb/MMBTU) accounting for all wastes fed; and (5) demonstrate that the average daily constituent input rate averaged over each month of operation does not exceed the operating limit. This option would afford the source the opportunity to vary fuel mixes, while still insuring that protective operating limits are met.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for flexibility in exceeding the maximum fuel input and the use of fuel purchase specifications.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 169

Comment: Proposed 63.7525(c) also requires that stack tests be performed at maximum normal operating load while burning the type of fuel or mixture of fuels that have the highest content of mercury and chlorine. It is impossible to operate a boiler at precisely the maximum normal operating load or the highest content of chloride and mercury. If these requirements are maintained, both of them should be reworded to require the test be performed at or near the maximum operating load and chloride and mercury level. This would make these requirements feasible and comport with normal stack testing practice, where operation of a combustion source at between 80 and 100% of design capacity is typically considered representative of maximum normal operation for performance test purposes.

Response: The meaning of the term is sufficiently clear. To use more ambiguous language would simply open the door to reduced heat rates and lower than likely emissions during testing. The language as written is sufficient.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 171

Comment: The requirement for doing performance tests at maximum chloride and mercury applies even if testing for chloride and mercury is waived under the provisions of proposed 63.7515(b)-(d) or because fuel testing will be used. There is certainly no purpose in increasing chloride and mercury emissions when not performance testing for these species. Thus, the requirement to performance test at maximum chloride and mercury levels in 63.7515(c) should also be waived if performance tests are not being done for those species.

Recommendation: Revise 63.7515(c) to waive the requirement to test at maximum chloride and mercury levels if these pollutants are not being measured in a particular performance test.

Response: Because we specifically either test of Cl and Hg or specifically waive the duty to do so as a result of good performance, there is not a reason to burden other tests with this particular requirement. We have added a waiver to section 63.7515(c) of the final rule.

Comment: Proposed 63.7515(f) calls for monthly fuel monitoring for Hg and Cl-, if you opt to use fuel analysis to show compliance. It states If you burn a new type of fuel, you must conduct a fuel analysis before burning the new type of fuel in your boiler or process heater. As discussed in our previous comment, testing every stream is not possible for the very common blended fuel gas systems and there certainly is no way to test every startup, shutdown, malfunction or maintenance gas stream prior to mixing it into the blended gas stream.

Recommendation: In 63.7515(f), it should be made clear that requirement does not apply to adding or removing streams from a blended fuel gas system or changing the relative proportions of streams mixed into those fuel gas systems.

Response: The fuel mix should never result in any greater Cl or Hg emissions than as tested. This should be determinable by simple arithmatic associated with the content of the components to the fuels stream. The facility should have sufficient records to document their actual fuels mix would not be expected to emit pollutants at greater than found in the performance test. These calculations should be kept as part of the fuels recordkeeping and would suffice to meet the requirements of the rule. The rule as also added certain provisions to exempt units that serve as control devices for other MACT regulated exhaust streams, and has modified the definitions of gas 1 and gas 2 subcategories which should also reduce the concerns for the commenter.

Comment: Having said that, we are very concerned about the particular method of accounting for variability employed by the Agency in the proposal. EPA proposes to account for both "within test" and "between test" variability by calculating the 99% upper prediction level of the available and relevant emissions testing data. See, e.g., id. at 72976-7.

In concept, such an approach makes sense because setting the floor at the 99% upper prediction limit ostensibly would cause the floor to encompass virtually the entire range of emissions reasonably expected by the better performing sources from which the data were derived if the data encompassed all variations that can impact those emissions and the emissions test/fuel quality data were truly random throughout the population. In practice, however, this approach is flawed because the underlying data are not, in fact, representative of the range of expected operations and true variability that reasonably should be expected from the better performers. The reason is that the emissions data relied upon in the proposal were produced during reference method performance testing under very limited operating conditions, and with a very limited variation in potential fuel quality.

Performance testing is required to be conducted under "representative operating conditions." See 40 C.F.R. § 60.55c(b)(1). The rules do not define the term "representative operating conditions." However, EPA’s National Stack Testing Guidance suggests that such conditions: (1) represent the range of conditions under which the facility expects to operate (regardless of the frequency of the conditions); and (2) are likely to most challenge the emissions control measures of the facility (but without creating an unsafe condition). Clean Air Act National Stack Testing Guidance at 14. This guidance further defines "representative" as "normal" as it states that "The MACT program further defines representative performance as normal operating conditions" and again when describing the performances test conditions as described above to be "under. .those representative (normal) conditions. .." Id. Of course, as expressly stated in the document itself, the National Stack Testing Guidance is "intended solely as guidance" and, as such, "is not a regulation." Id. at 2.

Properly conducted, performance tests are, indeed, a reliable measure of compliance at a given point in time with the relevant standard. However, such tests typically should not be expected to reveal the true range of variability in operating conditions because sources strive to maintain rigorous, yet consistent, operating conditions during tests, between testing runs within a given testing session, and between testing sessions. As indicated by the Stack Testing Guidance, the goal of performance testing is to challenge the applicable control device or control measure to assure that compliance will be maintained under rigorous conditions. Variable operations during testing are inconsistent with the purpose and intent of such testing. In addition, some reference method tests are most applicable for use under steady state conditions.

Moreover, while owners and operators may seek to conduct testing at reasonable worst case conditions to assure compliance during less rigorous conditions, it is entirely possible that operations during less rigorous conditions could nevertheless accommodate operational variation that would not threaten compliance with the standard, but could be relevant when the data are used to set standards on a pollutant-specific basis rather than a unit-specific basis. As a hypothetical example, the most rigorous testing condition for HCl emissions from a given boiler might be a fuel with high halide content. Thus, it would be logical for testing to be performed under these conditions. However, other HAP constituents in the fuel – such as metals – would not necessarily be at "worst case" levels during testing focused on halides. In this scenario, the testing might show extremely low levels of metals emissions, which would not necessarily reflect higher levels of such emissions that might occur during normal operations. It is also typically not feasible to actually obtain "worst case" fuel quality for emissions testing purposes simply due to natural variability in fuel quality, especially coal.

In order to address these limitations, CIBO recommends that EPA utilize a site specific fuel analysis plan approach and correlate fuel quality during emissions testing to emissions measured, and then use ongoing fuel analysis on an appropriate time basis to determine ongoing compliance based on emissions control performance achieved during the emission test. For example, some existing coal fired units might be conducting daily coal sampling and analysis for sulfur and HHV, so accumulating the individual coal samples for a month and preparing a monthly composite for HHV, S, Cl, and Hg analysis would allow determination of projected emissions over that month for the operational boilers. In that way, a 12 month rolling average emission rate could be determined relative to the emission limit. This approach would then allow use of actual fuel quality during the emissions test to not become an artificial limit to operation of the units, while still assuring emissions comply with the limits.

Response: The rule does not define representative operating load conditions but the final rule has modified the requirements in Table 8 to ensure that the boiler load does not exceed 12-hour block average load does not exceed the load of the performance test. It is expected that sources will test at conditions that will not affect their ability to operate at the loads necessary to sustain their processes. See response to EPA-HQ-OAR-2002-0058-2845.1, excerpt 34 for recognition that worst-case for one parameter may not be worst-case for another parameter. See response to comment excerpt EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for discussion of a plan to incorporate a site-specific fuel analysis monitoring plan.

Comment: It appears that in an effort to provide boiler and process heater operators with the flexibility to select from a menu of available fuels, EPA has fashioned a system where the emission limit for a boiler burning multiple fuels will be determined after the fuel is combusted, by looking back to calculate whether the boiler exceeded the "designed to combust" threshold for coal or biomass or liquid fuel. The proportions or types of fuels combusted during a 12-month operating period may or may not align with those combusted during the performance test.

In the current proposed subject rule, EPA has made an effort to define reasonable subcategories based on the fuel burned, resulting in four primary groups, coal-fired, biomass-fired, liquid-fired, and gas-fired units. Within these groups are the boiler subcategories, based on equipment design. To define the MACT floor, the best approach is to review the results of performance tests conducted during actual operation of a specific type of boiler burning a specific type of fuel. EPA has taken this approach to define the MACT floors. However, to determine which limit is applicable to a specific boiler, EPA appears to have defined the subcategories based on what fuel a boiler is "designed to combust" rather than actual operation. This change from the approach proposed in the 2004 MACT rule (40 CFR 63.7530) to address fuel mixtures used in boilers and process heaters is not necessary. We recommend that EPA should establish MACT limits for each major category of fuels and require compliance verification for use of multiple fuels using the methods found at 40 CFR 63.7530.

Response: Please see the preamble for discussion of combination fuel units which will help mitigate the concerns of the commenter since most multifuel boilers combust combinations of biomass and coal. Further, in the final rule EPA has defined the subcategories based on the annual heat input contribution from each fuel type.

Comment: MPU recommends that EPA modify the process for establishing maximum input limits during performance testing. For example, the proposed rule would require the measurement of the chlorine content in the input fuel and use that value to establish a maximum chlorine input limit. The proposed rule does not consider the ability a process may have to inherently control emissions. It would certainly be possible to calculate a removal efficiency that could be used to calculate how high the chlorine content of the input fuel could be before an exceedance of an emission limit would occur.

The rule also proposes to establish site specific minimum sorbent injection rates based on pollutant performance tests. This requirement ignores the fact that sorbent injection rates are affected and controlled by other pollutants and boiler operating conditions. For example, in a CFB boiler the fuel sulfur content, bed temperature, and bed depth will have a major impact on the required sorbent injection rate.

Response: EPA has retained the fuel measurement provisions in the final rule. In many instances EPA expects the control device to be operating at its maximum efficiency during the inital performance test in order to achieve the emission limits under the worst case fuel and load conditions. We recognize that some units and fuel type combination may be able to install controls that operate at a fraction of their maximum removal efficiencies in order to meet the limit. See response to comment excerpt EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for response to cases where inherently low chlorine or mercury fuel inputs may have exceptions to the fuel testing requirements.

Comment: Secondary Materials as Fuel Sources.
The existing biomass power industry consists of industrial boilers that fire from wood waste or wood liquors. According to the USFS about 1 -2% of mill wood waste goes unused. [Smith, W.B., et al. 2007. Forest Resources of the United States, 2007. United States Forest Service, Gen.Tech Report WO-78. December, 2008] Therefore, the biomass power industry is looking to new materials to provide fuel. According to various projections of biomass supply, construction and demolition debris (C&D) is likely to play a major role in meeting this need. Some federal and state legislation already permit the use of C&D as a renewable fuel. Even after sorting, this fuel stream inevitably contains wood treated with copper-chromium-arsenate (CCA), and can contain other wood preservatives, including PCB's. Unfortunately, it appears from EPA's recent draft waste rule that the agency does not appreciate the potential for contamination of these secondary materials. Visual sorting of secondary fuel materials in C&D waste and disaster debris is expensive and time-consuming. Wood treated with CCA can sometimes be identified by its

green tint, however after a number of years this green stain fades. Identifying C&D that is painted with lead paint is also difficult unless a restrictions is set restricting all painted wood, but the industry has consistently resisted such restrictions. EPA appears to not appreciate how difficult it is to control the contamination levels in such fuel streams. The Agency states,

For units that choose to comply with either the mercury emission limit or the HCl emission limit based on fuel analysis rather than on performance stack testing, we are proposing that you maintain daily fuel records that demonstrate that you

burned no new fuels or fuels from a new supplier such that the mercury content or the chlorine content of the inlet fuel was maintained at or below your maximum fuel mercury content operating limit or your chlorine content operating limit set during the performance stack tests.

However, C&D materials and disaster debris by their definition are materials whose characteristics are determined by the demolition of structures with varying age and compositions and thus are constantly changing. How does the EPA propose to define whether the fuel type constitutes a change or mixture that would require recalculations and perhaps new performance tests? Monitoring emissions based on daily record as an alternative to stack emissions is unrealistic at best.

Response: Unless C&D materials have received a non-waste determination, and therefore do not contain any significant level of contaminants, these materials are not considered fuels and are not expected to be combusted in affected sources under this rulemaking. EPA has retained its definition of fuel type in the final rule. Biomass encompass a broad range of materials which as the commenter points out are not all homogeneous. The term biomass encompasses cellulosic biomass such as forest-derived biomass, sawdust, wood chips, bark, bagasse, biomass crops used specifically for energy production, clean wood found in disaster debris, and resinated wood products. Whereas a switch in the source of wood chips would not constitute a new fuel, a switch from wood chips to a nonwood biomass, such as bagasse should be considered a switch in fuel given the differing physical and chemical characteristics of wood as compared to the nonwood biomasses. Note that the definition of fuel type does not classify individual fuel types received from different suppliers as new fuels.

Comment: We understand from the proposed rule that we must establish a maximum mercury and chlorine content of the fuel during the performance stack test, and maintain levels of chlorine and mercury at or below those levels to assure continuous compliance. If a fuel with a higher mercury or chlorine content were to be considered we assume there is a provision for running this fuel and conducting stack testing to confirm continued compliance. If such a stack test indicates emissions in excess of the emission limit, then the previous mercury or chlorine content that demonstrated compliance with the emission limit applies. EPA must appreciate that there may be several “trial and error” type runs with emission testing to establish the maximum acceptable chlorine and mercury content, and some of this testing may need to take place after the compliance deadline if other fuel types were to become available in the future.

Response: The general Part 60 rules provide flexibility for testing new fuels (60.8). The facility would need to seek approval for these tests after initial performance testing. Use of fuel content data and heat and associated emissions factors should be sufficient to inform the facility as to whether it needs to seek EPA approval for such tests.

Comment: Affected sources using fuel specifications to comply with Hg and chlorine HCl emission limits must be allowed to establish fuel quality limits based on extrapolated test results. Conditions achieved during a one-time emissions test are not representative of conditions that occur over an extended period of time. The available compliance methods in the proposed regulation do not enable the affected source to accurately identify the range of representative operating conditions that will meet the Hg and HCl emission limits.

Options that have typically been used by other source categories to simulate worst-case operating conditions (such as spiking of fuels and on-site sample analysis) are not feasible and are economically burdensome for coal fired boilers. Analytical methods for stack emissions (Hg and HCl) and fuel composition (Hg and Cl) that produce real time results are costly and not common practice based on available analytical test programs. Other source categories simulate worst case conditions for multiple pollutants by spiking process streams. Spiking coal with Hg and Cl to simulate worst-case conditions is impractical. One reason is that spiking a solid fuel does not ensure a homogenous fuel source. Secondly, Hg emissions depend on the type and composition of coal, not solely on the amount of Hg within coal. Spiked mercury would upset the balance and composition of coal being burned. This significantly altered composition would not represent actual operating conditions. For these reasons, the current compliance provisions do not allow operators of coal boilers to simulate worst case conditions during the compliance demonstration.

Typical performance tests involve off-site analysis of samples collected during stack testing. Thus, the compliance determination is made days after the performance test when analytical results are made available. Operators therefore conduct these “blind” tests under best-case conditions to ensure that the standards are met. These best-case conditions are likely to produce test results that are a fraction of the emissions standards. It is impracticable for operators of these sources to operate continuously within the Hg and Cl composition parameters established during these onetime performance tests due to fuel availability and composition variability as described in Celanese Comment 3.

For these reasons, the proposed rule must allow affected sources to extrapolate operating parameters from the test results to demonstrate compliance with emission limits. Parametric limits established by extrapolation better represent the range of conditions under which the source would operate. For example, consider an affected source that controls HCl and Hg emissions by limiting the Cl and Hg content of coal. While demonstrating compliance with the Hg emissions standard, the source also demonstrates an HCl emission rate that is a fraction of the emission standard. The source determines that HCl and Hg emissions are linearly related to Cl and Hg content of coal. Based on this analysis, the operator of the source must be able to extrapolate fuel content of Cl and Hg to demonstrate compliance with established emission limits for HCl and Hg. If this extrapolation process is prohibited, operators of these sources would be required to perform multiple stack tests that are unnecessary. In addition, establishment of parametric limitations based solely on fuel composition achieved during the performance test is unduly burdensome and in some cases will prohibit sources from operating when fuel variability limits operation. Therefore, to prevent this certain occurrence, EPA must allow the affected source to extrapolate the fuel composition parametric limit based on test conditions.

Response: The maximum input levels for chlorine and mercury determined from equations 7 & 8, respectively, are not operating limits but are rather levels which can be used to provide an indication of whether a fuel switch may affect the source's compliance status.

Comment: While this compliance scheme may be appropriate for some sources with very stable fuel supply and usage, it may be very cumbersome and burdensome for other sources. It involves a great deal of recordkeeping and potentially subjects the source to frequent testing requirements. As an example of the complexity this proposed compliance plan involves, Section 63.7550 (c)(4) requires that among other things, the semi annual report is to have the supplier of the fuel and original source of the fuel. To make the proposed compliance plan work (which we do not believe can be done), the Agency would have to be much more explicit for instance in its definition of the original source of the fuel. Furthermore, that definition would need to consider as many contexts as exist in the market for fuel generation, distribution, and delivery; e.g., if the fuel is from a distributor or supplier or if the fuel is from a specific mine/property or wash plant. It appears that the objective for the operating limits that are based on fuel analysis is to ensure that the pollutant (chlorine, metals, mercury) input to the source for a given level of operation does not exceed the input level demonstrated during the performance test, where compliance with emissions limitations and work practice standards was demonstrated.

Response: The amount of detail that is necessary in documenting the original source of the fuel is necessarily a case-specific decision, related to how much information is necessary to determine if the fuel constitutes a new fuel, consistent with the definition for "fuel type." Note that the rule does not specifically require documentation of the original source of the fuel in all instances, but rather requires a description of the fuel in 63.7550(c)(4), and the type(s) of fuel used in 63.7555(d)(1).

Comment: The performance testing requirements for a multi-fuel boiler are unclear. For example, GPI — Macon Mill operates an existing unit that would be classified as a "designed to burn biomass" unit because on an annual basis, the heat input capacity of coal is less than 10%. However, on a short-term basis, the unit is capable of combusting 100% coal.[8 In reviewing hourly fuel usage data on this unit, in the past two years, GPI has operated the unit at greater than 10% coal (heat input basis) for approximately 8% of the total hours of operation, with isolated hourly spikes around 90% of the heat input at that time.] As the coal potentially has the highest levels of HC1 and Hg, would GPI — Macon Mill be required to test this unit at 100% coal and compare those emissions to the limitations for boilers designed to burn biomass as that would be the classification? Or is the intent for such units to test using a fuel mix that is representative of typical operations? GPI — Macon Mill is also concerned about the possibility of establishing different operating limits for different fuel scenarios as the practical implementation could be challenging. GPI — Macon Mill requests that EPA give more consideration to the challenges of conducting performance tests on multi-fuel boilers and provide more specific input as to the expectations for such performance testing.

Response: The Agency practice has been to burn the worst mix of fuel expected to be used, based on past performance. If there is no reasonable expectation that the facility would use more than 10% coal, and never has, then that level of coal would be appropriate.

Comment: EPA Should Provide Flexibility In Determining Appropriate Fuel Input Operating Limits. The general compliance plan outlined in the proposed rule is that sources; demonstrate compliance with applicable emissions limitations and work practice standards through the conduct of an initial performance test; establish operating limits based upon results of the performance test; conduct monitoring and maintain records demonstrating that the source is operated on a continuous basis consistent with the operating limits established during the performance test; and periodically repeat the performance testing.

Operating parameter limits based on fuel input analysis (e.g., HCI and Hg), are established using Equations 7 and 8 in section 63.7530. Then, on a continuing basis, facilities are required to keep extensive records of all fuels burned (i.e., fuel type, fuel supplier, fuel mixture, and fuel usage amount) in each boiler or process heater during each compliance reporting period. If a source changes fuels (type, supplier, etc.), it must re-calculate its fuel input values using applicable Equation 7 or 8. If the re-calculated value exceeds the existing limit, the source is required to conduct a new performance test and establish new operating limits.

While this compliance scheme may be easy to manage for some sources, especially ones with very stable fuel supply and usage, it may be very cumbersome and burdensome for other sources with variable fuel suppliers and fuel mixes. This approach involves a great deal of recordkeeping and potentially subjects the source to frequent testing requirements if fuel content varies, regardless of the margin of compliance shown during the initial performance test. Under the proposed rule, even if a unit is operating at 50% of the applicable emission limit, the facility would be required to re-test if the fuel chloride input increases 1% over the level achieved during the initial performance test.

A more appropriate approach is to allow the source to set operating parameters at levels that generate emissions at the emission limits established in the rule. This is the only approach which meets the requirements of the CAA, since it is the only approach that does not impose a beyond the floor limit which has not been justified per the requirements of section 112(d). Under this approach, the source would simply do the performance test using its normal fuel mix, determine operating conditions that show compliance and then adjust those conditions, using engineering calculations to assure it would meet the emissions standards established in Table 1 or 2. If the initial performance test shows emissions at 50% of the standard at a particular mercury or chloride fuel input, the fuel input limits should be set at a level higher than the performance test values, taking into account control device operating parameters as appropriate. This approach would be environmentally beneficial and would greatly reduce burdens.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for flexibility in exceeding the maximum fuel input.

Comment Excerpt Number: 182

Comment: Compliance could also be demonstrated through the use of fuel purchase specifications. Sources would determine from the performance test a maximum fuel pollutant concentration at which the emissions limitations are achieved. For instance, the performance test may demonstrate that fuels containing chlorine in concentrations less than x lb Cl /MMBtu allow the source to comply with emissions limitations. A facility should be allowed to extrapolate an allowable fuel input based on a comparison of performance test conditions to the applicable emission limit. The source would then set a fuel specification of x lb Cl/MMBtu and would be allowed to burn any fuel of the same general type (e.g., solid, liquid, or gas) as long as it met this specification. Sources could require that the fuel supplier provide periodic certification that the fuel meets the specification, based on analysis, or could establish an internal sampling and analysis program for that purpose. In any case, where common fuels are utilized in more than one unit, common fuel quality data would be maintained and considered applicable to all such units. Continuous compliance could also be demonstrated through ongoing fuel analysis.

As an example, sources would (1) establish a fuel input limit (e.g., lb Cl/MMBtu) based on the compliance test as described in the proposal (with an allowance for extrapolation); (2) periodically sample and analyze each fuel for constituent concentration and heating value according to a specified sampling and analysis plan; (3) monitor the daily usage of each fuel; (4) calculate the average total daily constituent input (lb/MMBTU) accounting for all fuels fed; and (5) demonstrate that the average daily constituent input rate averaged over each month of operation does not exceed the operating limit. This option would afford the source the opportunity to vary fuel mixes, while still insuring that protective operating limits are met.

Given the wide variety of sources impacted by this proposal, it is reasonable to provide flexibility in how sources demonstrate compliance, as long as clearly-defined compliance objectives are met. ACC requests that EPA include the compliance schemes discussed above in the final rule as allowable optional compliance strategies. We are willing to work with the agency to further refine these strategies. Additionally, ACC requests that the final rule include an allowance for a source to use, with prior Agency approval, other compliance strategies that may be more appropriate on a site-specific basis.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for flexibility in exceeding the maximum fuel input and the use of fuel purchase specifications.

Comment: There exists an inherent variability in coal quality of the nation's coal supply. The proposed rule requires performance testing and fuel analysis for the worst case fuels with the highest chlorine, mercury, and/or total selected metals content in order to establish operating parameter limits. Due to the fuel variability, it is impossible to identify a worst case fuel, and would require a great deal of recordkeeping and additional performance testing. In addition, the truck and belt fuel sampling and daily fuel usage records as outlined in the proposed rule are not workable to some units as the coal bins are connected directly to the boilers. This approach also results in a fuel sample which is not representative of the fuel that is actually being combusted in the boiler during the performance testing due to the storage capacity between the truck and the boiler.

Response: See response to EPA-HQ-OAR-2002-0058-2845.1, excerpt 34 for recognition that worst-case for one parameter may not be worst-case for another parameter. EPA-HQ-OAR-2002-0058-2763.1 excerpt 28 for response to maximum mercury and chlorine inputs.

Comment: Performance testing is required to be conducted under "representative operating conditions." See 40 C.F.R. section 60.55c(b)(1). The rules do not define the term "representative operating conditions." However, EPA's National Stack Testing Guidance suggests that such conditions: (1) represent the range of conditions under which the facility expects to operate (regardless of the frequency of the conditions); and (2) are likely to most challenge the emissions control measures of the facility (but without creating an unsafe condition). Clean Air Act National Stack Testing Guidance at 14. This guidance further defines "representative" as "normal" as it states that "The MACT program further defines representative performance as normal operating conditions" and again when describing the performances test conditions as described above to be "under...those representative (normal) conditions...." Id. Of course, as expressly stated in the document itself, the National Stack Testing Guidance is "intended solely as guidance" and, as such, "is not a regulation." Id. at 2.

Properly conducted, performance tests are, indeed, a reliable measure of compliance at a given point in time with the relevant standard. However, such tests typically should not be expected to reveal the true range of variability in operating conditions because sources strive to maintain rigorous, yet consistent, operating conditions during tests, between testing runs within a given testing session, and between testing sessions. As indicated by the Stack Testing Guidance, the goal of performance testing is to challenge the applicable control device or control measure to assure that compliance will be maintained under rigorous conditions. Variable operations during testing are inconsistent with the purpose and intent of such testing.

Moreover, while owners and operators may seek to conduct testing at reasonable worst case conditions to assure compliance during less rigorous conditions, it is entirely possible that operations during less rigorous conditions could nevertheless accommodate variation that would not threaten compliance with the standard, but nevertheless could be relevant when the data are used to set standards on a pollutant-specific basis rather than a unit-specific basis. As a hypothetical example, the most rigorous testing condition for HCl emissions from a given boiler might be a feed with high halide content. Thus, it would be logical for testing to be performed under these conditions. However, other HAP constituents in the feed – such as metals – would not necessarily be at "worst case" levels during testing focused on halides. In this scenario, the testing might show extremely low levels of metals emissions, which would not necessarily reflect higher levels of such emissions that might occur during normal operations.

Response: See response to EPA-HQ-OAR-2002-0058-2702.1, excerpt 19 for explanation of representative operating conditions. See response to EPA-HQ-OAR-2002-0058-2845.1, excerpt 34 for recognition that worst-case for one parameter may not be worst-case for another parameter. See response to comment excerpt EPA-HQ-OAR-2002-0058-3213.1, excerpt 126 for discussion of a plan to incorporate a site-specific fuel analysis monitoring plan.

Comment: While owners and operators may seek to conduct testing at reasonable worst case conditions to assure compliance during less rigorous conditions, it is entirely possible that operations during less rigorous conditions could nevertheless accommodate variation that would not threaten compliance with the standard, but nevertheless could be relevant when the data are used to set standards on a pollutant-specific basis rather than a unit-specific basis. As a hypothetical example, the most rigorous testing condition for HCl emissions from a given boiler might be a feed with high halide content. Thus, it would be logical for testing to be performed under these conditions. However, other HAP constituents in the feed – such as metals – would not necessarily be at “worst case” levels during testing focused on halides. In this scenario, the testing might show extremely low levels of metals emissions, which would not necessarily reflect the higher levels of such emissions that might occur during normal operations.

Response: Sources must test under conditions that are representative of the source’s ability to comply continuously with the emission standards. If the source believes that conditions at maximum normal operating load are not reflective of conditions that most challenge the source's ability to comply, they may specify what other conditions are more reflective of continuous compliance in their test plan, required under the General Provisions at 63.7(c). Further, the regulations have been amended to clarify that you must conduct performance stack tests at the maximum normal operating load while burning the type of fuel or mixture of fuels that has the highest content of particulate matter, as well as of mercury and chlorine. EPA recognizes that this may result in the need to conduct more than one performance test, as reflected in the language at § 63.7520(c) which states, "These requirements could result in the need to conduct more than one performance test."

Emissions Averaging

Comment: EPA's proposed restrictions on emissions averaging are not consistent with the scale of industrial, commercial and institutional boilers.

EPA appears to have relied heavily on the rationale for emissions averaging as part of a MACT standard presented in its 1994 Hazardous Organics NESHAPS ("HON") found at 59 Fed. Register I 9425 (April 22, 1994).[Paragraph 5 of Sectioj V.D, "Emissions Averaging," of that 1994 FR notice includes a sentence that states, "However, the HON emissions averaging system…should not be viewed as setting a precedent for future MACT standards."] One of the provisions that EPA included in the current proposal is that there would be "no averaging between individual sources that are not part of the same affected source." Such a restriction may be reasonable when the "affected source" is a large refinery or electric generating power plant with a number of individual sources on one distinct and expansive parcel. However, industrial boilers, particularly those associated with district steam systems, are often smaller sources that are spread throughout a distinct system or process, but located on separate property parcels. In actuality, the emission sources in such a system could be in closer proximity to each other than sources within the geographic boundary of a large refinery operation.

A particular example would be a college campus that includes several boilers, but whose buildings are spread over a number of property parcels within a small geographic area, such as a small city. Typically, all of the boilers provide steam to the same underground system and are under common control and management. In such an instance, a significant investment in fuel-switching or control equipment in one boiler could be used to offset the emissions from the remaining boilers on the system, resulting in an overall reduction that, averaged, allows all of the boilers to meet the MACT standard. Allowing these interconnected boilers to employ emissions averaging would maximize the incentive for one or more of the boilers to switch to the lowest-possible emitting fuel or to install the most effective control technology. Accordingly, to promote this efficiency without sacrificing the desired air quality management objectives, the Company suggests the following additional text (shown in ALL CAPS) to proposed § 63.7522(a), found in the Federal Register notice at page 32053:

"(a) As an alternative to meeting the requirements of § 63.7500 for particulate matter, HCI, or mercury on a boiler or process heater-specific basis, if you have more than one existing boiler or process heater in any subcategory located at your facility OR IF NOT ALL ARE LOCATED ON A COMMON PARCEL, BUT ARE CONNECTED TO A COMMON PIPING OR PROCESS SYSTEM AND ARE UNDER COMMON OWNERSHIP AND CONTROL you may demonstrate compliance by emission averaging, if your averaged emissions are within 90 percent of the applicable emission limit,. according to the procedures in this section."

To make the provisions consistent, the text of § 63. 7522(g)(4)(i) (Federal Register notice page 32054) should be modified as follows:

"(4) The applicable regulatory authority shall not approve an emission averaging implementation plan
containing any of the following provisions:

(i) Any averaging between emissions of differing pollutants or between differing sources (EXCEPT AS PROVIDED FOR IN § 63.7522(a));"

Response: EPA thanks the commenter for their input but notes that 'facility' is the preferred term in this instance. EPA must ensure that compliance provisions such as emissions averaging have appropriate limitations to ensure equal protection of human health and the environment. Further, 'facility' was the term used in the emissions averaging provisions of the vacated rule.

Comment: Thirty percent of these costs, however, will be related to non environmental improvements such as redesigning stacks to account for the provisions of emissions averaging which do not allow us to average over subcategories when –- for boilers that burn similar fuels .

An example of this is one of our facilities burns -– has three boilers connected to a common stack. Two of them burn coal with tangentially fired units; the other one is stoker fired. They had different limits. Under the current rule we would not be able to emissions average these boilers; therefore, a significant amount of investment required to just separate the stacks in order to meet the rule. Again, these investments under the current rule would not benefit the environment at all.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcategories.

Comment: Dioxins/furans should be included.

A source should be allowed to comply with the dioxin/furan (D/F) standard via emission averaging. While Eastman does not believe it is appropriate to set numerical emission standards for D/F (see comments elsewhere), if the final rule does include such numerical standards, a source with multiple units could choose to comply by installing a post-combustion control (such as powder activated carbon injection) to reduce D/Fs (note, this example does not imply Eastman believes such technology has been demonstrated on industrial boilers) on some units at a facility. By the same rationale that would justify allowing use of emission averaging for other HAPs, sources should be allowed the flexibility to over-control at some units at a facility and under-control at others in order to reduce the overall compliance costs for the facility.

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.

Comment: Carbon monoxide should be included.

Some units may be able to easily meet the proposed CO limits, while, for others, it may impossible. Therefore, CO should be included in the emissions averaging provisions. To facilitate its inclusion, the emission limitation for CO should be expressed in an alternative form – lb/mmBtu. For the case of units using CEMS to measure CO, we reference an existing emission averaging provision for NOx found at 40 CFR 76.11. Heat input should be allowed to be determined using either flow monitors (some units subject to the NOx budget trading program have these already) or using fuel factors and diluent monitors per 40 CFR 60 Method 19.

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging and response to EPA-HQ-OAR-2002-0058-2702.1, excerpt 206 for alternative units of measure for CO.

Comment: Averaging across subcategories should be allowed. The proposed emission averaging provision appears to only allow averaging within a subcategory (see §63.7522(a).

On page 32034 of the preamble, EPA states one of its limits on the scope of emissions averaging is to not allow averaging between sources that are not part of the same affected source. In this case, EPA has elected to define the affected source in §63.7490(a)(1) as all units within a subcategory. We see no reason for EPA to use this definition. Rather all units at a given facility subject to the subpart should be collectively considered the “affected source”. This is how EPA has defined the term in other rules with which we are familiar (e.g. the HON in Subpart F, Polymer and Resins 4 in Subpart JJJ, the MON in Subpart FFFF). The HON in particular we understand is the model EPA is using to guide its policy. By defining the term affected source as all chemical manufacturing process units (CMPUs) at a facility, the HON allows emissions averaging across CMPUs and across emission unit types (vents, storage vessels, transfer racks, wastewater stream). There is no reason in the boiler and process heater MACT for EPA to restrict the emissions averaging alternative as it has proposed. To do so, will prevent some facilities from taking advantage of the opportunity to avoid otherwise cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination.

Also, by not allowing averaging across the different fuel categories, EPA removes an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from a coal-fired unit.

It is not clear from the proposed rule language if EPA intended to restrict averaging across subcategories. While the wording under the separate stack requirements does seem to have this restriction, the wording under the common stack requirements does not (see Equation 6). In any event, as stated above, there should be no such restriction.

As in the HON, the compliance methodology can easily accommodate subcategories with different emission limits for a given pollutant. This is done basically by calculating a weighted average allowable mass emission and a weighted average actual mass emission each month using heat inputs or steam production for each unit.

At one of its facilities, Eastman operates boilers in two subcategories (stokers and pulverized coal) for which we are likely to take advantage of the emission averaging provision. These boilers are in separate powerhouses. We urge EPA to remove the restriction (or clarify its intent) that such averaging is allowed, regardless of whether the boilers emit through separate or common stacks.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcatgories.

Commenter Name: Trina L. Vielhauer
Commenter Affiliation: Florida Department of Environmental Protection, Division of Air Resource Management
Document Control Number: EPA-HQ-OAR-2002-0058-2527.1
Comment Excerpt Number: 4

Comment: The Division does not support the emissions averaging concept outlined in the proposal. While such an approach may work satisfactorily for similar emissions units with similar and contemporaneous control equipment, it would not necessarily be appropriate in all cases. In addition, the Division does not believe that emissions averaging among similar units at a facility is within the spirit and intent of the MACT program.

Response: EPA acknowledges the concerns of the commenter. However, it has retained the emission averaging provision in the final rule. The emission averaging concept was also an element of the vacated 2004 rule, and although the format in this final rule is slightly modified from the vacated rule, the same spirit is retained. Further, this revised emission averaging provision includes additional mechanisms that are protective of the public health, such as incorporating a discount factor to determine eligibility for emissions averaging. Further, the final rule includes a provision to have the emissions averaging implementation plans reviewed an approved, upon request in order to allow regulatory authorities to provide input on specific plans.

The final rule is not the first NESHAP to include provisions permitting emission averaging. The legal basis and rationale for emissions averaging were provided in the preamble to the final Hazardous Organic NESHAP (59 FR 19425, April 22, 1994). In general, EPA has concluded that it is permissible to establish within a NESHAP a unified compliance regimen that permits averaging across affected units subject to the standard under certain conditions. Averaging across affected units in the same subcategory is permitted only if it can be demonstrated that the total quantity of any particular HAP that may be emitted by that portion of a contiguous major source that is subject to the NESHAP will not be greater under the averaging mechanism than it would be if each individual affected unit complied separately with the applicable standard. Under this rigorous test, the practical outcome of averaging is equivalent in every respect to compliance by the discrete units, and the statutory policy embodied in the MACT floor provisions is, therefore, fully effectuated.

Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 5

Comment: Compliance should be based solely on actual emissions.

The proposed provisions require (1) a demonstration that the average weighted emissions is less than 90 percent of the applicable emissions limit assuming each unit is operating at its maximum rated heat input capacity (see Equation 1) and (2) a demonstration each calendar month that the average weighted emissions is less than the applicable emissions limit using the actual heat inputs for that month.

There is no rationale for the first test and it should be eliminated. Other rules that allow emission averaging (again, see the HON), include no such requirement. Such a requirement could be unduly restrictive. For example, a facility may have one older unit and a newer unit which they would like to average. The older unit may have a much lower capacity factor (ratio of actual usage divided by rated capacity) than the newer one. Older units typically have much more space constraints and a facility may be facing steep compliance costs to bring the older unit into compliance and may have an opportunity to over-control the newer unit. Given that the newer unit has a longer remaining life expectancy, such a facility should be incented to over control the newer unit. Yet, Equation 1 may block the facility from taking advantage of the emission averaging flexibility, especially if the older unit has a comparable or even higher rated capacity than the newer unit.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor. The maximum rated heat input capacity was also used in the vacated rule in order to ensure adequate protection of the environment. Most of the commenters requesting for use of the actual instead of maximum rated heat input capacity were concerned with limited use units which have now been addressed using a separate subcategory. EPA does not agree that the intent of the MACT program is to allow infrequently used, but older coal units to participate in emissions averaging unless they can demonstrate that under maximum operating conditions the unit can meet the emission limit under the emissions averaging provision.

Comment: Compliance on a monthly basis during the first twelve months of compliance period is unworkable.

Proposed §63.7522(f)(3) requires a facility to generate enough credits to offset the debits each and every calendar month up until 12 months are accumulated and, thereafter, determine compliance on a twelve month rolling average basis. This requirement unnecessarily restricts the utility of the emission averaging provision. For example, in the case where a facility over-controls one boiler while under-controlling the other, there will be months when the facility could not comply. This would certainly be true during a month when the credit-generating unit is down for its periodic maintenance outage. Due to the necessary length of these outages (4-6 weeks), there could conceivably be two or three months in a row where the facility could not comply with proposed averaging provisions. There will be other cases where the credit-generating unit experiences an unanticipated outage and the debit-generating unit is required to operate more to compensate. For these reasons, this provision should be eliminated. Eastman notes that the HON, which EPA references, includes an annual emission test along with a quarterly emission test where the average emissions must be less than 130 percent of the allowable emissions. Here, EPA acknowledges that a short term average (quarterly) must provide some tolerance as compared to an annual average. We bring this point up, not to suggest to EPA to adopt the HON quarterly test, but to illustrate that EPA emissions averaging provisions have accounted for this issue. Also, we would note that the HON is written for an entirely different industry than the case of boilers and process heaters. Due to the circumstances described above (extended outages while other units take on additional load), a facility using emissions averaging for boilers and process heaters should be subject to only annual compliance determinations.

Response: See response to EPA-HQ-OAR-2002-0058-2824.1, excerpt 23 for response to comment on timing of first compliance demonstration.

Comment: The 10 percent penalty for using emissions averaging is arbitrary, unnecessary, and should be removed.

First, it appears the 10 percent discount factor discussed on page 32035 of the proposed rule should be in the denominator in Equations 1 – 4. EPA solicits comment on this discount factor and states that its inclusion further ensures the allowable emissions are at least as stringent as the MACT floor limits without using averaging. Given the accuracy of heat input weighted emission calculations, Eastman does not see that there is any uncertainty that the average emission rates will be any less stringent than when not using averaging. This discount factor is arbitrary and should be eliminated. Its inclusion reduces the flexibility the averaging concept provides.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: Myra C. Reece

Document Control Number: EPA-HQ-OAR-2002-0058-2525.1
Comment Excerpt Number: 7

Comment: The EPA proposes that "for each existing boiler or process heater in the averaging group, the emission rate achieved during the initial compliance test for the HAP being averaged must not exceed the emission level that was being achieved on the date 30 days after publication of the final rule in the federal register or the control technology employed during the initial compliance test must not be less effective for the HAP being averaged than the control technology employed on the date 30 days after publication of the final rule in the federal register (75FR 32053)." The EPA reasons that these "caps would ensure that emissions do not increase above the emission levels that sources currently are designed, operated, and maintained to achieve" (75FR 32034).

In order to enforce and implement the cap requirement, the EPA proposes to require facilities choosing to demonstrate compliance by the emission averaging option to submit an "implementation plan" for review and approval by the delegated authority. Additionally, in section IV.L of the preamble of the proposed rule, the EPA recognizes that it "must ensure that any emissions averaging option can be implemented and enforced" and "will be clear to sources" (75FR 32034); however, the EPA did not provide a clear process for implementing and enforcing this complex compliance option.

Emission Caps For Existing Affected Sources Choosing To Demonstrate Compliance By The Emission Averaging Option Cannot Be Effectively Implemented Or Enforced. The Emission Cap Should Be Included In The Compliance Calculations

We believe that the requirement to establish an emission cap and submit an implementation plan to the permitting agencies for approval is problematic as written. Because the emission cap is not used in the initial compliance demonstration or in demonstrating continuous compliance with the emission averaging option, it is of little use.

If the intent of this option is for facilities to not exceed the cap at any time, then a demonstration methodology showing that the cap is not being exceeded needs to be included in the compliance equations in 63.7522. If the cap is included in the compliance equations, facilities could certify compliance with the cap in the notice of compliance status (NOCS) and within each required semiannual report. Additionally, if the initial and continuous compliance measures include the emission cap, the implementation plan will not be necessary and states will not have to spend valuable time and resources to approve these plans.

We received several implementation plans from facilities trying to comply with the vacated Boiler MACT rule in 2007. We encountered many problems with the approval process and received little help and guidance from the EPA. The EPA used the same approval process in the new proposed Boiler MACT rule disregarding the known problems states faced trying to implement the vacated rule in 2007.

Response: See response to EPA-HQ-OAR-2002-0058-3213.1, excerpt 180 for response to comment on timing of first compliance demonstration.
We have included an item in the notification of compliance status to report the control devices employed or emissions levels being achieved 60 days after publication in the federal register. We have also included a new certification item in the ongoing compliance reports to certify that the the current control device configuration or emissions levels being achieved are no less stringent than the control devices employed or emissions levels being achieved 60 days after publication in the federal register. These items will help aid delegated authorities in determining compliance with the emissions averaging provisions. However, EPA also determined that given the complexity of the emissions averaging, the emissions averaging implementation plan is still a required report that should be submitted and approved by the relevant delegated authority. The final rule includes criteria to help guide delegated authorities in the criteria used to review and approve each reports.

Comment Excerpt Number: 8

Comment: The Clean Energy Group supports EPA's efforts to allow emissions averaging for ICI boilers,
recognizing the smaller nature of the source category and the need for regulatory flexibility. As EPA noted in the preamble, emissions averaging provides sources the flexibility to comply in the least costly manner while maintaining workable and enforceable regulation. Because emissions averaging represents an equivalent, more flexible, and less costly alternative for many units, we agree with EPA that the averaging proposed in this rule would likely result in cost and energy savings to owners and operators. Additionally, we agree that the proposal meets the Clean Air Act's requirements and EPA's previous policies regarding the scope and nature of emissions averaging programs.

Response: EPA acknowledges support of the emission averaging provision and has retained the emission averaging provision in the final rule.

Commenter Name: Michael Bradley
Commenter Affiliation: The Clean Energy Group
Document Control Number: EPA-HQ-OAR-2002-0058-2466.1
Comment Excerpt Number: 9

Comment: We disagree with EPA's use of a discount factor. This appears to be in contrast to the majority of previous EPA rulemakings that have demonstrated the cost-efficiency and environmental efficacy of averaging provisions, such as those proposed here for the same pollutants at the same facility. The standard monitoring provisions included in this rule are sufficient to ensure compliance with the standards. In addition, there does not seem to be a legal basis for this provision, as it would be arbitrarily increasing emissions reduction requirements beyond both the MACT floor and the identified "beyond-the-floor" reductions. The discount factor would create substantial administrative burdens without any clear environmental, legal, or policy benefits.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 33

Comment: Emission averaging within a source can be an effective means of reducing compliance costs to the source without adversely impacting public health. NACAA generally supports the concept of emission averaging as set out in the proposal provided: (1) there is clear authority to do so under section 112 and (2) the benefits of averaging are fairly apportioned between the regulated community and the public. While emission averaging is helpful to sources on the margin, it should not be adopted if it will cause significant risk that the final rule will be overturned. Where a source is able to achieve more cost-effective emission reductions at one unit, emission averaging offers a "win-win" opportunity that should be embraced without penalty to the source. However, at times, compliance costs are reduced, at least in part, because sources are able to emit more of the regulated pollutant than without emission averaging because they can operate with smaller compliance margins. EPA has solicited comment on whether a 10-percent reduction in the overall emission limit would be appropriate if averaging were allowed, but has offered no estimate on how much of an emissions increase would result from averaging. If the units at issue indeed have the 300-percent to 1000-percent variability that EPA's MACT floor analysis suggests, a 10-percent penalty would seem to allow a fairly significant increase in overall emissions at the source. The increase in emissions could be evaluated by calculating how much the variability is decreased[Presumably, this calculation would be a variation of EPA's determination of the Upper Probability Limit, given the variability of the units and the number of tests needed to show compliance.] when paired compliance demonstrations are to be made. It may be that this issue can also be addressed by appropriate corrections to the MACT variability analysis and compliance demonstration provisions.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor. Regarding re-analysis of the impact a discount factor would have on the emissions impacts associated with this rule making, EPA does not have the data in hand to quantitatively assess how the incorporation or removal of a discount factor would affect the compliance margins a source operates with. EPA has identified that including a discount factor will provide additional compliance flexibilities to a limited subset of units that are consistently below the emission limits.

Comment: The proposed emission averaging is explained as allowing averaging only within a subcategory [Footnote: See 75 Fed. Reg. at 32,024.] although it is not clear from the proposed rule language if this is what EPA intended. [Footnote: See 75 Fed. Reg. at 32,053 (proposed § 63.7522(a)).] While the wording under the separate stack requirements does seem to have this restriction, the wording under the common stack requirements does not. [Footnote: See 75 Fed. Reg. at 32,055 (Equation 6).] EPA provides no justification for restricting averaging to a given subcategory nor is it rational to impose such a restriction.

Some affected units involve multiple boilers operating in different subcategories (e.g. stokers and pulverized coal). These boilers are generally located in separate powerhouses. The goal of emissions averaging is to allow facilities to over control some emissions points while under controlling others, thus achieving the required reductions in the most cost-effective manner possible. This could be best achieved by EPA removing the restriction (or clarifying its intent) that such averaging would be allowed for all affected units, regardless of whether the boilers emit through separate or "common stacks." The rule should allow for averaging across all units regardless of category of pollutants to be averaged so long as emissions from a single unit can be quantified with testing either in the breeching or in the stack when other units are not operating. Allowing averaging across subcategories within the rule is consistent with the four averaging criteria described in the preamble:

(1) No averaging between different types of pollutants;
(2) No averaging between sources that are not part of the same affected source;
(3) No averaging between individual sources within a single major source if the individual sources are not subject to the same NESHAP; and
(4) No averaging between existing sources and new sources. [Footnote: See 75 Fed. Reg. at 32,035.] Thus, averaging across subcategories is a possible interpretation of the proposal, and EPA should revise this in the final rule.

EPA provides no justification for restricting averaging to a given subcategory nor is it rational to impose such a restriction. Emissions averaging generally allows a facility to avoid otherwise cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination. It also has corresponding environmental benefits, by creating an incentive to burn more natural gas or renewable fuels as a strategy to average out emissions from a coal-fired unit. If the proposed Boiler MACT does not allow averaging across the different fuel categories, EPA removes the incentive for sources to turn to cleaner-burning fuels to achieve averaging benefits.

The legal precursor to introducing emissions averaging is Chevron U.S.A., Inc. v. NRDC. [Footnote: 467 U.S. 837 (1984).] In Chevron, the Supreme Court held that EPA regulations allowing states to treat all of the pollution-emitting devices within the same industrial grouping as though they were encased within a single "bubble" were based on a reasonable construction by EPA. This case opened the door to more specific emissions averaging efforts, such as those implemented in the 1994 Hazardous Organic NESHAP (HON Rule). [Footnote: 59 Fed. Reg. 19,402, 19,425 (Apr. 22, 1994).] Several rules have followed the HON Rule in authorizing emissions averaging, and the D.C. Circuit has never invalidated the approach. The proposed emissions averaging provisions in the proposed Boiler MACT are directly based on the emissions averaging provisions in the HON.
In the HON Rule, EPA thoroughly examined the legal basis for emissions averaging, and explored the degree of averaging permitted under section112(d) of the CAA. At the end of its review, EPA concluded that the statute "does not define source category, nor does it impose precise limits on the Administrator's discretion to define source." [Footnote: 59 Fed. Reg. 19,402, 19,425 (Apr. 22, 1994).] EPA further acknowledged that the CAA does not limit how standards are to be set for a category or subcategory beyond requiring that it be applicable to all sources in a category, be written as a numerical limit wherever feasible, and be at least as stringent as the floor. [Footnote: 59 Fed. Reg. 19,402, 19,425 (Apr. 22, 1994).]

In promulgating the HON emissions averaging requirements, on which the proposed Boiler MACT relies, EPA thus concluded that "the relevant statutory language is broad enough to permit the Administrator to allow sources to meet the MACT through the use of emissions averaging provided the standard applies to every source in the category, averaging does not cross source boundaries, and the standard is no less stringent than the floor." [Footnote: 59 Fed. Reg. 19,402, 19,425 (Apr. 22, 1994).] Allowing emissions averaging across subcategories within the proposed Boiler MACT is consistent with the parameters established in the HON rule, and reiterated in the preamble for the proposed Boiler MACT. [Footnote: See 75 Fed. Reg. at 32,035.] Namely, allowing averaging across subcategories will not result in averaging between (a) different types of pollutants, (b) sources that are not part of the same affected source, (c) individual sources within a single major source if the individual sources are not subject to the same NESHAP, and (d) existing sources and new sources. [Footnote: See 75 Fed. Reg. at 32,035.]

There is precedent in other MACT standards for allowing averaging across different types of units of a single source. For example, the HON rule allows process vents, storage vessels, transfer racks, and wastewater streams to all be included in an emission average across an affected source. [Footnote: See 40 C.F.R. Part 63, Subpart G.] EPA reasoned that averaging needed to be allowed across all emission points (except equipment leaks) in order to provide as much flexibility as possible while maintaining an enforceable emission limitation. [Footnote: 59 Fed. Reg. at 19,425.] Similar mechanisms have been adopted in other MACT standards such as the Petroleum Refinery NESHAP and the Boat Manufacturing NESHAP.[Footnote: See Petroleum Refinery NESHAP, 60 Fed. Reg. 43,244, 43,254 (Aug. 18, 1995) (allowing wide range of emission sources to be averaged, noting that "EPA has the flexibility to allow trading within a facility that includes units in different source categories"); Boat Manufacturing NESHAP, 66 Fed. Reg. 44,218, 44,232 (Aug. 22, 2001).]

As in the HON, the compliance methodology can easily accommodate subcategories with different emission limits for a given pollutant. This is done basically by calculating a weighted average allowable mass emission and a weighted average actual mass emission each month using heat inputs or steam production for each unit.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for response on averaging across different subcategories.

Comment: Averaging across subcategories also should be permitted for dioxins/furans and carbon monoxide. A source should be allowed to comply with the dioxin/furan (D/F) standard via emission averaging. While it may not be appropriate to set numerical emission standards for D/F, if the final rule does include such numerical standards, a source with multiple units could choose to comply by installing a post-combustion control to reduce D/F on some units at a facility.

Additionally, carbon monoxide should be included in the emissions averaging provision, since some units may be able to easily meet the proposed CO limits, while, for others, it may impossible. To facilitate its inclusion, the emission limitation for CO should be expressed in an alternative form – lb/mmBtu. For the case of units using CEMs to measure CO, precedent exists for this as well, in the emission averaging provision for NOx found at 40 C.F.R. § 76.11. Heat input should be allowed to be determined using either flow monitors (some units subject to the NOx budget trading program have these already) or using fuel factors and diluent monitors per 40 C.F.R. Part 60, Method 19.

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.

Comment: EPA also imposes a restriction that requires facilities using that option to meet a standard that is 10% stricter than the otherwise applicable limits. Footnote: See 75 Fed. Reg. at

32,035.] EPA should remove this 10% penalty for using emissions averaging because it is arbitrary, unnecessary for environmental protection and reduces the flexibility that averaging provides. EPA asserts that its inclusion further ensures the allowable emissions are at least as stringent as the MACT floor limits without using averaging. However, EPA offers no demonstration of this in the proposal. Given the accuracy of heat input weighted emission calculations, there is no uncertainty that the average emission rates will be any less stringent than when not using averaging. Because EPA already has determined that the standards in the proposed rule achieve the maximum emission reduction achievable for health and environmental protection, to require an additional 10% reduction of emissions has no basis in the environmental underpinnings of the rule. Given that emissions averaging is a compliance alternative, the 10% discount factor constitutes a beyond-the-floor requirement that EPA has not analyzed for its cost, non-air quality and energy impacts, as required by CAA section 112(d)(2). Finally, although the 10% discount may be perceived as a fair “trade-off” for the flexibility of emissions averaging, it still lacks a legal basis and creates a disincentive for sources to use this compliance method. Because the proposed limits in this rule already are so stringent, sources will not be able to ensure an additional 10% reduction in emissions below the limits and imposing this requirement effectively deprives many sources of the availability of the emissions averaging compliance alternative. For these reasons, EPA should delete the 10% discount in the final rule.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: Proposed § 63.7522 – The requirements in subsection (c) are unclear in that this provision appears to limit the emission rate demonstrated during the initial compliance test to the emission level that was achieved 30 days after the final rule is published in the Federal Register. This contradicts other parts of the proposed rule where a facility is allowed to burn multiple fuels during the initial compliance test to demonstrate compliance with different fuels. One of the fuels demonstrated may be higher in a particular HAP than what occurred 30 days after publishing in the Federal Register and yet be in compliance with the MACT standard.

Response: See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 228 for clarification of the anti-backsliding procedures.

Comment: EPA Should Incorporate Additional Flexibility into the Emissions Averaging Provisions

We agree that incorporating emissions averaging into the Boiler MACT is a proper way to encourage flexibility and cost savings for affected facilities. There is ample precedent in the MACT program for allowing emissions averaging. For example, the Pulp and Paper Chemical Recovery Combustion MACT allows plants to set a PM HAP emissions limit for each existing applicable process unit such that, if these limits are met, the total emissions from all existing process units are less than or equal to a "bubble" limit on all affected units. See 66 Fed. Reg. 3180, 3184 (January 13, 2001) and 40 C.F.R. Part 63, Subpart MM. See also 67 Fed. Reg. 78046 (December 20, 2002) (proposing emissions averaging in the Lime Manufacturing MACT). Many other MACT standards have included emissions averaging provisions, which are conceptually similar. See, e.g., 40 C.F.R. Part 63, Subpart JJJ (Group IV Polymers and Resins); 40 C.F.R. Part 63, Subpart U (Group I Polymers and Resins); 40 C.F.R. Part 63, Subpart G (Synthetic Organic Chemical Manufacturing Industry: Process Vents, Storage Vessels, Transfer Operations and Wastewater); 40 C.F.R. Part 63, Subpart LL (Primary Aluminum Reduction Plants); 40 C.F.R. Part 63, Subpart CC (Petroleum Refineries); 40 C.F.R. Part 63, Subpart EEE (Hazardous Waste Combustors).

Emissions averaging is a well demonstrated technique for meeting or exceeding environmental objectives at lower cost and with greater flexibility tailored to individual affected facilities. Provisions such as these allow plants to optimize their investments by installing controls on units where the lowest emission rates can be achieved in the most cost-effective manner possible. For example, a source could decide to over-control a newer unit in order to avoid costly investments in an older unit that may be retired before the useful life of the control device is reached. Emissions averaging provisions also provide environmental benefit by allowing for control options that minimize energy use. Energy efficient decisions benefit the environment by reducing power demands and the secondary pollutant impacts they generate.

AF&PA concurs with EPA's proposal and past precedent that use of the emissions averaging compliance alternative would be limited to existing units. New and reconstructed boilers/process heaters would be required to meet the more stringent "new source" requirements.

However, we believe that additional flexibility should be incorporated into the proposed emissions averaging provisions in order to ensure facilities have options to reduce the cost of compliance. The emissions averaging provisions should be based on actual operating time and emissions and not capacity. Adding the element of time ensures equivalent control regardless of boiler operating schedules and provides flexibility with respect to the control strategy for limited use boilers. Some boilers are only used during maintenance outages, and incorporating flexibility into the emissions averaging provisions to accommodate limited use boilers will greatly reduce the compliance cost for these boilers. Boilers sharing common stacks should also be eligible for inclusion in the emissions averaging approach, especially if emissions can be measured from each boiler prior to the common stack. EPA has included all common stack units in its MACT floor analyses by applying the measured common emission rate to each unit, instead of one time for the group of units, so this approach could also be used in an emissions averaging compliance scenario.

Response: While EPA did not make major adjustments to the emissions averaging provisions, the change to a solid fuel subcategory will enable all solid fuel-fired units at a facility to use the emissions averaging provision for Hg, PM, and HCl. Beyond this, EPA disagrees that it is appropriate to average across subcategories for affected sources with mixed streams (e.g., SOCMI) and the commenter does not provide sufficient justification for swaying from this precedent.

See response to comment EPA-HQ-OAR-2002-0058-2694.1, excerpt 3, for response to actual vs. rated heat input capacity and a discussion of how units with common stacks can participate in the emisisons averaging provision.

EPA acknowledges the support of past precedent and has retained the prohibitions of the emission averaging provisions for new sources.

Comment Excerpt Number: 176

Comment: In addition, AF&PA believes that boilers of any design firing any fuel (e.g., in any subcategory) should be included in the emissions averaging provisions and that facilities should not be limited to use of emissions averaging only for boilers in the same subcategory. There is no justification for restricting emissions averaging only to boilers in a specific subcategory; facilities should be able to average emissions from stoker boilers with emissions from pulverized coal boilers and liquid boilers. This approach has been used in several of the other rules mentioned above. For example, the Pulp and Paper Chemical Recovery Combustion MACT and the HON allow emissions averaging across different types of units. The equivalency by permit provisions under 40 CFR 63.94 allow sources to “trade” emissions from unregulated sources for emissions of regulated sources, so this is additional reason not to restrict use of emissions averaging to boilers within the same subcategory.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcategories.

Comment: We also disagree that a 10 percent penalty for use of emissions averaging is appropriate. This requirement restricts the utility of the proposed emissions averaging provisions, especially as this demonstration is proposed to be based on unit capacity and not actual unit operating data. The Pulp and Paper Chemical Recovery Combustion MACT allows averaging of emissions with no requirement to further reduce emissions to 90 percent of the allowable emission rate.

We believe that the application of the underlying principles of emissions averaging, as stated in the Proposed Rule, is sufficient to ensure full realization of the statutory requirements of meeting the MACT standards for the affected sources and that no discount factor is required. EPA fails to justify the necessity to further tighten emissions standards when emissions averaging is used. This point is further reinforced by the fact that EPA expressly excluded the provisions of emissions averaging, including the discount factor, to a situation where individual units are vented through a common stack. EPA must realize that there is no difference in actual emissions between two units emitting from separate stacks and the same units, operated in an identical fashion, emitting from a common stack: the quantity of contaminants emitted to the atmosphere will be identical in both circumstances and imposing a discount factor to the units emitting separately will surely discourage any facility from using this compliance option.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment Excerpt Number: 178

Comment: EPA bases its justification for including of a discount factor on the emissions averaging provisions in the Hazardous Organic NESHAP (HON), stating that the legal basis and rational for the HON emissions averaging provisions have been provided in the preamble to the final HON. However, EPA dismisses this discount provision in the preamble to the proposed NESHAP rule for Plywood and Composite Wood Products (PCWP MACT), stating "…(the) HON sources have many emission points, are complex and diverse, and as a result are subject to a more complex set of emissions averaging provisions. The PCWP facilities have fewer emission points within each facility. Therefore, the enforcement concerns arising due to the large number of emission points in each HON facility are minimized for PCWP facilities." EPA concludes its argument to dismissing a discount factor for PCWP sources by stating that "…(the) HON requires a discount factor of 10 percent in credit calculations to share with the environment some portion of the cost savings due to emissions averaging and to account for uncertainty in emissions estimation. Due to differences between PCWP and HON sources (discussed below), we do not believe it is necessary for the proposed PCWP rule to include a discount factor.". This conclusion was maintained in the final version of the PCWP MACT Rule. In fact, the concept of imposing a discount factor on the use of emissions averaging was never discussed neither in the initially proposed nor the previous final Boiler MACT Rule. Hence we believe that imposing a discount factor to the emissions averaging compliance alternative is unwarranted and unjustified.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment Excerpt Number: 179

Comment: AF&PA recommends that sources be given the flexibility to use emissions averaging provisions or include alternative emission limits for dioxin as well as for PM/TSM, HCl, and mercury. For dioxin, which is a concentration based limit and not a mass based limit, the source would calculate its recommended alternative emission limits using an approach similar to that included in the Pulp and Paper Chemical Recovery Combustion MACT for the PM limits in gr/dscf, and these emission limits would be submitted to the permitting authority for approval and inclusion in the air permit. The alternative emission limits would be set during the initial compliance test. Separate alternative emission limit calculations could be submitted for PM HAP, total metals, mercury and/or HCl at the discretion of the applicant. A site's emissions averaging plan need not include all pollutants; and for any pollutants not specifically included in the emissions averaging plan, the Rule's emissions limitations would apply as a default.
See submittal for equation that could be used to define this averaging methodology:

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.
See response to EPA-HQ-OAR-2002-0058-2694.1, excerpt 6 for developing site specific factor for dioxin/furan.

Comment Excerpt Number: 180

Comment: The proposed rule contains a requirement for the facility to demonstrate each month that the average weighted emissions of the boilers included in the emissions averaging scheme are below the applicable emission limit using the actual heat inputs for that month. AF&PA believes that an annual determination that the emission limits under the emissions averaging approach are being met is more than satisfactory to ensure protection of public health and welfare and appropriate for consideration for a technology-based MACT standard. The first compliance demonstration should not be required immediately after the rule compliance date, as maintenance and outage schedules may make it hard for a facility to comply with the emissions averaging provisions without 12 full months of data. Other rules do not require a monthly test (e.g., the HON), but provide a 30 percent allowance during each quarter and equivalency on an annual basis. Although a year is an appropriate period for determining the time-weighted average emissions rate, consideration may be given for convenience sake to a shorter 6 month period that coincides with the required reporting period for the standard. It is expected that a 6 to 12 month period would provide the flexibility needed to retain the benefit of the recommended averaging provisions.

Response: EPA acknowledges the concerns of the commenter, however the current rule language provisions apply to monthly compliance determinations and are not workable under a different period.

Comment Excerpt Number: 16

Comment: In §IV.L. of the preamble, EPA solicited comments on the proposed emission averaging proposal. Specifically, EPA requested comments on the appropriateness of the discount factor and the provision that emission averaging can not be applied when boilers share a common stack.

DoD recognizes that offset ratios are appropriate for emission trading programs since there are different entities involved and de minimis levels below which no trading is required — the offset ratio in those programs helps compensate for the minor sources for which no offsets are required and helps to ensure that there is always an environmental benefit. In the proposed rule, there are no de minimis thresholds, not even small source or limited use exemptions; emission limits are required for all sources at a major source. As a result, the basis for requiring an offset ratio or discount factor does not apply — it should be sufficient to simply require that the emissions be no higher than the emissions without emission averaging.

Remove the discount factor from equations 1 through 4 of the proposed rule. It should be sufficient to simply require that the emissions are no higher for any pollutant when emission averaging than would be required without emission averaging.

Response: EPA disagrees with the commenter that all units at a major source are subject to emission limits and therefore the discount factor does not apply. Existing small units, limited use units, and units firing gas 1 fuels are not subject to numeric emission limits. See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: DoD facilities tend to have excess capacity and it is not uncommon to have a completely redundant capacity with a different fuel source. This is prudent planning for military facilities and helps ensure that the facility is not vulnerable to sabotage or terrorist acts. With excess capacity, it is not uncommon for multiple boilers to share a common stack. Coal-fired boilers typically use a different fuel for start-up; either natural gas, oil or in the case of stoker boilers —wood. Facilities that use oil for start-up that would like to add a baghouse to control

particulate emissions or dry scrubber systems to control mercury and/or HC1, will most likely change the start-up fuel to natural gas so as to not blank the bags. A new natural gas system may be sufficient to meet demand and may, at times, be less expensive to operate than the coal system. Replacing fuel oil or coal operations with natural gas would reduce the toxic emissions from the facility so it would be advantageous to encourage these modifications. Requiring a separate stack and redundant ducting system, which would be necessary to route the flue gases to a separate stack during alternative fuel operations, would not further environmental aims. As long as the emissions can be individually measured and monitored there should be no need for the emissions to be from separate stacks.
The preamble states that "the emissions averaging provision would not apply to individual units if the unit shares a common stack with units in other subcategories, because in that circumstance it is not possible to distinguish the emissions from each individual unit." This may be true when units in different subcategories are operating at the same time and there is no way to measure individual unit emissions before they reach the common stack. Although the text of the rule does not appear to prevent averaging under all circumstances with units that share stacks with other subcategories, DoD wants to be sure EPA recognizes that units in this situation may still be able to participate in averaging when their emissions can be measured prior to reaching the common stack.

Ensure the final rule does not limit emissions averaging from common stacks shared by more than one subcategory as long as facilities have the capability to monitor emissions for individual units such as in the breeching or ducting leading to the common stack.

Response: See response to comment EPA-HQ-OAR-2002-0058-2694.1, excerpt 3, for how units with common stacks can participate in the emissions averaging provision.

Comment: EPA Fails to Justify the 10 percent Discount Factor for Emissions Averaging. The Proposed Rule 63.7522 allows existing sources to use emission averaging as an alternative compliance mechanism for PM, HCl, and Hg. The soda ash companies, all of whom have more than one unit, support EPA’s decision to allow emission averaging. However, EPA is requiring, for sources that use emissions averaging, the imposition of a 10 percent “discount factor.” 75 Fed. Reg. at 32035. There is no reasonable need or basis for this discount.

EPA’s only justification for the 10 percent discount factor is to “further ensure that averaging will be at least as stringent as the MACT floor limits in the absence of averaging.” Id. EPA provides no data that supports the implication of such statement; that averaging otherwise would allow facilities to emit more HAPs. That simply will not be the case. EPA notes that emissions averaging will only be available for those existing sources that demonstrate that the “total quantity of any particular HAP that may be emitted by that portion of a contiguous major source

. . . will not be great under the averaging mechanism than it could be if each individual affected unit complied separately with the applicable standard.” 75 Fed. Reg. at 32034. EPA continues that this requirement will ensure equivalence to compliance with the MACT floor by “each discrete unit.” Id. By definition, therefore, averaged emissions must be at least as stringent as MACT floor limits in the absence of averaging. Accordingly, there is no reason to impose a 10 percent discount factor on facilities that qualify for emissions averaging, and it should be eliminated.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: Melvin E. Keener
Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)
Document Control Number: EPA-HQ-OAR-2002-0058-2824.1
Comment Excerpt Number: 23

Comment: CRWI supports inclusion of the emission averaging provisions but revisions are needed to expand and improve the usefulness of these provisions.

A. Dioxins/furans should be included.

A source should be allowed to comply with the dioxin/furan (D/F) standard via emission averaging. While CRWI does not believe it is appropriate to set numerical emission standards for D/F, if the final rule does include such numerical standards, a source with multiple units could choose to comply by installing post-combustion control (such as activated carbon injection) to reduce D/Fs on some units. (Note: this example does not imply CRWI believes such technology has been demonstrated on industrial boilers). Since that pollution reduction strategy would justify allowing use of emission averaging for other HAPs, sources should be allowed the same flexibility for dioxins/furans in order to reduce the overall compliance costs for the facility.

B. Carbon monoxide should be included.

Some units may be able to easily meet the proposed CO limits, while, for others, it may impossible. Therefore, CO should be included in the emissions averaging provisions. To facilitate its inclusion, the emission limitation for CO should be expressed in an alternative form — lb/mmBtu. For the case of units using CEMS to measure CO, we reference an existing emission averaging provision for NOx found at 40 CFR 76.11. Heat input should be allowed to be determined using either flow monitors (some units subject to the NOx budget trading program have these already) or using fuel factors and diluent monitors per 40 CFR 60 Method 19.

C. Averaging across subcategories should be allowed.

The proposed emission averaging provision appears to only allow averaging within a subcategory (see 63.7522(a). CRWI believes there is no justification for restricting averaging to a given subcategory. Other MACT standards do not place such restrictions. For example, the

Hazardous Organic NESHAP (40 CFR 63 Subpart G) allows process vents, storage vessels, transfer racks, and wastewater streams to all be included in an emission average across an affected source. This provides a facility the opportunity to avoid otherwise, cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination. In addition, by not allowing averaging across the different fuel types, EPA removes an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from a coal-fired unit.

It is not clear from the proposed rule language if EPA intended to restrict averaging across subcategories. While the wording under the separate stack requirements seems to have this restriction, the wording under the common stack requirements does not (see Equation 6). In any event, as ‘stated above, there should be no such restriction.

As in the HON, the compliance methodology can easily accommodate subcategories with different emission limits for a given pollutant. This is’ done basically by calculating a weighted average allowable mass emission and a weighted average actual mass emission each month using heat inputs or steam production for each unit.

Compliance should be based solely on actual emissions:

The proposed provisions require (1) a demonstration that the average weighted emissions is Tess than 90 percent of the applicable emissions limit assuming each unit is operating at its maximum rated heat input capacity (see Equation 1) and (2) a demonstration each calendar month that the average weighted emissions is less than the applicable emissions limit using the actual heat inputs for that month.

There is no rationale for the first test and it should be eliminated. Other rules that allow emission averaging (again, see the HON), include no such requirement. Such a requirement could be unduly restrictive. For example, a facility may have one older unit and a newer unit which they would like to average. The older unit may have a much lower capacity factor (ratio of actual usage divided by rated capacity) than the newer one. Older units typically have much more space constraints and a facility may be facing steep compliance costs to bring the older unit into compliance and may have an opportunity to over-control the newer unit. Given that the newer unit has a longer remaining life expectancy, such a facility should be incented to over control the newer unit. Yet, Equation 1 may block the facility from taking advantage of the emission averaging flexibility, especially if the older unit has a comparable or even higher rated capacity than the newer unit.

Compliance on a monthly basis during the first twelve months of compliance period is unworkable.

Proposed 63.7522(f)(3) requires a facility to generate enough credits to offset the debits each and every calendar month up until 12 months are accumulated and, thereafter, determine compliance on a twelve month rolling average basis. This requirement unnecessarily restricts the utility of the emission averaging provision. For example, in the case where a facility over-controls one boiler while under-controlling the other, there will be months when the facility could not comply with individual unit limits — even though the facility meets the emission limits on a "facility" basis. This would certainly be true during a month when the credit-generating unit is down for its periodic maintenance outage or during high heating demand months when both units are required at full capacity. Due to the necessary length of these outages (4-6 weeks); there could conceivably be two or three months in a row where the facility could not comply with proposed averaging provisions. There will be other cases where the credit-generating unit experiences an unanticipated outage and the debit-generating unit is required to operate more to compensate. For these reasons, this provision should be eliminated. CRWI notes that the HON, which EPA references, includes an annual emission test along with a quarterly emission test where the average emissions must be less than 130 percent of the allowable emissions. Here, EPA acknowledges that a short term average (quarterly) must provide some tolerance as compared to an annual average. We bring this point'up, not to suggest that EPA adopt the HON quarterly test, but to illustrate that EPA emissions averaging provisions have accounted for this issue. Also, we would note that the HON is written for an entirely different industry than the case of boilers and process heaters. Due to the circumstances described above (extended outages While other units take on additional load or during high heating demand months when both units are required at full capacity), a facility using emissions averaging for boilers and process heaters should be subject to only annual compliance determinations.

The 10 percent penalty for using emissions averaging is arbitrary, unnecessary, and should be removed.

EPA' solicits comment on this discount factor and states that its inclusion further ensures the allowable emissions are, at least as stringent as the MACT floor limits without using averaging. Given the accuracy of heat input weighted emission calculations, CRWI does not see that there is any uncertainty that the average emission rates will be any less stringent than when not using averaging. This discount factor is arbitrary and should be eliminated. Its inclusion reduces the flexibility that the averaging concept provides.

Response: EPA acknowledges the concerns of the commenter, however the current rule language provisions apply to monthly compliance determinations and are not workable under a different period.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 23

Comment: Luminant supports EPA's choice of emissions averaging as an alternative compliance approach. Luminant fully supports the flexibility EPA has provided in the proposed rule to allow emissions averaging. See 75 Fed. Reg. 32,006, 32,034 (June 4, 2010). This approach is reasonable in that it does not result in less stringent standards than the MACT floor limits, provides flexibility, and will reduce costs associated with compliance with the NESHAP.

Response: EPA acknowledges support of the emission averaging provision and has retained the emission averaging provision in the final rule.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 24

Comment: EPA's suggestion of a ten percent discount factor for sources relying on the emissions averaging approach is not supported. EPA does not explain why a discount factor of ten percent is needed. EPA has limited the scope and nature of emissions averaging to ensure that the standard is at least as stringent as the MACT floor. There is no reason for EPA to subject sources to an additional limitation and no public health benefit will be realized. Rather, the ten percent discount factor will ultimately act as a deterrent to emissions averaging. EPA should retain the emissions averaging provision but eliminate the ten percent discount factor.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 36

Comment: Proposed rule §63.7522 and the related explanation in the preamble present the case for being allowed to average PM, HCl, and Hg emissions. This provision is applauded, since it demonstrates an understanding that a multi-boiler, multi-stack facility may be able to achieve and maintain a facility standard as a combination of all stack emissions rather than by each stack individually.

We request that the averaging option extend to CO and D/F compliance. The rational for allowing a facility to average these constituents is the same as that used in the preamble for the other controlled emissions. Namely: "... averaging would not lessen the stringency of the MACT floor limits and would provide flexibility in compliance, cost, and energy savings to owners and operators...." We also agree that the total facility emissions on a pounds per million British thermal units (lb/MMBtu) basis from averaging should be no less stringent than if each unit achieved the MACT floor limits; we only request that CO and D/F be included in the averaging. There is no basis for excluding CO and D/F from emissions averaging, since emissions of these pollutants are directly correlated with HAPs emissions, and emissions averaging would not allow overall facility HAPs emissions to increase.

Response: In the final rule, EPA is requesting only a one-time dioxin/furan testing, and it has modified the CO emission limits and CO compliance mechanisms which are expected to reduce the compliance burden on regulated entities. Further, both CO and dioxin/furan emissions are formed through combustion and not and it is important for the Agency to promote good combustion on all units. Most of the limits are expected to be achieved with good combustion and combustion controls instead of add-on pollution controls and so the concerns with costs of compliance are less than those associated with PM, HCl, and Hg which often require add-on controls to be installed on individual units. In addition, the limits for CO and dioxin/furan in the final rule are established on a concentration (ppm) basis as opposed to a emission factor (lb/mmBtu) basis. As a result, the equations and procedures in the final rule are not applicable to these two pollutants.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 37

Comment: We request that EPA remove the 10 percent penalty and the stipulation that emissions be capped at the value 60 days after the final promulgation of this rule if a facility chooses to comply by the averaging method. The averaging option is attractive and provides an incentive for a facility to engineer creative new control and equipment improvements. If the 10 percent penalty and cap are dropped, overall HAP emissions control will not be less, but will be less costly.

Previously, emission averaging has applied to multi-emission point sources subject to the Hazardous Organic NESHAP (HON) rule in a commonly covered facility such as a petroleum refinery or chemical plant. This rule differs materially in the type of facility and the scope of coverage within a facility. This proposed rule only applies to industrial boilers and process heaters. Boilers and process heaters typically do not have multiple pieces of equipment, vessels, and vents from which to choose optimization of emission control to achieve reductions to reach a facility wide emission limit. Boilers and process heaters have one emission point per unit and sometimes only one emission point for two or more units. Thus, the opportunities for emission reductions via related process equipment and vents do not exist. The 10 percent discount for the averaging method offered by the proposed rule is inappropriate for this MACT.

The proposed penalty and emissions cap and not extending the option to all emission limited pollutants is a disincentive for industry to innovate cost-effective creative emissions reductions for those multi-boiler facilities that might otherwise consider averaging. They also would hold a facility that chooses it to a more stringent standard than its industry contemporaries. This constitutes a capricious, even though perhaps unintended, imposition of a limit beyond the MACT floor on a subset of affected facilities. It is arbitrarily punitive to those facilities that can use averaging and shrinks the number of facilities that might be able to use it; thereby adding unnecessary capital and operating costs.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor. See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 38

Comment: The purpose of this rule is to set MACT standards for HAPs from industrial boilers and process heaters and require industry to meet them. Averaging will encourage customized, creative, and cost efficient techniques and technology for facilities to meet the proposed standards.
In summary:

Proposed equations should be based on actual emissions, and not maximum rated capacity
Additional flexibility reduces cost, especially in case of limited use boilers
Need to be able to use reduced stack testing frequency if using emissions averaging
Need to be able to use the PM CEMS data in averaging equation
Oppose performing monthly compliance for first 12 months

Response: EPA has retained the emission averaging provision in the final rule. See response to EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for additional flexibilities incorporated into the emissions averaging provision.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 204

Comment: Emissions Averaging
CIBO supports inclusion of the emission averaging provisions in the Proposed Rule, but revisions are needed to expand and improve the usefulness of these provisions. 75 FR 32034. Use of emissions averaging would allow owners and operators of an affected source to demonstrate that the source complies with the proposed emission limits by averaging the emission from an individual affected unit that is emitting above the proposed emission limits with other affected units at the same facility that are emitting below the proposed emission limits. 75 FR 32034. EPA further acknowledges that "emissions averaging represents an equivalent, more flexible and less costly alternative to controlling certain emission points to MACT levels" and its application "would not lessen the stringency of the MACT floor limits and would provide flexibility in compliance, cost and energy savings to owners and operators." 75 FR 32034.

EPA has proposed that owners and operators of existing – but not new – affected sources be permitted to demonstrate compliance with the proposed emissions limitations by emissions averaging for units at the affected source that are within a single subcategory. 75 FR 32034.

Under this proposal, emissions averaging could only be used between boilers and process heaters in the same subcategory at a particular affected source. 75 FR 32034.

Response: EPA has retained the emission averaging provision in the final rule. See response to EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for additional flexibilities incorporated into the emissions averaging provision.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 205

Comment: A. The rule should allow for averaging across all subcategories/fuels with emission limits for the pollutant to be averaged.
The proposed emission averaging is explained as allowing averaging only within a subcategory (75 FR 32024) although it is not clear from the Proposed Rule language if this is what EPA intended. See § 63.7522(a), 75 FR 32053. While the wording under the separate stack requirements does seem to have this restriction, the wording under the common stack requirements does not. See Equation 6, 75 FR 32,055. EPA provides no justification for restricting averaging to a given subcategory nor is it rational to impose such a restriction.

EPA states in the preamble that one of its limits on the scope of emissions averaging is to not allow averaging between sources that are not part of the same affected source. 75 FR 32034. In this case, EPA has elected to define the affected source in §63.7490(a)(1) as all units within a subcategory. We see no reason for EPA to use this definition. Rather all units at a given facility subject to the subpart should be collectively considered the "affected source". This is how EPA has defined the term in other rules with which we are familiar (e.g. the HON in Subpart F, Polymer and Resins 4 in Subpart JJJ, the MON in Subpart FFFF). The HON in particular we understand is the model EPA is using to guide its policy. By defining the term affected source as all chemical manufacturing process units (CMPUs) at a facility, the HON allows emissions averaging across CMPUs and across emission unit types (vents, storage vessels, transfer racks, wastewater stream). There is no reason in the boiler and process heater MACT for EPA to restrict the emissions averaging alternative as it has proposed. To do so, will prevent some facilities from taking advantage of the opportunity to avoid otherwise cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination. Also, by not allowing averaging across the different fuel categories, EPA removes an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from a coal-fired unit.

Some affected units involve multiple boilers operating in different subcategories (e.g. stokers and pulverized coal). These boilers are generally located in separate powerhouses. The goal of emissions averaging is to allow facilities to overcontrol some emissions points while undercontrolling others, thus achieving the required reductions in the most cost-effective manner possible. This could be best achieved by EPA removing the restriction (or clarifying its intent) that such averaging would be allowed for all affected units, regardless of whether the boilers emit through separate or "common stacks."

The legal precursor to introducing emissions averaging is Chevron U.S.A., Inc. v. NRDC, 467 U.S. 837 (1984). In Chevron, the Supreme Court held that EPA regulations allowing states to treat all of the pollution-emitting devices within the same industrial grouping as though they were encased within a single "bubble" were based on a reasonable construction by EPA. This case opened the door to more specific emissions averaging efforts, such as those implemented in the 1994 Hazardous Organic NESHAP, 59 FR 19,425 (April 22, 1994)(HON Rule). Several rules have followed the HON Rule in authorizing emissions averaging, and the D.C. Circuit has never invalidated the approach. it does not appear that any such authorizations have succumbed to legal challenge. The proposed emissions averaging provisions in the Boiler Rule are directly based on the emissions averaging provisions in the HON.

In the HON Rule, EPA thoroughly examined the legal basis for emissions averaging, and explored the degree of averaging permitted under §112(d) of the Clean Air Act. At the end of its review, EPA concluded that the Clean Air Act "does not define source category, nor does it impose precise limits on the Administrator's discretion to define source." Id. EPA further acknowledged that the Clean Air Act does not limit how standards are to be set for a category or subcategory beyond requiring that it be applicable to all sources in a category, be written as a numerical limit wherever feasible, and be at least as stringent as the floor. Id.

In promulgating the HON emissions averaging rules, on which the Boiler Rule relies, EPA thus concluded that "the relevant statutory language is broad enough to permit the Administrator to allow sources to meet the MACT through the use of emissions averaging provided the standard applies to every source in the category, averaging does not cross source boundaries, and the standard is no less stringent than the floor." Id. Allowing emissions averaging across subcategories within the Boiler Rule is consistent with the parameters established in the HON rule, and reiterated in the Boiler Rule preamble. See 75 FR at 32,035. Namely, allowing averaging across subcategories will not result in averaging between (a) different types of pollutants, (b) sources that are not part of the same affected source (see other comments above regarding EPA's proposed definition of affected source), (c) individual sources within a single major source if the individual sources are not subject to the same NESHAP, and (d) existing sources and new sources. Id.

There is precedent in MACT standards for allowing averaging across different types of units of a single source. For example, the HON rule allows process vents, storage vessels, transfer racks, and wastewater streams to all be included in an emission average across an affected source. 40 CFR Subpart G. EPA reasoned that averaging needed to be allowed across all emission points (except equipment leaks) in order to provide as much flexibility as possible while maintaining an enforceable emission limitation. 59 FR 19,425. Similar mechanisms have been adopted in other

MACT standards. See, e.g. Petroleum Refinery NESHAP, 60 FR 43244, 43254 (Aug. 18, 1995)(allowing wide range of emission sources to be averaged, noting that "EPA has the flexibility to allow trading within a facility that includes units in different source categories"); Boat Manufacturing NESHAP, 66 FR 44,218; 44,232 (Aug. 22, 2001).

As in the HON, the compliance methodology can easily accommodate subcategories with different emission limits for a given pollutant. This is done basically by calculating a weighted average allowable mass emission and a weighted average actual mass emission each month using heat inputs or steam production for each unit.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcatgories.

Comment: B. The rule should allow for averaging dioxins/furans (D/Fs) and carbon monoxide. The same legal rationale that supports averaging across subcategories, also fully supports emissions averaging for various HAPs. The same policy rationale applies as well: sources should be allowed the flexibility to over-control at some units at a facility and under-control at others in order to reduce the overall compliance costs for the facility, where no increased risk to the environment results. Allowing this averaging is also consistent with the four averaging criteria described in the preamble.

Averaging across subcategories should be permitted for dioxins/furans and carbon monoxide. A source should be allowed to comply with the dioxin/furan (D/F) standard via emission averaging. While it may not be appropriate to set numerical emission standards for D/F, if the final rule does include such numerical standards, a source with multiple units could choose to comply by installing a post-combustion control (such as powder activated carbon injection) to reduce D/Fs on some units at a facility.

Additionally, carbon monoxide should be included in the emissions averaging provision, since some units may be able to easily meet the proposed CO limits, while, for others, it may impossible. To facilitate its inclusion, the emission limitation for CO should be expressed in an alternative form – lb/MMBtu. For the case of units using CEMS to measure CO, we reference an existing emission averaging provision for NOx found at 40 CFR 76.11. Heat input should be allowed to be determined using either flow monitors (some units subject to the NOx budget trading program have these already) or using fuel factors and diluent monitors per 40 CFR 60 Method 19.

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.

Comment: C. The 10% discount factor unless extra flexibility is provided.
EPA imposes a restriction on emissions averaging that requires facilities using that option to meet a standard that is 10% stricter than the otherwise applicable limits. 75 FR 32035. EPA should remove this 10% penalty for using emissions averaging because it is arbitrary, unnecessary for environmental protection and reduces the flexibility that averaging provides. EPA asserts that its inclusion further ensures the allowable emissions are at least as stringent as the MACT floor limits without using averaging. However, EPA offers no demonstration of this in the proposal. Given the accuracy of heat input weighted emission calculations, there is no uncertainty that the average emission rates will be any less stringent than when not using averaging. Because EPA has already determined that the standards in the rule achieve the maximum emission reduction achievable for health and environmental protection, to require an additional 10% reduction of emissions has no basis in the environmental underpinnings of the rule. Because emissions averaging is a compliance alternative, the 10% discount factor constitutes a beyond-the-floor requirement that EPA has not analyzed for its cost, non air quality and energy impacts, as required by CAA §112(d)(2). Finally, although the 10% discount may be perceived as a fair trade-off for the flexibility of emissions averaging, it still lacks a legal basis and creates a disincentive for sources to use this compliance method. Because the proposed limits in this rule are so tight, sources will not be able to ensure an additional 10% reduction in emissions below the limits and imposing this requirement effectively deprives many sources of the availability of the emissions averaging compliance alternative.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: Method for Demonstrating Initial Compliance Should be Amended.
Compliance should be based solely on actual emissions: The proposed provisions require (1) a demonstration that the average weighted emissions is less than 90 percent of the applicable emissions limit assuming each unit is operating at its maximum rated heat input capacity (see Equation 1) and (2) a demonstration each calendar month that the average weighted emissions is less than the applicable emissions limit using the actual heat inputs for that month.

There is no rationale for the first test and it should be eliminated. Other rules that allow emission averaging (again, see the HON), include no such requirement. Such a requirement could be unduly restrictive. For example, a facility may have one older unit and a newer unit which they would like to average. The older unit may have a much lower capacity factor (ratio of actual usage divided by rated capacity) than the newer one. Older units typically have much more space constraints and a facility may be facing steep compliance costs to bring the older unit into compliance and may have an opportunity to over-control the newer unit. Given that the newer unit has a longer remaining life expectancy, such a facility should be incented to over control the newer unit. Yet, Equation 1 may block the facility from taking advantage of the emission averaging flexibility, especially if the older unit has a comparable or even higher rated capacity than the newer unit.

Response: See response to comment EPA-HQ-OAR-2002-0058-3137.1, excerpt 5 for actual vs. design heat input in Equation 1.

Comment: Proposed 63.7522(a) allows for emission averaging within a subcategory for Cl-, PM, and Hg, if your averaged emissions are within 90 percent of the applicable emission limit. We see no justification for the 90% criteria. It certainly represents a beyond-the-floor change to the emission limits that has not been justified. Sources should not be penalized because they want to be efficient in how they reduce emissions. In those cases where a source can be more efficient by over-controlling some sources and not having to control or under-controlling other sources, they should have the right to do so and not be penalized. It will then be their responsibility to assure the average meets the emission limit and to demonstrate compliance and they should bear the risk associated with that choice.

Recommendation: The 10% discount for emission averages should be eliminated.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 228

Comment: Proposed 63.7522(c) contains an antibacksliding provisions that specifies For each existing boiler or process heater in the averaging group, the emission rate achieved during the initial compliance test for the HAP being averaged must not exceed the emission level that was being achieved on [THE DATE 30 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER] or the control technology employed during the initial compliance test must not be less effective for the HAP being averaged than the control technology employed on [THE DATE 30 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER]. However, there is no way to demonstrate compliance because the emission rate on the 30th day after publication of the final rule is not known.

Furthermore, the entire idea is flawed since a source not in an emission average is under no such limit. The emissions from sources not in an emission average may vary anywhere below the emission limit. There is no justification for limiting sources in an emission average differently than sources outside an emission average. If a group of sources can meet the applicable emission limit most efficiently by allowing one of the sources to emit more than it has previously and over-controlling another source, there is no legal or logical justification for not allowing them to do so. Furthermore, the general duty requirement in proposed 63.7505(b) makes clear that source only must reduce emissions to the level of the standard. It rightly does not say sources in an emission average must reduce emissions below the level of the emission limit.
Recommendation: Proposed 63.7522(c) is unenforceable and unreasonable and should be deleted.

Response: 63.7522(c) to state that either the emissions being achieved or the control technology being employed must not be less stringent that the date 60 days after publication of the final rule in the federal register. If sources do not know the emission rate on the 60th day after publication they can document the control technology being employed. For example, if a source has a fabric filter installed on a unit, it cannot remove the fabric filter from the unit and then factor an uncontrolled unit into the emissions averaging calculations. This provision is intended to prevent backsliding of emissions that are currently being achieved before the effective date of the rule.

Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 7

Comment: Duke Energy urges EPA to not institute a discount factor in the final rule as part of the emission averaging alternative compliance provisions
In Section III (L) (32035) EPA solicits comment on its proposed emission averaging proposal. Specifically EPA requested comments on the appropriateness of using a discount factor and whether ten percent is an appropriate value for a discount factor. Duke Energy opposes the use of a discount factor and urges EPA to not include one in the final rule. As a first point, EPA's averaging formula is constructed so that even without a discount factor, the average emissions by a group of units will be no more than what is permitted on an individual basis. Second, Duke Energy is concerned that EPA's proposed IB MACT standards are so low that there are real questions about whether sources can even comply with them while using state-of-the-art control equipment. The net effect is that rather than having a real chance at continued operation, many sources will have no reasonable alternative but to shut down. Third, even if a source can attain the standard, facilities have to operate their units at a level somewhat below a standard so as to ensure an adequate compliance margin. Sources maintain this margin so as to avoid the repercussions of violating an applicable permit limit. A reasonable averaging program can help a group of sources maintain a standard and improves overall compliance. Under EPA's proposal, however, units that normally would be in full compliance with the standard would be in violation just because they attempted to use the averaging program. As an example, a group of units that are all nine percent below the emission standards would be deemed to be in full compliance as individual units. But if a company had elected to place the same units in an averaging program, they would all be judged out of compliance because of the ten percent discount factor. Finally, the choice of 10% appears purely arbitrary and without a specific justification. Another onerous provisions in EPA's proposed averaging program include the required detailed averaging plan a facility would need to prepare and the cap on unit emissions

would not allow any unit participating in the averaging plan to have emission any higher than it had on the effective date of the proposed rule. These too appear to be arbitrary requirements. If EPA is serious about providing operational flexibility to facilities, then it must make substantial revisions to its proposed averaging provisions, including the elimination of the 10% discount factor and unit-level emission caps at historical levels.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: EPA Should Provide More Flexibility for Emissions Averaging

EPA should have proposed an emissions averaging program more in line with what SERs requested rather than the restricted program outlined in the proposal. Emissions averaging is an option for individual facilities that have multiple affected sources on site that saves money and obtains the identical or better emission reductions. By allowing these facilities to average emissions across various affected units, they can focus their investments on the units that will provide the biggest environmental impact per dollar spent, rather than targeting every affected unit to meet a single limit. This approach has the potential to produce a greater emissions reduction than requiring each individual source to meet the standard, while reducing the cost of compliance to the facility, and has been successfully utilized in several proceeding rulemakings. In the proposed rule, EPA limits the flexibility and potential effectiveness of emissions averaging by placing overly strict limitations on a facility's ability to employ averaging.

First, EPA should base the emissions averaging option on actual operating times and emissions rather than on design capacity of affected units. This would have provided more flexibility for facilities that have backup units or other limited use boilers, especially since EPA chose not to create a limited use subcategory. Second, EPA should not have limited the option to encompass only those sources which fall into the same subcategory based on fuel type. This requirement is unnecessarily restrictive and severely limits the flexibility of emissions averaging. Finally, the 10 percent penalty for choosing emissions averaging is again unnecessarily restrictive and again severely limits the flexibility of emissions averaging. Furthermore, EPA waives the penalty for facilities that average across units emitting from the same stack within a facility, despite the fact that the total emissions from units emitting from the same stack are identical to emissions from units emitting from separate stacks as long as all else is held constant.

Advocacy urges EPA to reconsider the emissions averaging option and to remove the impediments to small entities using it as a viable flexibility option that are outlined above, and similar to previous rules adopted by the Agency. EPA should return to the more basic emissions averaging concept that was discussed during the panel and which the panel report unanimously recommended as an important flexibility option.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcategories. See response to comment EPA-HQ-OAR-2002-0058-3137.1, excerpt 5 for actual vs. design heat input in Equation 1. Document Control Number: EPA-HQ-OAR-2002-0058-2755.1
Comment Excerpt Number: 11

Comment: The facility averaging provisions should be modified.

The proposed IB MACT allows emission averaging in certain circumstances. However, the emission averaging provisions of the proposed IB MACT are so restrictive and conditional that they are unlikely to be used. The proposed rule would apply a 10% “discount factor” on any source seeking to average emissions. This discount factor makes no sense and will deter averaging. As noted previously, EPA’s proposed IB MACT standards are so low that there are significant concerns about whether sources can even comply with them using state-of-the-art control equipment. Effectively lowering those standards by 10% for sources that average emissions makes an impossible situation even more impossible. In addition, there is no legitimate reason for imposing a 10% penalty on sources that seek to average emissions. Total emissions from a single facility have the same health effects on public health regardless of whether each unit at the facility meets the MACT limits or all units meet the MACT limits in the aggregate – the 10% penalty on operational flexibility has no public health benefit.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 12

Comment: EPA has proposed to allow emission averaging of HCl, PM, or mercury among existing sources within a plant site under certain conditions. Southern Company agrees with EPA that “averaging represents an equivalent, more flexible, and less costly alternative to controlling certain emission points to MACT levels.” However, we disagree with EPA that the actual averaging provisions represent equivalent or more flexible requirements and believe that the onerous compliance requirements will discourage sources from using averaging.

First, the proposed IB MACT requires that applicable sources with separate stacks must take a 10% “discount factor” in order to participate in averaging. As noted in Section IV of our comments, we are already concerned about our ability to achieve the limits even through the application of the maximum achievable control technology. If the best units have trouble meeting the emission limits, then it will be nearly impossible to over control enough to meet the limits under averaging AND take a 10% discount. Not only do the averaging provisions not provide flexibility to sources trying to comply, but they do not represent “equivalent” limits since they are effectively lowered by 10%. If EPA is serious about providing plant flexibility, then it must reconsider the averaging provisions. It is also noted that the proposed mercury MACT for EGUs, published in the Federal Register on January 30, 2004, did allow averaging of sources “from multiple affected units located at a common, contiguous facility site.” This rule did not require an over compliance of 10% to be able to use facility-wide averaging. Southern Company requests that EPA allow facility-wide averaging consistent with the proposed rule noted above, with no penalty for averaging.

Second, EPA has not explained why averaging is not allowed for the organic HAP, CO and dioxins/furans. Certainly the organic HAP could also benefit from the "equivalent, more flexible, and less costly alternative" of emission averaging. EPA should not only eliminate the discount factor for emission averaging, but should also allow averaging of all applicable emissions.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 30

Comment: AMP supports EPA's use of emissions averaging as a flexible compliance alternative for facilities with multiple units. The Proposed Rule was correct to recognize emissions averaging as an "equivalent, more flexible, and less costly alternative to controlling certain emission points to MACT levels." Id. at 32034. That cost savings and additional flexibility comes at no environmental or health risk since overall emissions will fully comply with the promulgated MACT standards. However, AMP does not support the proposal to apply a "discount factor of ten percent" when emissions averaging is used to "further ensure that averaging will be at least as stringent as the MACT floor limits in the absence of averaging." 75 Fed. Reg. at 32035. This penalty erodes the very compliance flexibility that emissions averaging is designed to create without explaining why any penalty is necessary to uphold the stringency of the MACT floor.

The emissions averaging provisions in the 2004 Boiler MACT rule were substantially similar to those in the current Proposed Rule. Both allowed sources to demonstrate compliance with certain emissions limits by averaging the emissions from one or more existing sources at the same facility that are in the same subcategory. Compare 75 Fed. Reg. at 32053, with 69 Fed. Reg. at 55257. Both required sources utilizing emissions averaging to take the following steps to ensure that implementation for these units would be no less stringent than unit-by-unit implementation: (1) demonstrate that the emission rate achieved during the compliance test does not exceed the emission rate that was being achieved at a set time after publication of the final rule, (2) demonstrate that the control equipment used during the compliance test is no less effective than it was at the same set time, and (3) develop and submit an emissions averaging

implementation plan for approval. Compare 75 Fed. Reg. at 32053, with 69 Fed. Reg. at 5525859.

EPA defended its inclusion of the emissions averaging compliance alternative in the 2004 Boiler MACT rule as follows:

EPA has concluded that it is permissible to establish within a NESHAP a unified compliance regimen that permits averaging across affected units subject to the standard under certain conditions. Averaging across affected units is permitted only if it can be demonstrated that the total quantity of any particular HAP that may be emitted by that portion of a contiguous major source that is subject to the NESHAP will not be greater under the averaging mechanism than it would be if each individual affected unit complied separately with the applicable standard. Under this rigorous test, the practical outcome of averaging is equivalent in every respect to compliance by the discrete units, and the statutory policy embodied in the MACT floor provisions is, therefore, fully effectuated. [Footnote: Memorandum from Jim Eddinger, ESD Combustion Group, to Robert Wayland, ESD Combustion Group, re: Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP (Feb. 25, 2004) (EPA-HQ-OAR-2002-0058-0611).]

The 2004 Boiler MACT rule did not contain any penalty provisions for emissions averaging, concluding that the safeguards enumerated above were sufficient. EPA has offered no explanation for why these steps are insufficient in 2010 or why a penalty of 10% is necessary to uphold the MACT floor for all sources. Nor did the intervening D.C. Circuit court decision offer any input on this topic. EPA is required to provide a "reasoned explanation . . . for disregarding facts and circumstances that underlay . . . prior policy." FCC, 129 S. Ct. at 1810. EPA’s decision to include a penalty provision in the Proposed Rule, given its prior defense of emissions averaging absent such a provision, is arbitrary and capricious.

Response: EPA determined that the discount factor is necessary in order to ensure that the emissions under an emissions averaging provision will be at least as stringent as the rule without averaging. The legal basis and rational for the HON emissions averaging provisions and the discount factor were provided in the preamble to the final HON (59 FR 19425, April 22, 1994).

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 64

Comment: The proposed rule requires that a source establish emissions limits for each unit participating in the emissions averaging plan based on the emissions levels achieved during the initial compliance test. These proposed unit-specific "emissions caps" impose additional and unnecessary stringency in the ongoing compliance procedures. In addition, they do not allow the source to benefit from added operating flexibility if additional emissions controls are added to lower emitting units. RMB notes that the source will continue to maintain average emissions below the emissions standard during each subsequent compliance test regardless of the caps or risk eliminating one or more units from the averaging group.

The proposed rule also applies a ten percent "discount" factor to the average calculated emissions in assessing compliance with the emissions standards. This "discount factor" is an unnecessary penalty that effectively increases the stringency of the emissions standards and reduces the utility of the averaging provisions.

As noted in the vacated IB-MACT Rule, emissions averaging was included to provide greater compliance flexibility particularly for smaller, municipal electric utilities. The proposed use of emissions caps and penalty factors reduce the overall benefit of the emissions averaging and reduce the flexibility in demonstrating compliance for these sources. Given the stringency of the proposed standards, RMB recommends that EPA consider eliminating these requirements from the emissions averaging provisions.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor. See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 228 for clarification of the anti-backsliding procedures.

Comment Excerpt Number: 2

Comment: We agree that incorporating emissions averaging into the Boiler MACT is a proper way to encourage flexibility and cost savings for affected facilities. There is ample precedent in the MACT program for allowing emissions averaging. For example, the Pulp and Paper Chemical Recovery Combustion MACT allows plants to set a PM HAP emissions limit for each existing applicable process unit such that, if these limits are met, the total emissions from all existing process units are less than or equal to a "bubble" limit on all affected units. See 66 Fed. Reg. 3180, 3184 (January 13, 2001) and 40 C.F.R. Part 63, Subpart MM. See also 67 Fed. Reg. 78046 (December 20, 2002) (proposing emissions averaging in the Lime Manufacturing MACT). Many other MACT standards have included emissions averaging provisions, which are conceptually similar. See, e.g., 40 C.F.R. Part 63, Subpart JJJ (Group IV Polymers and Resins); 40 C.F.R. Part 63, Subpart U (Group I Polymers and Resins); 40 C.F.R. Part 63, Subpart G (Synthetic Organic Chemical Manufacturing Industry: Process Vents, Storage Vessels, Transfer Operations and Wastewater); 40 C.F.R. Part 63, Subpart LL (Primary Aluminum Reduction Plants); 40 C.F.R. Part 63, Subpart CC (Petroleum Refineries); 40 C.F.R. Part 63, Subpart EEE (Hazardous Waste Combustors).

Emissions averaging is a well demonstrated technique for meeting or exceeding environmental objectives at lower cost and with greater flexibility tailored to individual affected facilities. Provisions such as these allow plants to optimize their investments by installing controls on units where the lowest emission rates can be achieved in the most cost-effective manner possible. For example, a source could decide to over-control a newer unit in order to avoid costly investments in an older unit that may be retired before the useful life of the control device is reached. Emissions averaging provisions also provide environmental benefit by allowing for control options that minimize energy use. Energy efficient decisions benefit the environment by reducing power demands and the secondary pollutant impacts they generate.

WC concurs with EPA’s proposal and past precedent that use of the emissions averaging compliance alternative would be limited to existing units. New and reconstructed boilers/process heaters would be required to meet the more stringent "new source" requirements.

Comment: One of SABIC’s major sources operates four coal-fired boilers. Two are stoker design coal-fired boilers emitting through one common stack. The other two are pulverized coal-fired units emitting through another, different common stack.

The proposed 63.7522 emission averaging provisions do not allow averaging of emissions from all existing boilers that are in different subcategories venting to separate stacks. Paragraph 63.7522(b) provides emission averaging for a group of two or more existing boilers in the same subcategory that each vent to a separate stack. Paragraphs 63.7522(h) and (j) provide emissions averaging for units in different subcategories venting through a common stack. However,

although the emission limits for particulate matter, HC1, and mercury for the pulverized coal and stoker coal subcategories are the same, there is no provision for emission averaging among pulverized coal units emitting through a common stack with emissions from stoker coal units emitting through another common stack. This would prohibit SABIC from averaging the emissions from its two groups of boilers, one of which is a pair of stoker coal units and the other of which is a pair of pulverized coal units.
We do not understand why the rule should prohibit emission averaging for a group of two or more existing coal-fired boilers in different subcategories when all coal-fired boilers must meet the same particulate matter, HCI, and mercury emission limits, regardless of stack configuration. The final rule should allow averaging such emissions to demonstrate compliance with the common emission limits.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcatgories. See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.

Comment Excerpt Number: 3

Comment: We believe that additional flexibility should be incorporated into the proposed emissions averaging provisions in order to ensure facilities have options to reduce the cost of compliance. The emissions averaging provisions should be based on actual operating time and emissions and not capacity. Adding the element of time ensures equivalent control regardless of boiler operating schedules and provides flexibility with respect to the control strategy for limited use boilers. Some boilers are only used during maintenance outages, and incorporating flexibility into the emissions averaging provisions to accommodate limited use boilers will greatly reduce the compliance cost for these boilers. Boilers sharing common stacks should also be eligible for inclusion in the emissions averaging approach, especially if emissions can be measured from each boiler prior to the common stack. EPA has included all common stack units in its MACT floor analyses by applying the measured common emission rate to each unit, instead of one time for the group of units, so this approach could also be used in an emissions averaging compliance scenario.

Response: In the final rule limited use boilers are not subject to numeric emission limits. Therefore, we determined that additional flexibility of modifying the heat input parameter in equation 1 is not necessary.

Boilers venting to a common stack are eligible for emissions averaging as long as they are in the same subcategory. See 63.7522(k)

Comment: Glatfelter believes that boilers of any design firing any fuel (e.g., in any subcategory) should be included in the emissions averaging provisions and that facilities should not be limited to use of emissions averaging only for boilers in the same subcategory. There is no justification for restricting emissions averaging only to boilers in a specific subcategory; facilities should be able to average emissions from stoker boilers with emissions from pulverized coal boilers and liquid boilers. This approach has been used in several of the other rules mentioned above. For example, the Pulp and Paper Chemical Recovery Combustion MACT and the HON allow emissions averaging across different types of units. The equivalency by permit provisions under 40 CFR 63.94 allow sources to "trade" emissions from unregulated sources for emissions of regulated sources, so this is additional reason not to restrict use of emissions averaging to boilers within the same subcategory.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for response on averaging across different subcategories.

Comment Excerpt Number: 4

Comment: Averaging emissions from different subcategories would be consistent with emissions averaging provided in other MACT standards. For example, pursuant to 40 CFR 63.112(t), the Hazardous Organic NESHAP (HON) allows controlling some of the emission points (e.g., individual process vents, storage vessels, transfer racks, wastewater streams) within the source to different levels than specified in 63.113 through 63.148 by using an emissions averaging compliance approach, as long as the overall emissions from the source do not exceed the emission level specified in § 63.112(a). Similarly, the NESHAP for Miscellaneous Organic Chemical Manufacturing (MON) allows emissions averaging among different emission points pursuant to 40 CFR 63.2500. Paragraph 63.2500(b) additionally provides that the batch process vents are collectively considered one individual emission point for the purposes of emissions averaging.

In addition, 63.7522 of the vacated Subpart DDDDD MACT previously provided SABIC the option to use emission averaging of the emissions from each of the two common stacks serving its four large solid fuel-fired boilers to demonstrate compliance with the common particulate, HC1, or mercury limits applicable to the four boilers.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for response on averaging across different subcategories.
See response to comment EPA-HQ-OAR-2002-0058-2694.1, excerpt 3, for response of how units with common stacks can participate in the emissions averaging provision.

Comment: We request that § 63.7522 provide for demonstrating compliance by averaging emissions from a common stack through which one or more pulverized coal boilers emit with emissions from a common stack through which one or more stoker coal boilers emit. One way to provide this would be to amend proposed § 63.7522 as follows (additions underlined in bold; deletions bold strike-through):
(a)(1)As an alternative to meeting the requirements of § 63.7500 for particulate matter, HC1, or mercury on a boiler or process heater-specific basis, if you have more than one existing boiler or process heater in any subcategory located at your facility, you may demonstrate compliance by emission averaging, if your
averaged emissions are within 90 percent of the applicable emission limit, according to the procedures in this section.
(2) For the purposes of emissions averaging, you may elect to deem boilers
or process heaters in separate subcategories located at the same major source to be in the same subcategory for those pollutants for which Table 2 to this subpart has the same emission limit for the separate subcategories. In such case, the emission limit applicable to the boilers or process heaters shall be the same emission limit.
To document the election, the implementation plan requirements in 63.7522(g)(2) should be amended.
(g) ***
(1) ***
(2) You must include the information contained in paragraphs (g)(2)(i) through (vii) of this section in your implementation plan for all emission sources included in an emissions average:
(i) The identification of all existing boilers and process heaters in the averaging group, including for each either the applicable HAP emission level or the control technology installed as of [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER], and the date on which you are requesting emission averaging to commence and, for an election pursuant to 463.7522(a)(2), the identification of any existing boilers or process heaters and the subcategory you are electing to deem them;
In addition, § 63.7522(g)(4) should be changed to clarify authority to approve an emission averaging implementation plan. A proposed change to § 63.7522(g)(4) follows:
(4) The applicable regulatory authority shall not approve an emission averaging implementation plan containing any of the following provisions:
(i) Any averaging between emissions of differing pollutants or between differing sources; or
(ii) The inclusion of any emission source other than an existing unit in the same subcategory.

For purposes of emission averaging, boilers or process heaters that are deemed to be in the same subcategory pursuant to § 63.7522(a)(2) shall not
be deemed to be a differing source or to be in a different subcategory.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcatgories.

Comment Excerpt Number: 5

Comment: We disagree that a 10 percent penalty for use of emissions averaging is appropriate. This requirement restricts the utility of the proposed emissions averaging provisions, especially as this demonstration is proposed to be based on unit capacity and not actual unit operating data. The Pulp and Paper Chemical Recovery Combustion MACT allows averaging of emissions with no requirement to further reduce emissions to 90 percent of the allowable emission rate.

We believe that the application of the underlying principles of emissions averaging, as stated in the Proposed Rule, is sufficient to ensure full realization of the statutory requirements of meeting the MACT standards for the affected sources and that no discount factor is required. EPA fails to justify the necessity to further tighten emissions standards when emissions averaging is used. This point is further reinforced by the fact that EPA expressly excluded the provisions of emissions averaging, including the discount factor, to a situation where individual units are vented through a common stack. EPA must realize that there is no difference in actual emissions between two units emitting from separate stacks and the same units, operated in an identical fashion, emitting from a common stack: the quantity of contaminants emitted to the atmosphere will be identical in both circumstances and imposing a discount factor to the units emitting separately will surely discourage any facility from using this compliance option. EPA bases its justification for including of a discount factor on the emissions averaging provisions in the Hazardous Organic NESHAP (HON), stating that the legal basis and rational for the HON emissions averaging provisions have been provided in the preamble to the final HON.[59 FR 19425, April 22, 1994] However, EPA dismisses this discount provision in the preamble to the proposed NESHAP rule for Plywood and Composite Wood Products (PCWP MACT), stating "...(the) HON sources have many emission points, are complex and diverse, and as a result are subject to a more complex set of emissions averaging provisions. The PCWP facilities have fewer emission points within each facility. Therefore, the enforcement concerns arising due to the large number of emission points in each HON facility are minimized for PCWP facilities."[68 FR 1290, January 9, 2003] EPA concludes its argument to dismissing a discount factor for PCWP sources by stating that "...(the) HON requires a discount factor of 10 percent in credit calculations to share with the environment some portion of the cost savings due to emissions averaging and to account for uncertainty in emissions estimation. Due to differences between PCWP and HON sources (discussed below), we do not believe it is necessary for the proposed PCWP rule to include a discount factor. "[68 FR 1290, January 9, 2003]. This conclusion was maintained in the final version of the PCWP MACT Rule[69 FR 45973, July 20, 2004]. In fact, the concept of imposing a discount factor on the use of emissions averaging was never discussed neither in the initially proposed [17 68 FR 1660, January 13, 2003] nor the previous final[69 FR 55218, September 13, 2004] Boiler MACT Rule. Hence we believe that imposing a discount factor to the emissions averaging compliance alternative is unwarranted and unjustified.

Response: We acknowledge the counter-rationale provided by the PWCP rulemaking, however see response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: Glatfelter recommends that sources be given the flexibility to use emissions averaging provisions or include alternative emission limits for dioxin as well as for PM/TSM, HCI, and mercury. For dioxin, which is a concentration based limit and not a mass based limit, the source would calculate its recommended alternative emission limits using an approach similar to that included in the Pulp and Paper Chemical Recovery Combustion MACT for the PM limits in gr/dscf, and these emission limits would be submitted to the permitting authority for approval and inclusion in the air permit. The alternative emission limits would be set during the initial compliance test. Separate alternative emission limit calculations could be submitted for PM HAP, total metals, mercury and/or HCI at the discretion of the applicant. A site's emissions averaging plan need not include all pollutants; and for any pollutants not specifically included in the emissions averaging plan, the Rule's emissions limitations would apply as a default.

[See submittal for an equation such as the following could be used to define this averaging methodology]

Comment: EPA Should Provide More Flexibility for Emissions Averaging

EPA should have proposed an emissions averaging program more in line with what SERs requested rather than the restricted program outlined in the proposal. Emissions averaging is an option for individual facilities that have multiple affected sources on site that saves money and obtains the identical or better emission reductions. By allowing these facilities to average emissions across various affected units, they can focus their investments on the units that will provide the biggest environmental impact per dollar spent, rather than targeting every affected unit to meet a single limit. This approach has the potential to produce a greater emissions reduction than requiring each individual source to meet the standard, while reducing the cost of compliance to the facility, and has been successfully utilized in several proceeding rulemakings. In the proposed rule, EPA limits the flexibility and potential effectiveness of emissions averaging by placing overly strict limitations on a facility’s ability to employ averaging.

First, EPA should base the emissions averaging option on actual operating times and emissions rather than on design capacity of affected units. This would have provided more flexibility for facilities that have backup units or other limited use boilers, especially since EPA chose not to create a limited use subcategory. Second, EPA should not have limited the option to encompass only those sources which fall into the same subcategory based on fuel type. This requirement is unnecessarily restrictive and severely limits the flexibility of emissions averaging. Finally, the 10 percent penalty for choosing emissions averaging is again unnecessarily restrictive and again severely limits the flexibility of emissions averaging. Furthermore, EPA waives the penalty for facilities that average across units emitting from the same stack within a facility, despite the fact that the total emissions from units emitting from the same stack are identical to emissions from units emitting from separate stacks as long as all else is held constant.

Advocacy urges EPA to reconsider the emissions averaging option and to remove the impediments to small entities using it as a viable flexibility option that are outlined above, and similar to previous rules adopted by the Agency. EPA should return to the more basic emissions averaging concept that was discussed during the panel and which the panel report unanimously recommended as an important flexibility option.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcatgories. See response to comment EPA-HQ-OAR-2002-0058-3137.1, excerpt 5 for actual vs. design heat input in Equation 1.

Commenter Name: Ann W. McIver
Commenter Affiliation: Citizens Energy Group
Document Control Number: EPA-HQ-OAR-2002-0058-2875.1
Comment Excerpt Number: 6

Comment: As proposed, the use of emissions averaging is limited to units in the same designated subcategories. Citizens would like to encourage EPA to allow averaging across subcategories (of the same fuel) in order to allow facilities to make cost-effective investments in technologies and other strategies designed to achieve the reductions required under this regulation. In many cases, especially with the facilities that are likely subject to the proposed rules, the geographical location of the physical plant may be located in a congested area of the site that will not readily accommodate installation of control technologies. However, these same facilities may have the ability to "over-comply" on one or more emission units in order to ensure the environmental benefits are realized.

Recognizing that not all subcategories have identical emission limits under this proposed rule, Citizens believes that the provisions of 40 CFR 76.11, Emissions Averaging provisions under the Acid Rain Nitrogen Oxides Emissions Reduction Program, provides a model that sources may be able to use to ensure the environmental benefits are achieved.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcategories.

Comment: The proposed rule contains a requirement for the facility to demonstrate each month that the average weighted emissions of the boilers included in the emissions averaging scheme are below the applicable emission limit using the actual heat inputs for that month. Glatfelter believes that an annual determination that the emission limits under the emissions averaging approach are being met is more than satisfactory to ensure protection of public health and welfare and appropriate for consideration for a technology-based MACT standard. The first compliance demonstration should not be required immediately after the rule compliance date, as maintenance and outage schedules may make it hard for a facility to comply with the emissions averaging provisions without 12 full months of data. Other rules do not require a monthly test (e.g., the HON), but provide a 30 percent allowance during each quarter and equivalency on an annual basis. Although a year is an appropriate period for determining the time-weighted average emissions rate, consideration may be given for convenience sake to a shorter 6 month period that coincides with the required reporting period for the standard. It is expected that a 6 to 12 month period would provide the flexibility needed to retain the benefit of the recommended averaging provisions.

Response: See response to EPA-HQ-OAR-2002-0058-3213.1, excerpt 180 for response to comment on monthly compliance determinations.

Comment: We disagree with EPA's assertion that a 10% "discount factor" for emissions averaging "will further ensure that averaging will be at least as stringent as MACT floor limits in the absence of averaging." Averaged MACT sources that meet the MACT limitation are, by definition, as stringent as the MACT limitation in question; if the EPA does not believe that any source should ever exceed the emission limitation regardless of ability to average, then averaging would not be a viable proposal. We must conclude that the EPA is proposing a beyond the floor analysis, in which case an economic analysis is required.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: The proposed IB MACT rule allows emission averaging in certain circumstances. While emission averaging can, in theory, provide operational flexibility to sources, the emission averaging provisions of the proposed rule are so restrictive and highly conditioned that they are unlikely to be used. The proposed rule would apply a 10% "discount factor" on any source seeking to average emissions. This discount factor makes no sense and will deter averaging. As previously noted, EPA's proposed IB MACT standards are so low that there are real questions about whether sources can comply with them using state-of-the-art control equipment. Effectively lowering those standards by 10% for sources that choose to average emissions makes an impossible compliance situation even worse. Also, there is no legitimate reason for imposing a 10% penalty of sources that seek to average emissions. Total emissions from a single facility have the same health effects on public health regardless of whether each unit at the facility meets the MACT limits or all units meet the MACT limits in the aggregate -- the total emissions from the facility remain the same. The proposed 10% penalty on operational flexibility yields no public heath benefits.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: Lee B. Zeugin

Document Control Number: EPA-HQ-OAR-2002-0058-2840.1
Comment Excerpt Number: 22

Comment: Because the 90 percent emissions limit is arbitrary, EPA must allow straight emissions averaging across existing sources within the same source category.

Compliance with emission limits should be based solely on actual emissions as has been the case with previous MACT rulemaking. The proposed provisions require (1) a demonstration that the average weighted emissions are less than 90 percent of the applicable emissions limit assuming each unit is operating at its maximum rated heat input capacity, and (2) a demonstration each calendar month that the average weighted emissions is less than the applicable emissions limit using the actual heat inputs for that month.

The 90% factor is baseless and should be eliminated. The existing NESHAP regulations (HON and MON, for example) provide for straight emission averaging without an arbitrary 90% factor, and EPA has provided no justification for imposing the 90% factor.

In addition, there is no justification for imposing emission standards calculated by two compliance methods for the same equipment. Averaging of emissions based on actual heat input is the technically correct methodology.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: Emissions averaging across categories should be allowed

In the proposed rule, the use of emissions averaging is limited to units in the same designated subcategories. IDEA encourages EPA to allow averaging across subcategories, thereby allowing facilities to make cost-effective investments in technologies and other strategies designed to achieve the reductions required under this regulation. In many facilities that are likely subject to the proposed rules, some plant equipment may be located in a congested area of the site in which it is difficult or impossible to install control technologies. On the other hand, other equipment at the same site may have space and the cost-effective ability to “over-comply” on one or more emission units in order to ensure the overall reductions are achieved.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for response on averaging across different subcategories.

Comment: EPA proposes that a discount factor be applied when facilities choose to comply with the standard by averaging the emissions of their various sources. Both the presence of a discount factor and the value selected by EPA are unreasonable. When the proposed standard is already a daily or monthly average, discounting is unnecessary. Any data collection-oriented deviations the discount factor may be designed to prevent are already balanced out by the daily and monthly averages of each source. It is unclear, therefore, how a discount factor contributes to the accuracy of the facility's compliance status.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: The emissions averaging option is not allowed in the proposed rule for dioxins and furans emissions, which U.S. Sugar feels is not an effective use of this alternative compliance option since the option would have the most benefit for the dioxins and furans emission limits as these pollutants do not have extensive histories with control options (or test data).

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging.

Comment: EPA is proposing conflicting rules, as facilities whose sources emit to a common stack will not be subject to the discount factor. This proposal unjustifiably incentivizes the use of a common stack. Providing such a competitive advantage to certain facilities without good reason undermines the legitimacy of the proposal.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor. EPA has developed several compliance flexibilities in this rule, and treatment of common stacks and the emissions averaging provision are two of such compliance flexibilities. Facilities whose sources vent to a common stack and want to use the emissions averaging provision are also subject to the discount factor. Facilities that opt to comply with the provisions set forth for common stacks without using emissions averaging are not subject to a discount factor. The requirements and language of the common stack option are a result of an earlier focused Agency reconsideration and the resulting public comments received on that reconsideration (See 71 FR 70651). The common stack introduces testing flexibility since testing emissions from a common stack for a group of boilers would be equivalent to the average emissions calculated from individual stack tests on each unit contributing to the stack emissions. Testing once per stack reduces the testing costs associated with boilers venting to the same stack. The scope of applicable sources is very narrow since not all units at a facility vent to a common stack. The emissions averaging option introduces a broader compliance flexibility, and since some units may opt to over control some sources while undercontrolling other sources in order to stategically allocate capital for control devices. EPA determined that given prior precedence for a discount factor in emissions averaging situations, and the broader impact emission averaging has on similar units across a facility, that a discount factor remains appropriate. Further, in many cases EPA notes that more than one of these compliance flexibilities is available to regulated entities.

Comment: The discount value of 10% proposed by EPA is excessive. Although there is no basis for any discount factor, if EPA determines one should be imposed, a more reasonable value should be considered. EPA has provided no justification for its selection of 10% and has provided no indication of what its specific concerns are in the averaging process. Any statistical anomalies that could hypothetically result from averaging could be eliminated by a smaller discount factor. The 10% discount factor reduces an already determined slim compliance margin regarding the PM emission limit for U.S. Sugar's existing Boiler Nos. 7 and 8 based on historical compliance testing for each unit. As previously identified, Boiler No. 7 was utilized by EPA in establishing the MACT Floor so it would be assumed that the unit can meet the PM emissions limit as it would be "achieved under the worst foreseeable circumstances." Furthermore, Boiler No. 8 is the newest unit at the Clewiston facility and was designed to meet the previous version of the Boiler MACT emission limitations. Even with these two controlled boilers, the emissions averaging is not a viable option based on historical compliance testing data when combining with the other similar source units (Boiler Nos. 1, 2, and 4) PM compliance testing data.

Emissions averaging is clearly a permissible application of the emission limitations standards. See 59 Fed. Reg. 19,402, 19,425 (Apr. 22, 1994). Its use allows facilities some flexibility in choosing the means for reducing their emissions, thereby reducing some of the economic burden, while still accomplishing EPA's goal of establishing more stringent emission limits. EPA's use of a discount factor, particularly one as high as 10%, unreasonably interferes with companies' ability to find the most efficient means (from both an economic and environmental perspective) to comply with the emission limits.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: ACCCI supports EPA's use of emissions averaging as a flexible compliance alternative for facilities with multiple units. The Proposed Rule was correct to recognize emissions averaging as an "equivalent, more flexible, and less costly alternative to controlling certain emission points to MACT levels." Id. at 32034. That cost savings and additional flexibility comes at no environmental or health risk since overall emissions will fully comply with the promulgated MACT standards. However, ACCCI does not support the proposal to apply a "discount factor often percent" when emissions averaging is used to "further ensure that averaging will be at least as stringent as the MACT floor limits in the absence of averaging." 75 FR at 32035. This penalty erodes the very compliance flexibility that emissions averaging is designed to create without explaining why any penalty is necessary to uphold the stringency of the MACT floor.

The emissions averaging provisions in the 2004 Boiler MACT Rule were substantially similar to those in the current Proposed Rule. Both allowed sources to demonstrate compliance with certain emissions limits by averaging the emissions from one or more existing sources at the same facility that are in the same subcategory. Compare 75 FR at 32053, with 69 FR at 55257. Both required sources utilizing emissions averaging to take the following steps to ensure that implementation for these units would be no less stringent than unit-by-unit implementation: (1) demonstrate that the emission rate achieved during the compliance test does not exceed the emission rate that was being achieved at a set time after publication of the final rule, (2) demonstrate that the control equipment used during the compliance test is no less effective than it was at the same set time, and (3) develop and submit an emissions averaging implementation plan for approval. Compare 75 FR at 32053, with 69 FR at 55258-59.
EPA defended its inclusion of the emissions averaging compliance alternative in the 2004 Boiler MACT Rule as follows:
EPA has concluded that it is permissible to establish within a NESHAP a unified compliance regimen that permits averaging across affected units subject to the standard under certain conditions. Averaging across affected units is permitted only if it can be demonstrated that the total quantity of any particular HAP that may be emitted by that portion of a contiguous major source that is subject to the NESHAP will not be greater under the averaging mechanism than it would be if each individual affected unit complied separately with the applicable standard. Under this rigorous test, the practical outcome of averaging is equivalent in every respect to compliance by the discrete units, and the statutory policy embodied in the MACT floor provisions is, therefore, fully effectuated.
The 2004 Boiler MACT Rule did not contain any penalty provisions for emissions averaging, concluding that the safeguards enumerated above were sufficient. EPA has offered no

explanation for why these steps are insufficient in 2010, or why a penalty of 10% is necessary to uphold the MACT floor for all sources. Nor did the intervening D.C. Circuit court decision offer any input on this topic. EPA is required to provide a “reasoned explanation ... for disregarding facts and circumstances that underlay ... prior policy.” FCC v. Fox Television Stations, Inc., 129 S. Ct. at 1810. EPA’s decision to include a penalty provision in the Proposed Rule, given its prior defense of emissions averaging absent such a provision, is arbitrary and capricious. [Footnote 17: Memorandum from Jim Eddinger, ESD Combustion Group, to Robert Wayland, ESD Combustion Group, re: Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP (Feb. 25, 2004) (EPA-HQ-OAR-2002-0058-0611).]

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: Emission averaging. EPA’s proposed discount factor of ten percent to be applied when emission averaging is used appears to be contrary to one of EPA’s stated reasons for proposing averaging, namely, “...to give existing sources flexibility to achieve compliance at diverse points with varying degrees of add-on control already in place in the most cost-effective and technically reasonable fashion.”

The application of a 10% discount factor for emissions averaging is inappropriate as it penalizes cost-effectiveness and flexibility to achieve compliance.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: The NC DAQ supports the use of emissions averaging without the application of a 10% discount factor. In the proposed rule, EPA indicates that the “discount factor will further ensure that averaging will be last as stringent as the MACT floor limits in the absence of averaging.” NC DAQ believes that the testing, monitoring, and recordkeeping in the proposed rule is sufficient to determine whether the emissions from a group of individual units is unnecessary to achieve the goals the MACT standard, and it discourages facilities from utilizing this compliance option that could otherwise provide improved flexibility and cost savings to American industry.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: The proposed emission averaging is explained as allowing averaging only within a subcategory (75 Fed.Reg. at 32,034) although it is not clear from the proposed rule language if this is what EPA intended. See § 63.7522(a), 75 Fed.Reg. at 32,053. While the wording under the separate stack requirements does seem to have this restriction, the wording under the common stack requirements does not. See Equation 6, 75 Fed.Reg. 32,055. EPA provides no justification for restricting averaging to a given subcategory nor is it rational to impose such a restriction.
Some affected units involve multiple boilers operating in different subcategories (e.g. stokers and pulverized coal). These boilers are generally located in separate powerhouses. The goal of emissions averaging is to allow facilities to more tightly control some emissions points while applying fewer controls to others, thus achieving the required emission limitations in the most cost-effective manner possible. This could be best achieved by EPA removing the restriction (or clarifying its intent) that such averaging would be allowed for all affected units, regardless of whether the boilers emit through separate or "common stacks." The rule should allow for averaging across all solid fuel units (coal or biomass) regardless of category of pollutants to be averaged so long as emissions from a single unit can be quantified with testing either in the breeching or in the stack when other units aren't operating.
Allowing averaging across subcategories within the rule is consistent with the four averaging criteria described in the preamble:

1-No averaging between different types of pollutants,
2-No averaging between sources that are not part of the same affected source,
3-No averaging between individual sources within a single major source if the individual sources are not subject to the same NESHAP, and
4- No averaging between existing sources and new sources. 75 Fed.Reg. 32035.

Thus, averaging across subcategories is a possible interpretation of the proposal, and EPA could revise this in the final rule.

The legal precursor to introducing emissions averaging is Chevron U.S.A., Inc. v. NRDC, 467 U.S. 837 (1984). In Chevron, the Supreme Court held that EPA regulations allowing states to treat all of the pollution-emitting devices within the same industrial grouping as though they were encased within a single "bubble" were based on a reasonable construction by EPA. This case opened the door to more specific emissions averaging efforts, such as those implemented in the 1994 Hazardous Organic NESHAP, 59 Fed.Reg. 19,425 (April 22, 1994)(HON Rule). Several rules have followed the HON Rule in authorizing emissions averaging, and the D.C.

Circuit has never invalidated the approach. it does not appear that any such authorizations have succumbed to legal challenge. The proposed emissions averaging provisions in the Boiler Rule are directly based on the emissions averaging provisions in the HON.

In the HON Rule, EPA thoroughly examined the legal basis for emissions averaging, and explored the degree of averaging permitted under §112(d) of the Clean Air Act. At the end of its review, EPA concluded that the Clean Air Act "does not define source category, nor does it impose precise limits on the Administrator's discretion to define source." Id. EPA further acknowledged that the Clean Air Act does not limit how standards are to be set for a category or subcategory beyond requiring that it be applicable to all sources in a category, be written as a numerical limit wherever feasible, and be at least as stringent as the floor. Id.
In promulgating the HON emissions averaging rules, on which the Boiler Rule relies, EPA concluded that "the relevant statutory language is broad enough to permit the Administrator to allow sources to meet the MACT through the use of emissions averaging provided the standard applies to every source in the category, averaging does not cross source boundaries, and the standard is no less stringent than the floor." Id. Allowing emissions averaging across subcategories within the Boiler Rule is consistent with the parameters established in the HON rule, and reiterated in the Boiler Rule preamble. See 75 Fed.Reg. at 32,035. Namely, allowing averaging across subcategories will not result in averaging between (a) different types of pollutants, (b) sources that are not part of the same affected source, (c) individual sources within a single major source if the individual sources are not subject to the same NESHAP, and (d) existing sources and new sources. Id. at 32,034.

There is precedent in MACT standards for allowing averaging across different types of units of a single source. For example, the HON rule allows process vents, storage vessels, transfer racks, and wastewater streams to all be included in an emission average across an affected source. 40 CFR Subpart G. EPA reasoned that averaging needed to be allowed across all emission points (except equipment leaks) in order to provide as much flexibility as possible while maintaining an enforceable emission limitation. 59 Fed.Reg. 19,425. Similar mechanisms have been adopted in other MACT standards. See, e.g. Petroleum Refinery NESHAP, 60 Fed.Reg. 43244, 43254 (Aug. 18, 1995)(allowing wide range of emission sources to be averaged, noting that "EPA has the flexibility to allow trading within a facility that includes units in different source categories"); Boat Manufacturing NESHAP, 66 Fed.Reg. 44,218; 44,232 (Aug. 22, 2001).
As in the HON, the compliance methodology can easily accommodate subcategories with different emission limits for a given pollutant. This is done basically by calculating a weighted average allowable mass emission and a weighted average actual mass emission each month using heat inputs or steam production for each unit.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcatgories. The final rule retained the common stack provisions to allow units from different subcategories that share a common stack to comply using a separate Equation 6. See response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 205 for discussion of the legal case Chevron U.S.A., Inc. v. NRDC.

Comment: Averaging across subcategories should be permitted for dioxins/furans and carbon monoxide. A source should be allowed to comply with the dioxin/furan (D/F) standard via emission averaging. While it may not be appropriate to set numerical emission standards for D/F, if the final rule does include such numerical standards, a source with multiple units could choose to comply by installing a post-combustion control (such as powder activated carbon injection) to reduce D/Fs on some units at a facility.

Additionally, carbon monoxide should be included in the emissions averaging provision, since some units may be able to easily meet the proposed CO limits, while, for others, it may impossible. To facilitate its inclusion, the emission limitation for CO should be expressed in an alternative form – lb/mmBtu. For the case of units using CEMS to measure CO, precedent exists for this as well, in the emission averaging provision for NOx found at 40 CFR 76.11. Heat input should be allowed to be determined using either flow monitors (some units subject to the NOx budget trading program have these already) or using fuel factors and diluent monitors per 40 CFR 60 Method 19.

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging and response to EPA-HQ-OAR-2002-0058-2702.1, excerpt 206 for alternative units of measure for CO.

Comment: EPA imposes a restriction on emissions averaging that requires facilities using that option to meet a standard that is 10% stricter than the otherwise applicable limits. 75 Fed.Reg. at 32,035. EPA should remove this 10% penalty for using emissions averaging because it is arbitrary, unnecessary for environmental protection and reduces the flexibility that averaging provides. EPA asserts that its inclusion further ensures the allowable emissions are at least as stringent as the MACT floor limits without using averaging. However, EPA offers no demonstration of this in the proposal. Given the accuracy of heat input weighted emission calculations, there is no uncertainty that the average emission rates would be any less stringent than when not using averaging.

Because EPA has already determined that the standards in the rule achieve the maximum emission reduction achievable for health and environmental protection, to require an additional 10% reduction of emissions has no basis in the environmental underpinnings of the rule. Because emissions averaging is a compliance alternative, the 10% discount factor constitutes a beyond-the-floor requirement that EPA has not analyzed for its cost, non air quality and energy impacts, as required by CAA §112(d)(2). Finally, although the 10% discount may be perceived as a fair trade-off for the flexibility of emissions averaging, it still lacks a legal basis and creates a disincentive for sources to use this compliance method. Because the proposed limits in this rule are so tight, sources would not be able to ensure an additional 10% reduction in emissions below the limits and imposing this requirement effectively deprives many sources of the availability of the emissions averaging compliance alternative.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: Emissions Averaging is Appropriate but Should Not be Penalized

AISI supports EPA's use of emissions averaging as a flexible compliance alternative for facilities with multiple units. The Proposed Rule was correct to recognize emissions averaging as an "equivalent, more flexible, and less costly alternative to controlling certain emission points to MACT levels." Id. at 32034. That cost savings and additional flexibility comes at no environmental or health risk since overall emissions will fully comply with the promulgated MACT standards. However, AISI does not support the proposal to apply a "discount factor of ten percent" when emissions averaging is used to "further ensure that averaging will be at least as stringent as the MACT floor limits in the absence of averaging." 75 FR at 32035. This penalty erodes the very compliance flexibility that emissions averaging is designed to create without explaining why any penalty is necessary to uphold the stringency of the MACT floor.

The emissions averaging provisions in the 2004 Boiler MACT Rule were substantially similar to those in the current Proposed Rule. Both allowed sources to demonstrate compliance with certain emissions limits by averaging the emissions from one or more existing sources at the same facility that are in the same subcategory. Compare 75 FR at 32053, with 69 FR at 55257. Both required sources utilizing emissions averaging to take the following steps to ensure that implementation for these units would be no less stringent than unit-by-unit implementation: (1) demonstrate that the emission rate achieved during the compliance test does not exceed the emission rate that was being achieved at a set time after publication of the final rule, (2) demonstrate that the control equipment used during the compliance test is no less effective than it was at the same set time, and (3) develop and submit an emissions averaging implementation plan for approval. Compare 75 FR at 32053, with 69 FR at 55258-59.

EPA defended its inclusion of the emissions averaging compliance alternative in the 2004 Boiler MACT Rule as follows:

EPA has concluded that it is permissible to establish within a NESHAP a unified compliance regimen that permits averaging across affected units subject to the standard under certain conditions. Averaging across affected units is permitted only if it can be demonstrated that the total quantity of any particular HAP that may be emitted by that portion of a contiguous major source that is subject to the NESHAP will not be greater under the averaging mechanism than it would be if each individual affected unit complied separately with the applicable standard. Under this rigorous test, the practical outcome of averaging is equivalent in every respect to compliance by the discrete units, and the statutory policy embodied in the MACT floor provisions is, therefore, fully effectuated.[Memorandum from Jim Eddinger, ESD Combustion Group, to Robert Wayland, ESD Combustion Group, re: Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP (Feb. 25, 2004) (EPA-HQ-OAR-2002-0058-0611).]

The 2004 Boiler MACT Rule did not contain any penalty provisions for emissions averaging, concluding that the safeguards enumerated above were sufficient. EPA has offered no explanation for why these steps are insufficient in 2010, or why a penalty of 10% is necessary to uphold the MACT floor for all sources. Nor did the intervening D.C. Circuit court decision offer any input on this topic. EPA is required to provide a “reasoned explanation ... for disregarding facts and circumstances that underlay ... prior policy.” FCC v. Fox Television Stations, Inc., 129 S. Ct. at 1810. EPA’s decision to include a penalty provision in the Proposed Rule, given its prior defense of emissions averaging absent such a provision, is arbitrary and capricious.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 89

Comment: We agree that incorporating emissions averaging into the emission standards is a proper way to encourage flexibility and cost savings for affected facilities. There is ample precedent in the MACT program for allowing "bubbling" or emissions averaging. For example, the Pulp and Paper Chemical Recovery Combustion rule allows plants to set a PM emissions limit for each existing applicable process unit such that, if these limits are met, the total emissions from all existing process units are less than or equal to a "bubble" limit on all affected units. [See 66 Fed. Reg. 3180, 3184 (January 13, 2001) and 40 C.F.R. Part 63, Subpart MM. See also 67 Fed. Reg. 78046 (December 20, 2002) (proposing bubbling in the Lime Manufacturing rule).] Many other MACT standards have included emissions averaging provisions. See, e.g., 40 C.F.R. Part 63, Subpart JJJ (Group IV Polymers and Resins); 40 C.F.R. Part 63, Subpart U (Group I Polymers and Resins); 40 C.F.R. Part 63, Subpart G (Synthetic Organic Chemical Manufacturing Industry: Process Vents, Storage Vessels, Transfer Operations and Wastewater); 40 C.F.R. Part 63, Subpart LL (Primary Aluminum Reduction Plants); 40 C.F.R. Part 63, Subpart CC (Petroleum Refineries); 40 C.F.R. Part 63, Subpart EEE (Hazardous Waste Combustors).]

Under a bubble approach, each unit is assigned an enforceable permit limit and all permit limits, in the aggregate, must meet the standard. In contrast, in an emission averaging approach the source calculates its baseline emissions from regulated units, determines the net reductions that are required, and ensures that those emissions reductions are achieved through a combination of controls at regulated and unregulated sources. As such, greater recordkeeping and reporting requirements are associated with an emissions averaging plan, as compared to a bubble approach.

Bubbling and emissions averaging are well demonstrated techniques for meeting or exceeding environmental objectives at lower cost and with greater flexibility tailored to individual affected facilities. Provisions such as these allow plants to optimize their investments by installing controls on units where the lowest emission rates can be achieved in the most cost-effective manner possible. For example, a source could decide to over-control a newer unit in order to avoid costly investments in an older unit that may be retired before the useful life of the control device is reached. Bubbling provisions also provide environmental benefit by allowing for control options that minimize energy use. Energy efficient decisions benefit the environment by reducing power demands and the secondary pollutant impacts they generate.

Response: EPA acknowledges support of the emission averaging provision and has retained the emission averaging provision in the final rule.

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 90

Comment: ACC concurs with EPA’s proposal and past precedent that use of the emissions averaging compliance alternative should be limited to existing units. New and reconstructed boilers/process heaters should be required to meet the more stringent "new source" requirements.

Response: We acknowledge the support and prior precedent. The final rule has retained the limitation of emission averaging provisions to existing sources.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 91

Comment: However, we believe that additional flexibility should be incorporated into the proposed emissions averaging provisions in this rule in order to ensure facilities have options to reduce the cost of compliance. The emissions averaging or bubble provision should be based on actual operating time and emissions and not capacity. Adding the element of time ensures equivalent control regardless of boiler operating schedules and provides flexibility with respect to the control strategy for limited use boilers. Some boilers are only used during maintenance outages, and incorporating flexibility into the emissions averaging provisions to accommodate limited use boilers will greatly reduce the compliance cost for these boilers. Boilers sharing common stacks should also be eligible for inclusion in the emissions averaging approach, especially if emissions can be measured from each boiler prior to the common stack. EPA has included all common stack units in its floor analyses by applying the measured common emission rate to each unit, instead of one time for the group of units, so this approach could also be used in an emissions averaging compliance scenario.

In addition, ACC believes that boilers of any design firing any fuel, and in any subcategory, should be included in the bubble and that facilities should not be limited to use of emissions averaging for boilers only in the same subcategory. There is no justification for restricting emissions averaging only to boilers in a specific subcategory; facilities should be able to average emissions from stoker boilers with emissions from pulverized coal boilers and liquid boilers. This approach has been used in several of the rules mentioned above. For example, the Pulp and Paper Chemical Recovery Combustion rule and the HON allow emissions averaging across different types of units. The equivalency by permit provisions in 40 CFR 63.94 allow sources to "trade" emissions from unregulated sources for emissions of regulated sources, so this is additional reason not to restrict use of emissions averaging to boilers within the same subcategory.

Response: See response to comment EPA-HQ-OAR-2002-0058-2694.1, excerpt 3, for response to actual vs. rated heat input capacity and a discussion of how units with common stacks can participate in the emissions averaging provision.
See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 175 for emission averaging between subcategories.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 92

Comment: ACC disagrees that a 10% penalty for use of emissions averaging is appropriate. This requirement restricts the utility of the proposed emissions averaging provisions, especially as this demonstration is proposed to be based on unit capacity and not actual unit operating data. The Pulp and Paper Chemical Recovery Combustion rule allows bubbling of emissions with no requirement to further reduce emissions to 90% of the allowable emission rate.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Commenter Name: Jim Griffin

Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 93

Comment: ACC believes that the application of the underlying principles of emissions averaging, as stated in this proposed rule, is sufficient to fully realize the statutory requirements that affected sources meet the standards, and that no discount factor is required. Moreover, EPA fails to justify the necessity to further tighten emissions standards when averaging is used. This point is further reinforced by the fact that EPA expressly excluded the provisions of emissions averaging, including the discount factor, to a situation where individual units are vented through a common stack. EPA must realize that there is no difference in actual emissions between two units emitting from separate stacks and the same units, operated in an identical fashion, emitting from a common stack. The quantity of contaminants emitted to the atmosphere will be identical in both circumstances and imposing a discount factor to the units emitting separately will discourage many facilities from using this compliance option.

EPA bases its justification for a discount factor on the emissions averaging provisions in this rule on the HON, stating that the legal basis and rationale for the HON emissions averaging provisions have been provided in the preamble to the final HON. [59 Fed. Reg. 19425 (April 22, 1994).] However, EPA dismisses this discount provision in the preamble to the proposed NESHAP rule for Plywood and Composite Wood Products (PCWP rule), stating:

...(the) HON sources have many emission points, are complex and diverse, and as a result are subject to a more complex set of emissions averaging provisions. The PCWP facilities have fewer emission points within each facility. Therefore, the enforcement concerns arising due to the large number of emission points in each HON facility are minimized for PCWP facilities." [68 Fed. Reg. 1290 (January 9, 2003).] EPA concludes its argument to dismissing a discount factor for PCWP sources by stating that "...(the) HON requires a discount factor of 10 percent in credit calculations to share with the environment some portion of the cost savings due to emissions averaging and to account for uncertainty in emissions estimation. Due to differences between PCWP and HON sources (discussed below), we do not believe it is necessary for the proposed PCWP rule to include a discount factor.[68 Fed. Reg. 1290 (January 9, 2003).]

This conclusion was maintained in the final version of the PCWP rule. [69 Fed. Reg. 45973 (July 20, 2004).] In fact, the concept of imposing a discount factor on the use of emissions averaging was never discussed neither in the initially proposed [68 Fed. Reg. 1660 (January 13, 2003).] nor the 2004125 Boiler rule. Thus, imposing a discount factor to the emissions averaging compliance alternative is unwarranted and unjustified.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Comment: ACC recommends that sources be given the flexibility to use emissions averaging provisions or include alternative bubble emission limits for dioxin as well as for PM/TSM, HCl, and mercury. For dioxin, which is a concentration based limit and not a mass based limit, the source would calculate its recommended alternative bubble limits using an approach similar to that included in the Pulp and Paper Chemical Recovery Combustion rule for the PM limits in gr/dscf, and these bubble limits would be submitted to the permitting authority for approval and inclusion in the air permit. The alternative bubble limits would be set during the initial compliance test. Separate alternative bubbling calculations could be submitted for PM, total metals, mercury and/or HCl at the discretion of the applicant. A bubbling plan need not include all pollutants; and for any pollutants not specifically included in the bubbling plan, the applicable rule's emissions limitations would apply as a default.

An equation on page 65 of the submittal could be used to define this averaging methodology:

Where:

Ave Weighted Emissions = Average weighted emissions for Dioxins/Furans, in concentration units (ng/dscm (TEQ) corrected to 7 percent oxygen);

Ec = Emissions rate, as calculated expressed in ng/dscm (TEQ) corrected to 7 percent oxygen;

Fg = Stack volumetric flow rate

Response: See response to comment EPA-HQ-OAR-2002-0058-2801.1, excerpt 36 for discussion of pollutants eligible for emissions averaging and EPA-HQ-OAR-2002-0058-2694.1, excerpt 6 for response to comments establishing site-specific alternative dioxin limits.

Comment Excerpt Number: 95

Comment: The proposed rule contains a requirement for the facility to demonstrate each month that the average weighted emissions of the boilers included in the emissions averaging scheme are below the applicable emission limit using the actual heat inputs for that month. ACC believes that an annual determination that the emissions averaging or bubble limits are being met is more than satisfactory to ensure protection of public health and welfare and appropriate for consideration for a technology-based MACT standard.

Response: See response to EPA-HQ-OAR-2002-0058-3213.1, excerpt 180 for response to comment on monthly compliance determinations.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 96

Comment: The first compliance demonstration should not be required immediately after the rule compliance date, as maintenance and outage schedules may make it hard for a facility to comply with the emissions averaging provisions without 12 full months of data. Other rules do not require a monthly test (e.g., the HON), but provide a 30 percent allowance during each quarter and equivalency on an annual basis. Although a year is an appropriate period for determining the time-weighted average emissions rate, consideration may be given for convenience sake to a shorter 6 month period that coincides with the required reporting period for the standard. It is expected that a 6 to 12 month period would provide the flexibility needed to retain the benefit of the recommended averaging or bubbling provisions. [69 Fed. Reg. 55218 (September 13, 2004).]

Response: See response to EPA-HQ-OAR-2002-0058-2824.1, excerpt 23 for response to comment on timing of first compliance demonstration.

Comment: EPA Should Fix Errors in the Discounting Formulas for Emissions Averaging

For the Major Source Rule, EPA is proposing to allow emissions averaging within a regulated source over its existing individual boilers in the same category. This is being proposed as a flexibility mechanism because emissions reductions may be cheaper at a particular unit. This proposal is subject to several conditions including an "emissions averaging plan" and a cap on the overall emissions level. [Footnote: 75 Fed. Reg. at 32,034-35.] In addition to these other safeguards, EPA is proposing a discount factor of ten percent to "ensure that averaging will be at least as stringent." [Footnote: 75 Fed. Reg. at 32,035] The agency is requesting comment on "use of a discount factor and whether ten percent is the appropriate discount factor." [Footnote: 75 Fed. Reg. at 32,035]

While the practical effect of this is not clear from the preamble, it is possible to discern its impact from the proposed regulatory language. Section 63.7522(d) of the proposed rule states that the "The averaged emissions rate from the existing boilers and process heaters participating in the emissions averaging option must be in compliance with the limits in Table 2 [emissions limits for existing sources] to this subpart at all times following the compliance date. . . ." [Footnote: 75 Fed. Reg. at 32,053]

Section 63.7522(e) then gives two alternative formulas to demonstrate initial compliance. According to these formulas, the average emissions rate used to determine compliance is only 90% of the actual weighted average emissions rate (in this case, weighted by the maximum rated heat input capacity). Subsequent to this, each entity must demonstrate compliance on a monthly basis according the formulas laid out in Section 63.7522(f). [Footnote: 75 Fed. Reg. at 32,053-54] Similarly to the formulas for initial compliance, the average emissions rate here is also only 90% of the actual weighted average emissions rate (weighted here by actual heat input).

These formulas appear to be mistaken and, instead of multiplying by 0.9, they should be multiplying by 1.1 (or dividing by 0.9). To see the error in the formulas, the simplest case can be considered. If there are two boilers at the same facility with identical heat input capacity and actual monthly heat input, then instead of a weighted average the formulas reduce to a simple average. Thus, if both actual emission rates for a given pollutant are 1, then the simple average emission rate is 1. This figure is then multiplied by 90%, giving an emissions rate of 0.9 for the purposes of regulatory compliance. Obviously, the result of the formula is a lower emissions rate than the actual correct weighted average. This seems directly contrary to the stated purpose of the discounting provision and should be fixed by EPA.

If the formulas are corrected to be in accord with the stated purpose of the discounting provision, there will be several effects from discounting. By penalizing averaging, it disincentivizes sources from using this option. This will lead to fewer cost savings, which is the goal of allowing averaging in the first place. However, averaging may lead to fewer reductions in emissions and thus fewer benefits to the general public. The net effect of this is ultimately an empirical one. If the agency is under-regulating (as seems likely, see supra pp. 8-9), then the decrease in emissions reductions is unwarranted and not worth the reduced costs. However, if the standards are set efficiently (as we argue they should be), this should be unnecessary unless it is motivated by other concerns (such as measurement error).

EPA should have an independent justification for any discounting provision that explains why it should be implemented and not just what its effects are. It is impossible to determine what the proper discount factor should be without knowing the provision’s purpose. The justification of ensuring stringency could equally well justify a discount factor of 5%, 10%, or 20%.

Response: See response to EPA-HQ-OAR-2002-0058-2808.1, excerpt 30 for the discount factor.

Switching Subcategories

Commenter Name: Michael G. Dowd
Commenter Affiliation: Virginia Department of Environmental Quality, Air Division
Document Control Number: EPA-HQ-OAR-2002-0058-2631.1
Comment Excerpt Number: 3

Comment: VADEQ would like EPA to provide implementation guidance for establishing the boiler's initial fuel subcategory as well as procedures for various fuel switching scenarios so that state and local programs will be equipped to implement the rule when promulgated. In particular, VADEQ seeks EPA implementation guidance on the following issues:

* In the proposed rule, the boiler's fuel subcategory is based on the boiler type and percentages of fuel used on an annual average heat input basis. For existing boilers, what initial time period should a facility use to determine what fuel emission standards must be met? VADEQ recommends the 12 month period prior to the compliance date for determining the boiler's fuel subcategory.
* Will facilities be able to switch fuels and become subject to a different standard? If so, when would the facility become subject to the new standard and when would they need to show compliance? VADEQ supports facilities being able to switch fuel and become subject to a different standard. VADEQ suggests that when the fuel burned in the boiler meets the definition of the new fuel category based on the rolling annual average heat input basis, the boiler should then be subject to the new standards and compliance demonstrated within 180 days.
* Can boilers go back and forth between fuel subcategories or does, "once in, always in" apply? VADEQ supports allowing fuel switches as long as the process for doing so is clear.
* Can a boiler go from a fuel subcategory with emission limits to a subcategory without emission limits, for example switching from distillate oil to only natural gas?

Response: The definitions for the liquid and gas fuel subcategories refer to a percentage heat input for a given type of fuel determined on an annual average. EPA agress that the relevant subcategory should be based on the 12 months immediately preceding the compliance date for existing sources. EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch. A facility would become subject to the new standard on the effective date of the fuel switch and they must provide 30 days notice before switching fuels, if that fuel switch will result in a change in subcategory. Boilers will be allowed to go back and forth between fuel subcategories, but must do so in a way that does not compromise their or our ability to assess the continuing compliance status of the facility. As such sources must not switch fuel subcategories more frequently than once every 30 days after the initial test that demonstrates compliance.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 24

Comment: In order to stay in business and/or minimize costs, many boilers and process heaters will opt to change fuels to Gas 1 prior to the compliance date of this regulation. In that case, the past year‘s fuel would not be the appropriate basis for a unit‘s initial subcategory assignment.

Recommendation: Where a source commits to meet the Gas 1 source category definition before the rule compliance date for a particular boiler or process heater, provision should be provided to assign that boiler or process heater to the Gas 1 subcategory until one calendar year of fuel use data after the compliance date is available.

Response: The definitions for the liquid and gas fuel subcategories refer to a percentage heat input for a given type of fuel determined on an annual average. The 12 months immediately preceding the compliance date for existing sources would be used to determine the annual heat input and the applicable subcategory. However, the commenter raises an important point. If the source intends to switch fuels within the 12 months immediately preceding the compliance date, consistent with the intent of the provisions that EPA has added to the regulations that allow for a switch in subcategories as a result of a fuel switch, the source may switch fuels up until just before the compliance date, if the source provides advance notification of their intent to switch fuels, consistent with the notification provisions added to the final rule.

Comment Excerpt Number: 30

Comment: What are the ramifications if we plan to fire less than 10% oil in a boiler but then go over this amount? Can the compliance approach vary from year to year – one year gas, one year oil? Our fuel selection is based on a variety of factors including price, maintenance requirements, and the need to turnover the oil tank contents routinely. We recommend that if a boiler has the intent of meeting the definition of a gas 1 subcategory but exceeds the oil usage restriction as documented during a semiannual report, that during the subsequent 6 month period a compliance demonstration be completed (either through stack testing or fuel analysis) such that the next semiannual report documents compliance with the liquid subcategory emission standards.

Response: Once the applicability to a given subcategory is determined, the source must remain in compliance with all the terms of that subcategory including the defined type and amount of fuel that is to be combusted for that subcategory, and all the associated emission limitations and associated monitoring, recordkeeping and reporting requirements for the subcategory. However, EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch. Upon switching subcategories, the new subcategory definitions would apply to the source.

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 53

Comment: As we pointed out previously, there are also a great many practical and regulatory issues associated with having two gas subcategories. Individual boilers and process heaters can move, often for unplanned reasons, between the gas subcategories. Revising the definitions of the subcategories as recommended previously will help limit these occurrences, but will not eliminate them. A Gas 1 operation may shift to a Gas 2 operation because of construction of a new process unit that generates gas, thereby backing out natural gas from some combustion sources, or a Gas 2 unit may become a Gas 1 unit because a gas producing unit is shut down. Even with the Gas 1 and 2 definition changes we recommend, it is not out of the question that more than 10% of the firing in a calendar year of a particular unit will be from the Gas 2 category, just due to operating variability as streams are mixed. Every time a gas-fired unit changes subcategory, there will be permitting and compliance issues and, in transitioning from the Gas 1 to the Gas 2 requirements, major investments.

Response: The 12 months immediately preceding the compliance date for existing sources would be used to determine the annual heat input and the applicable subcategory. EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch.

Commenter Name: Michael Potter

Document Control Number: EPA-HQ-OAR-2002-0058-3181
Comment Excerpt Number: 2

Comment: Goodyear has boilers with capability to fire either natural gas or fuel oil. These boilers could be included in either the Gas 1 subcategory or the liquid fuel subcategory depending on the portion of annual heat input provided by the liquid fuel. Historically this proportion has varied significantly from year to year, and from plant to plant.

Response: The definitions for the liquid and gas fuel subcategories refer to a percentage heat input for a given type of fuel determined according to the relative annual heat input of each fuel type. The 12 months immediately preceding the compliance date for existing sources would be used to determine the annual heat input and the applicable subcategory. EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch.

Commenter Name: Gordon M. Smith
Commenter Affiliation: Mitsubishi Polyester Film, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2912
Comment Excerpt Number: 5

Comment: The subcategories of boilers and process heaters to which the proposed rule applies are listed in §63.7499. Gas- and liquid-fired boilers and process heaters can often change fuels with little or no equipment modification. For instance, units with both liquid and gas capability can move from gas to liquid with simple fuel realignments.

The movement of a unit from a gas subcategory to the oil subcategory and vice versa must be addressed. This can happen because of changes in fuel economics or due to fuel delivery interruptions. In this case we also request three years be allowed for the unit to re-permit and to comply with the new set of requirements.

Response: The definitions for the liquid and gas fuel subcategories refer to a percentage heat input for a given type of fuel determined on an annual average. The 12 months immediately preceding the compliance date for existing sources would be used to determine the annual heat input and the applicable subcategory. EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch. There are no compliance extensions available beyond the specific extension allowed for in Section 112(i). EPA has already provided the three year extension in setting the initial compliance date for this rule. Source may request an additional year extension and these requests will be considered on an case-by-case basis.

Commenter Name: John Steber
Commenter Affiliation: Performance Fibers
Document Control Number: EPA-HQ-OAR-2002-0058-3174
Comment Excerpt Number: 7

Comment: Should heat input be based on a rolling 12-month average rather than an annual average — PFI believes that the use of a 12-month rolling average would allow facilities (and regulators) to monitor and assess its subcategory status more easily throughout the year and provide a better indicator than an end-of-year type of evaluation.

Response: EPA agrees that the heat input should be based on a 12 month average instead of a calendar year annual basis. A source attempting to establish which subcategory applies using the heat input criteria would base its determination on the immediately preceding 12 months of operation. The 12 month period immediately preceding the compliance date of the standard would be used to determine the appropriate subcategory for the unit. EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch.

Commenter Name: Daniel Moss
Commenter Affiliation: Society of Chemical Manufacturers and Affiliates
Document Control Number: EPA-HQ-OAR-2002-0058-2926.1
Comment Excerpt Number: 7

Comment: EPA should also clarify over what annual averaging period the 90% heat input basis calculation should be performed: Rolling 12 months? Calendar year? Last 5 years? Last 10?

SOCMA recommends that EPA specify a five-year annual averaging period, so that facilities' calculations align with other determinations that they make for Title V permitting purposes.

Response: The annual heat input basis used in the subcategory definitions is based on an annual average for the immediately preceding 12 month period. A source attempting to establish which subcategory applies would base its determination on the immediately preceding 12 months of operation. The 12 month period immediately preceding the compliance date of the standard would be used to determine the appropriate subcategory for the unit. EPA is adding provisions to the regulations that discuss how to switch subcategories as a result of a fuel switch.

Comment: Emission limits should apply only when burning the fuel for which the limit was developed.

The definition of liquid fuel subcategory clearly acknowledges that the boiler owner/operator may burn fuel other than a liquid fuel in a liquid fuel subcategory boiler. In the case of a natural gas fired boiler that may also use fuel oil to provide more than 10 percent of the annual heat input, the boiler would need to be equipped with control equipment adequate to achieve the liquid fuel subcategory emission limits in Table 2 when burning oil. However, the control equipment is not only expensive to purchase and install, but is also expensive to operate, and controls should not be required to operate when only natural gas is being used. For example, the liquid fuel category standard limits carbon monoxide (CO) emissions to 1 ppm adjusted to 3 percent oxygen. However, there is no CO limit or any other numerical emission limit applicable to boilers that only burn natural gas. In order for the liquid fuel subcategory boiler to achieve the 1 ppm limit when burning only natural gas, the excess air used in the boiler would need to be unusually high leading to lower boiler efficiency. The lower boiler efficiency, in turn would require use of more natural gas. This is clearly at odds with the proposed requirements in Table 3 regarding conducting an energy assessment.

Additionally, add-on control equipment uses extra energy to operate. Unnecessary usage of the add-on control equipment wastes energy, contrary to the intent of the energy assessment requirement. Further, the CO limit is not a reasonable limit when burning natural gas because the CO limit is a surrogate for organic HAP emissions from fuel oil that are not likely to occur when burning natural gas.

Based on the foregoing, Goodyear believes the proposed regulations should be revised to specify that the emission limits will apply only when burning the fuel for which the limits were developed, or at least to specify that no numerical emission limits should apply when burning only Gas 1 fuels regardless of the subcategory that applies to the boiler.

Response: EPA disagrees with the commenter. The emission limits apply to each subcategory and the subcategories are based on an annual basis. Gas 1 units that fire liquid under the limited circumstances allowed for curtailment and periodic testing are still considered gas 1 units and are not subject to emission limits while firing liquid. We have added provisions to the final rule to allow units to switch subcategories based on the immediately preceding 12 months of operation.

Comment: The proposed standards should allow a boiler to undergo a change in applicable subcategory with adequate time allowed to install necessary control equipment.

Proposed 40 CFR section 63.7495(c)(2) specifies that existing boilers at HAP area sources that become HAP major sources must comply with the requirements within three (3) years after the source becomes a major source. Goodyear believes there may be situations where existing boilers with both gas and oil firing capability that intend to limit themselves to less than 10 percent oil firing may later find it necessary to opt into the liquid fuel subcategory. Consequently, Goodyear believes that 40 CFR section 63.7495 should be revised to provide such a boiler adequate time to install needed controls.

Response: The rule has been amended to clarify that sources may move between subcategories. EPA is providing sources the flexibility to choose the effective date for a fuel switch, and is allowing for an unlimited number of fuel switches . Procedures have been developed to provide this flexibility while not compromising our ability to determine compliance with the standards. The procedures allow facilities to build as much time into coming into compliance with the new subcategory as sources deem necessary. However, sources must remain in compliance with their currently applicable subcategory at all times, are expected to be in compliance with the new subcategory on the date identified in the notification, and are not allowed to operate out of compliance with the currently applicable subcategory while they install controls. After expiration of the initial compliance deadlines in 63.7495, sources are expected to be in continuous compliance with an applicable boiler MACT subcategory. There are no provisions for extensions of compliance beyond the three years already provided in the regulation and the case by case extensions for installation of controls. Consistent with 63.6(i)(4)(i)(B), requests for a one year extension for installation of controls must be submitted no later than 120 days prior to the affected source's compliance date.

Commenter Name: American Crystal Sugar Company and Michigan Sugar Company
Commenter Affiliation: Patricia Hansen and Steven Smock
Document Control Number: EPA-HQ-OAR-2002-0058-2970.1
Comment Excerpt Number: 20

Comment: The agency needs to clarify the subcategory classification. For a boiler with an unchanging or small changes in the fuel fired, the definitions of the subcategories are straight forward. However some boilers do have significant changes in the fuel utilized in a given year or more. For example, some boilers can fire liquid or natural gas (or several other combinations). Depending on the market it may fire 100% natural gas or 100% liquid fuel or some mix of the two in a given year. It is clear that in any year that the boiler's heat input exceeds 10% from a liquid fuel the boiler is a liquid fuel boiler for that year. However; how is the boiler classified during the year(s) if it fires only natural gas? Additionally, would this classification be affected if the boiler's operational period does not match the calendar year? For the Sugar Beet industry the operational year (and generally fiscal year) is from early fall to late spring. The range of operation is from —90 to —260 days.

Response: A source needs to identify, in the Notification of Compliance Status under 63.9(h)(2)(ii) and 63.7545(e)(1), the subcategory the source is in. The subcategory classification is based on the 12 month period immediately preceding the compliance date of the standard. However, sources with dual firing capability may pick which subcategory they intend to comply with, and must continue to comply with the provisions in that subcategory until such time as they become subject to a new subcategory, consistent with the procedures for fuel switches which have been added to the rule. The source would notify the Agency of its intended subcategory in the initial notification required in 63.9(b)(2). If the source intends to switch subcategories prior to the initial compliance date, it must provide advance notification, consistent with the procedures added to the regulation. The rule has been amended to clarify that sources may move between subcategories consistent with the procedures promulgated.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 222

Comment: EPA should propose for comment how and when units would move between subcategories in the rule based on the actual fuel mix fired and how and when compliance would be demonstrated for a different subcategory than the one the unit was under for the initial compliance demonstration.

Response: The rule has been amended to clarify that sources may move between subcategories and has promulgated procedures that provide flexibility to sources while not compromising their and our ability to determine continuing compliance with the standards. The procedures specify compliance and testing obligations.

Common Stack Provision

Commenter Name: Steven M. Maruszewski
Commenter Affiliation: The Pennsylvania State University
Document Control Number: EPA-HQ-OAR-2002-0058-2729.1
Comment Excerpt Number: 13

Comment: Common Stack - Start-up / Shut down
Penn State understands that the applicable sections of 40 CFR 63 were vacated and that 24 hour and 30 day averaging is included in the draft regulation. The University's concern is that during the start of our heating season, we will likely bring on all four boilers at the West Campus Steam Plant sequentially over a short period of time. All four boilers are ducted to a single stack. The CO monitor installed in that single stack will measure significant startup levels of CO during a comparatively short time span. The reverse of this process will happen at the end of the heating season. The University is requesting that there be an accommodation for such process when multiple sources are ducted to a common stack. [Attachments 3b and 3c in the submittal clearly show this relationship.]

Response: EPA has provided a work practice during periods of start up and shutdown in the final rule. See the preamble for a final discussion of startup and shutdown.

Comment: It is not uncommon for boilers or process heaters to share a common stack or to be located very close together. The proposal recognizes the common stack situation and addresses monitor configurations for such situations. One efficiency item that is not addressed is the potential sharing of analyzers and we request that be added in the final rule. CO and O2 CEMS are rapid response instruments and thus can sometimes be shared, particularly where multiple sources share a common stack, while easily meeting the requirement for obtaining data at least every 15 minutes.

Recommendation: Allow sharing of CEMS as long as the data frequency and other CEMS requirements are met.

Response: It is possible that sample conditioning systems and analyzers can be shared where multiple sources share a common stack, provided the common stack, data frequency and other CEMS requirements are met. Sources should describe how they will meet the monitoring requirements in the site-specific monitoring plan developed for this rule as specified in §

63.7505(d) and 63.8(e). It is noted that CO CEMS requirements have been removed from the final rule.

Comment: Our Luke Mill operates three boilers, two of which are coal fired and the third unit is a natural gas unit. All three boilers discharge into a common stack. The common stack requirements contained in § 63.7522 are of interest to us but we have some concerns with the proposal.

We believe that boilers of any design firing any fuel (e.g., in any subcategory) that vent through a common stack need to be included in the common stack provision. We do not believe there is any justification for restricting the common stack emission averaging provisions only to boilers in a specific subcategory; facilities need to be able to average emissions from all types of boilers that vent to a common stack. In addition, the performance test needs to be completed when all units are venting to the common stack as they usually do. The shutting down of a boiler/unit or venting to another stack in order to complete a performance test could cause significant operational issues for a facility.

Response: The provisions of 63.7522(j), which are part of the common stack provisions, allow for emissions averaging between different subcategories. Emissions from a nonaffected unit cannot be included in the compliance determination for the MACT rule. As such, the rule requires at 63.7533(j)(2) that if nonaffected units vent to the common stack, the nonaffected units must be shut down or vented to a different stack during the performance test. EPA notes, however, there is a typo in that provision which states, "If affected units from nonaffected units vent to the common stack..." when it should read, "If affected and nonaffected units vent to the common stack..." EPA has made this correction. Emissions avergaing is only a compliance option, so if shutting down nonaffected units creates significant operational problems for the facility, and if the facility cannnot or will not vent those emissions to another stack, then emissions averaging may not be a preferable option for the facility.

Commenter Name: David Bonistall
Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 36

Comment: We believe units venting to a common stack need to be allowed to average emissions for all Boiler MACT pollutants. The proposed rule language is not clear if the common stack requirements allow emission averaging for all of the Boiler MACT pollutants. Units that vent to a common stack should not be limited to just averaging particulate matter, HC1 and mercury.

Site-specific situations may not allow for satisfactory monitoring locations in the ducting or breaching prior to reaching the common stack.

Response: EPA has developed several compliance flexibilities in this rule, and treatment of common stacks and the emissions averaging provision are two of such compliance flexibilities. Facilities whose sources vent to a common stack and want to use the emissions averaging provision are also subject to the discount factor. Facilities that opt to comply with the provisions set forth for common stacks without using emissions averaging are not subject to a discount factor. The requirements and language of the common stack option are a result of an earlier focused Agency reconsideration and the resulting public comments received on that reconsideration (See 71 FR 70651). The common stack introduces testing flexibility since testing emissions from a common stack for a group of boilers would be equivalent to the average emissions calculated from individual stack tests on each unit contributing to the stack emissions. Testing once per stack reduces the testing costs associated with boilers venting to the same stack. The scope of applicable sources is very narrow since not all units at a facility vent to a common stack. The emissions averaging option introduces a broader compliance flexibility, and since some units may opt to over control some sources while undercontrolling other sources in order to stategically allocate capital for control devices. EPA determined that given prior precedence for a discount factor in emissions averaging situations, and the broader impact emission averaging has on similar units across a facility, that a discount factor remains appropriate. Further, in many cases EPA notes that more than one of these compliance flexibilities is available to regulated entities.

Comment: The proposed emissions averaging procedures do not apply when unaffected units or units in different subcategories are ducted to a common stack. As EPA states in the Preamble, these units are excluded because it is not possible to distinguish the emissions from each individual unit.

This issue was addressed in EPA's reconsideration of the emissions averaging provisions under the vacated Rule. In the vacated Rule, EPA permitted such units to be included in the averaging plan with the requirement that emissions from the affected units in other subcategories or non-affected units be shut off or vented to a different stack during testing. This clearly allows emissions to be quantified from all units in the emissions averaging group, and, therefore, should be allowed under the current IB MACT Rule as well. Likewise, the same requirements should be included for common stack units that are not included in an averaging plan.

Response: The common stack provisions in the emissions averaging procedures do allow for averaging among affected units even if there are unaffected units that can vent to the common

stack, if the emissions from the non-affected units are shut down or vented to a different stack during the performance test. See 63.7522(j)(1)&(2).
Affected units that share a common stack do not have to take part in emissions averaging. If units that are subject to different subcategories are able to monitor compliance separately, we encourage them to do so. The test plan and site-specific monitoring plans required to be submitted under 63.7(c) and 63.7505(d) need to address how these units will conduct the performance tests and monitor.

Comment: Within the emissions averaging options at §63.7522(h), EPA has defined certain compliance alternatives for a common stack configuration – where more than one boiler shares a common stack. EPA has properly stated the requirements in §63.7522(i) for two or more boilers in the same subcategory, each of which vents through a common control device to a common stack. However, EPA's language in §63.7522(j) appears to be intended, but is not crystal clear, for another common configuration – where there are two or more boilers in the same subcategory, each of which vents through its own control device to a common stack.
GP's Muskogee Mill Configuration
GP's tissue mill at Muskogee, OK has two coal-fired boilers, each with its own baghouse that vents to a common stack (Stack 3) that has a common opacity monitor.
(See submittal for a sketch a these boilers)
Any stack testing on these boilers must be done in the common stack – testing in the ductwork from the baghouses to the common stack would not meet the required upstream and downstream distances for test ports in EPA testing methods.

40 CFR 63.7522(j) needs to be clarified to cover the Muskogee configuration

This language does not specifically cover the Muskogee situation where two boilers in the same subcategory vent into a common stack and it is not possible to test each unit individually. However, Equation 6 could also be used if two or more boilers emitted to the common stack and are in the same subcategory (the emission limit would merely be the same) and would cover the configuration at Muskogee and probably other mills.

GP urges EPA to change the language in §63.7522(j)(1) to read (changes in bold):
(1) Conduct performance tests according to procedures specified in § 63.7520 in the common stack if affected units from the same subcategory or other subcategories vent to the common stack. The emission limits that the group must comply with are determined by the use of equation 6...

Response: Section 63.7522 has beed edited to specifically clarify that situations where the exhaust of affectes units are each individually controlled and then sent to a common stack may utilize the common stack provisions of 63.7522(j).

Compliance Dates

Comment: It is apparent that owners and operators will be required to retrofit countless industrial boilers and process heaters in order to meet the final rule. The proposal would set a three-year compliance deadline for existing affected sources. However, this is an exceedingly short time given the extensive nature of the needed retrofits and the limited technical resources available to accomplish the retrofits (especially in light of the fact that industrial boiler owners will be competing for equipment and technical resources with other key industry sectors such as the utility sector, which will have a similar compliance deadline for the utility MACT and also will be required to install substantial air pollution controls to meet the proposed Clean Air Transport Rule).

To solve this problem, EPA must adopt a significantly longer compliance deadline. Nominally, EPA should adopt by rule an across-the-board one-year extension pursuant to § 112(i)(3)(B). However, even a four-year compliance period will be inadequate for many affected sources. Therefore, EPA should provide additional time by: (1) granting in the final rule a Presidential extension under § 112(i)(4), given that it is in the "national security interests of the United States" to prevent widespread noncompliance in the industrial base; (2) declaring that the statutory three-year compliance period is impossible to meet or otherwise produces "absurd results," which as demonstrated in EPA's recent PSD Tailoring Rule are doctrines that allow EPA to depart from clear statutory directives in appropriate circumstances; and/or (3) establishing phased or sequenced requirements such that certain element of the rule become effective no later than three years after promulgation (thus satisfying § 112(i)(3)(A)), while others are phased in at later times.

Comment: The planning, permitting, installation and compliance testing all within a three year time frame is unattainable. It has been our experience that permitting significantly less complex projects has taken in excess of 24 months. Facilities will be competing with other industries for qualified professionals, compliance equipment and stack testing services. This difficulty will be magnified when the Utility Boiler MACT is published in Spring 2011. In colder climate regions, the stack testing windows are shorter and make the schedule even more compact.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: Due to the broad scope of both the Area and Major Source Boiler MACTs, there will be significant demand for stack testing and installation of monitoring and control equipment. The Maine DEP is concerned that there will an insufficient supply of qualified testing companies to meet this demand within the proposed timeframes. We recommend that EPA allow one year for facilities to conduct initial compliance testing instead of the proposed 180 day period. We are also concerned that existing major sources will be unable to install the necessary control and monitoring equipment within three years. There will be high demand and limited supply for the required equipment, and many facilities will need to undertake significant designing, planning and construction to locate the equipment within the existing facility. We recommend that EPA establish a compliance date five years from the date the final rule is published.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: The proposed rules will create additional resource burdens on state and local permitting agencies that will have to issue several thousand Title V permit revisions, draft emission control regulations and submit them to EPA for review and approval under section 111 of the CAA. EPA can mitigate the burdern on state an local permitting agencies by specifically set out its expectations of state and local permitting authorities and incorporate reasonable timelines in its implementation schedule.

Response: EPA acknowledges the concerns of state governments but notes that although there are over 13,000 estimated boilers and process heaters, only approximately 1,500 boilers at approximately 700 facilities are subject to emission limits. The remaining units demonstrate compliance with the standard using work practice standards allowed for small, gas-fired, and limited use units. This is expected to reduce the burden on state and local permitting agencies. Regarding the commenter concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: Even under the best of circumstances, a major retrofit of a boiler takes years from project start to finish. EPA has estimated that the installation of an activated carbon injection control system on one combustion unit – a comparatively simple installation – takes about 15 months. (EPA, Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies (2002).) However, EPA expects a range of control devices will be used to meet the standards, including fabric filters, activated carbon injection, electrostatic precipitators, wet scrubbers, replacement burners, and combustion controls. EPA, Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters, 3-1 (April 2010) ("The control analysis considered fabric filters, carbon bed adsorbers, and activated carbon injection to be the primary control devices for mercury control, electrostatic precipitators for units meeting mercury limits but requiring additional control to meet the PM limits, wet scrubbers to meet the HCl limits, tune-ups, replacement burners, and combustion controls for CO and organic HAP control, and carbon injection for dioxin/furan control.") Further, the sheer number of boilers impacted by the rule will make finding – and then scheduling – the design and construction resources almost impossible. EPA estimates that there are approximately 13,555 units located at 1,608 facilities covered by this rule. 75 Fed. Reg. 32048. Given that EPA has set emissions standards that only a handful of existing units can currently meet, almost every single existing unit subject to an emission standard will need to be retrofitted. Retrofits will also be required to hundreds or thousands of area source boilers and units covered under the revised CISWI rule. Boiler owners will need to hire consultants to assist them in designing and performing the retrofit. Thus, across the multitude of industries impacted by this rule, boiler owners will be scrambling to find the very few qualified consultants who can perform the retrofits necessary to make boilers compliant with this stringent rule. There are a limited number of consulting companies with the expertise to assist in such retrofits, and they will likely be unable to assist all of the boiler owners in less than three years, especially when the electric utility industry will be competing for the same resources in order to comply with their own MACT standard. There will be a similar scarcity in equipment vendors, construction contractors, construction equipment (e.g., heavy lifting cranes), skilled labor (e.g., boilermakers), and other critical suppliers. Companies may even be unable to secure the basic building materials and control equipment (e.g., baghouses and scrubbers).

In order to retrofit a boiler, the owner will need to line up the capital necessary to pay for the retrofit. In these difficult economic times, just securing the necessary capital may take months, if not years, assuming the capital can be obtained from lending sources. In addition, the owner will need to go though the relevant permitting process(es), which will similarly take months, if not years. Finally, once the finances are secure and the permitting is complete, the owner will actually need to perform the retrofit. The design, procurement, installation, and shakedown of a retrofit project (e.g., installing a scrubber on a large boiler) can easily take more than three years. In addition, the timing of the retrofit work needs to be carefully planned, particularly for boilers that provide the primary and/or base load energy supply for their facilities. A facility owner will only shut down a boiler when everything is properly staged to ensure minimal disruption of the facility's operation. In addition to ensuring that the design work is completed and the control equipment and other supplies are on-site and ready for installation, the facility owner needs to make sure that the full suite of consultants and laborers are available for the installation. Based on a discussions with a number of potentially affected companies, the turnaround or shutdown cycles for boilers and process heaters at many of the facilities can be 1 to 5 years, making this type of precise staging exceedingly difficult to do in a three year period without substantial business interruption.

Finally, in many instances, the installation of pollution control equipment and associated charges to boiler must be permitted under state air pollution statutes and/or construction codes (building permits, etc.). The proposed rule will result in an increase in the number of permit applications, potentially swamping the state and local agencies, given the number of sources that will be making modifications as a result of the boiler and incinerator rules. Even in those areas where the rule may not result in significant increases in permitting work, the normal delays associated with permitting may make meeting the three year compliance deadline impossible.
In light of the difficulty in meeting a three year compliance deadline, EPA and authorized states should be prepared to readily grant one-year extensions under CAA § 112(i)(3)(B) to those units that have problems installing the necessary control equipment to comply with the industrial boiler MACT rule.

Comment: Although the rule should not mandate fuel switching or the use of certain fuels over others, EPA should establish an extended two-step compliance period for situations where a boiler owner voluntarily elects to replace or retrofit a boiler to burn a more readily compliant fuel source. (EPA, Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters, 3-1 (April 2010)) ("The control analysis considered fabric filters, carbon bed adsorbers, and activated carbon injection to be the primary control devices for mercury control, electrostatic precipitators for units meeting mercury limits but requiring additional control to meet the PM limits, wet scrubbers to meet the HCl limits, tune-ups, replacement burners, and combustion controls for CO and organic HAP control, and carbon injection for dioxin/furan control.") If a facility decides to switch to a different fuel, the replacement or retrofit work required to make that switch will potentially take years. Rather than require the facility to add emissions controls to its existing boiler in time for the proposed three year compliance deadline – likely eliminating the possibility that the facility would switch to a different fuel source – EPA should allow six years total for facilities to change their boilers and meet the MACT requirements for the different fuel source. This six year period would occur in two steps; a no-backsliding provision would apply for three years from publication of the rule in the Federal Register, and then the facility would have three years to comply with MACT standard for the subcategory for the cleaner fuel subcategory. EPA promulgated exactly this type of extended MACT compliance deadline for certain facilities that voluntarily elected to install new technology as part of the Pulp and Paper Cluster Rule. See Pulp and Paper Cluster Rule, 60 Fed. Reg. 18503, 18,508 (Apr. 15, 1998).(This two-step approach for the MACT standard is consistent with the D.C. Circuit's decision in NRDC v. EPA, 89 F.3d 1364 (D.C. Cir. 2007) (finding invalid EPA's decision to extend the compliance deadline for a promulgated MACT rule by a year because of the substantial changes that the agency made to the rule). Rather than functioning as an extension of the compliance deadline, this MACT standard for certain facilities would become applicable in two steps. For the first three years, a no-backsliding MACT standard would be applicable, then the three year deadline to implement the MACT standard for the applicable “cleaner” source would begin to run.) In addition to providing an incentive for facilities to switch to different fuel sources, this approach would reduce some of the competition for resources discussed above by extending the deadline to complete the work to replace or retrofit certain boilers.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 265

Comment: If EPA concludes that it cannot provide for an extended compliance period, this will not change the fact that facilities will have to install extensive emission control equipment to meet the emissions limits in the final rule. EPA itself stated in the preamble that, in order to meet the final rule, boilers would likely require a fabric filter (FF) plus carbon injection plus wet scrubber control plus combustion improvements or CO catalyst. The installation of this equipment could result in increases in emissions of CO_2 or other PSD regulated pollutants such that it is reasonable to expect that a substantial number of affected sources will need to get a PSD permit to install the controls or to otherwise take the measures that will be needed to meet the final rule. As noted above, obtaining a PSD permit is time consuming – typically anywhere from 12 to 24 months. Thus, the time needed to get a PSD permit (which must be obtained before construction actually begins) will consume one-third to two-thirds of the available compliance time under the Boiler MACT rule. The remaining time is patently insufficient for affected sources to construct and start up the needed controls. To alleviate this problem, EPA should invoke the “absurd results” or “administrative necessity” doctrines employed in the PSD GHG Tailoring Rule to provide that the MACT compliance period does not start to run until a final, non-appealable PSD permit has been issued.

Comment: Given the stringency of many of the emission limitations listed in the proposed rule, the Department is concerned that many facilities may not have sufficient time to engineer and design the emissions control systems, raise the amount of capital to purchase the equipment, and install the required equipment. In addition, there could be hardware backlogs and/or insufficient skilled labor, which could delay compliance. The Department asks that the Agency consider a lengthy compliance timeline which would allow facilities to achieve compliance within practical timelines.

Comment: COMPLIANCE DEADLINE. The Proposed Rule 63.7495(b) establishes a compliance deadline for existing sources as three years after the date of publication of the Final Rule in the Federal Register. It will be extremely difficult, if not impossible, for all of the entities with existing boilers to make the changes necessary to comply with this rule in the three year timeframe that EPA proposes. Many boiler owners, including the soda ash companies, are likely to be unable to secure equipment, slow down operations, and obtain the necessary state permits needed to retrofit their units within three years. In light of the difficulty in meeting a three year compliance deadline, EPA should encourage states to provide one-year extensions under CAA 112(i)(3)(B) to those units that have legitimate challenges with completing the installation of the pollution control equipment required to comply with the Proposed Rule.

Even under the best of circumstances, a major retrofit of a boiler takes years from project start to finish. That process will take even more time given the range of control devices EPA anticipates will need to be installed in order to meet these new emission limits including fabric filters, carbon bed adsorbers, activated carbon injection, electrostatic precipitators, wet scrubbers, replacement burners, and combustion controls. Given that EPA has set emissions standards that no existing unit can meet, every single existing unit subject to an emission standard throughout the country will need to be retrofitted. Boiler owners will have to compete for not only the required pollution control equipment but also qualified consultants and trained contractors to assist them in designing and performing the retrofit. They also will need to secure the necessary permits and find an appropriate time for the work to be done. The timing of a boiler shutdown is especially critical to the soda ash industry which, because of its location in remote southwest Wyoming, rely on multiple boilers as the primary energy supply for facility operations. It is simply unrealistic for EPA to conclude that sources will be able to meet the three year compliance deadline.

Comment: NGSB has determined that proposed limits would require construction of a new powerhouse. Even if NGSB were to begin design of a new, replacement powerhouse now — before the new regulation is finalized — the project would not be completed before 2015 under typical timelines for such a major project. New air permitting requirements, including PSD for greenhouse gases, could add two years to the schedule — two years during which no large equipment may be ordered and no construction completed. A crush of orders from the regulated community for new boilers and emissions control equipment resulting from the proposed regulation is expected to lead to abnormally long lead times. Furthermore, NGSB's three main powerhouse boilers could not all be shut down and replaced at one time; the units would need to be replaced sequentially, with sufficient time allowed between replacements to ensure reliable operation of each new boiler. Assuming the proposed rule is finalized in December 2010, it could be 72 months or more before new boilers could be in place at NGSB, commissioned, and made operational at a level to support facility operations.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 31

Comment: Proposed 63.7495(b) states If you have an existing boiler or process heater, you must comply with this subpart no later than [3 YEARS AFTER DATE THE FINAL RULE IS PUBLISHED IN THE FEDERAL REGISTER]. However, this is a major rulemaking [Footnote: As EPA states on page 32044 of the preamble, an initial screening analysis for impact on small entities indicated a likely significant impact for substantial numbers ...] and the Agency must provide 60 days for Congressional review. Thus, the effective date of the rule must be set at least 60 days after publication in the Federal Register and the compliance date should be 3 years after the effective date.

Recommendation: Provide time for Congressional Review of the final rule as required by the Congressional Review Act.

Response: We have modified the final rule language to incorporate the 60 day after publication of the rule as the effective date of the rule. We have still begun the three year compliance date for existing sources as three years after publication of the final rule in the federal register. The Congressional Review Act only specifies the effective date of the rule but it does not specify the compliance date of the rule as long as that date occurs after the effective date.

Commenter Name: Matthew Todd and David Friedman

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 32

Comment: It is apparent that, even with the changes suggested in these comments, owners and operators will be required to retrofit countless industrial boilers and process heaters with extensive controls in order to meet the emission limits in the final rule. The proposal would set a three-year compliance deadline for existing affected sources and even less compliance time for boilers and process heaters that began construction or reconstruction after the proposal date. Three years is an exceedingly short time given the extensive nature of the needed retrofits and the limited technical and supply resources available to supply the required controls and monitors and accomplish the retrofits, especially in light of the fact that industrial boiler and process heater owners will be competing for equipment and technical resources with area sources, CISWI sources and other key industry sectors such as the utility sector, which will have a similar compliance deadline for the utility MACT.

While this is not an issue for most refineries if the proposal not to impose emission limitations for Gas 1 units is finalized, it is a significant problem for non-refining major sources owned or operated by our member companies and a particular concern for refineries where liquid fuels must be used. For Gas 2 major sources and for individual refineries with significant liquid-firing, such as those without access to natural gas, installing multiple control technologies on tens of liquid-fired boilers and process heaters is simply not technically or economically feasible in three years. It is simply not possible to design, procure and install control equipment of this magnitude in three years, while a huge number of others are doing the same. Moreover, the installation of these controls requires shutdown of the process units that the boilers and process units service. Most such work is typically coordinated during major process unit turnarounds so that the economic penalty of an extra, enforced shutdown is not imposed. Five and six year turnaround schedules are typical for refineries. Thus, a three year compliance time would force many early shutdowns, incurring major production penalties and generating excess emissions and excess wastes, even assuming the additional facilities could be engineered and constructed in such a short time.

The shutdown penalty is a particular burden for remote, liquid-firing facilities. The reason natural gas is not available to these sources is the remoteness of their locations (e.g., Alaska, Hawaii, and Virgin Islands). Because they are remote, there are exceptional logistical difficulties beyond those typically encountered in the Continental U.S. and it is simply not possible to design, procure and install control equipment of this magnitude in three years.
To address this problem, EPA must adopt a significantly longer initial compliance deadline for both new and existing boilers and process heaters. Nominally, EPA should adopt by rule an across-the-board one-year extension pursuant to CAA section 112(i)(3)(B) for any unit subject to an emission limit under this regulation. However, even a four-year compliance period will be inadequate for many affected sources. Therefore, EPA should provide additional time by: (1) granting in the final rule a Presidential extension under CAA section 112(i)(4), given that it is in the national security interests of the United States to prevent widespread noncompliance in the industrial base; (2) declaring that the statutory three-year compliance period is impossible to

meet or otherwise produces absurd results, which as demonstrated in EPA's recent PSD Tailoring Rule are doctrines that allow EPA to depart from statutory directives in appropriate circumstances; and/or (3) establishing phased or sequenced requirements such that some elements of the rule become effective no later than three years after promulgation (thus satisfying CAA section 112(i)(3)(A)), while others are phased in at later times.

Recommendation: Provide up to five years for any unit subject to emission limits to comply with this rule.

Comment: Due to the complexity of this rule (multiple pollutant emission limits), it is requested that an automatic extension of 1 year be afforded in the rules, beyond the standard 3-year compliance schedule. This will allow sources with multiple boilers additional needed time to investigate availability of resources and equipment, and to spread capital and operating costs associated with complying with the rule. This is similar to what has been afforded to the pulp and paper industry MACT I, Phase 2 extended compliance time.

Boilers that installed controls for first Industrial Boiler MACT rule, or those that built new boilers to comply with the first MACT rule, should be allowed extensions to avoid having to spend capital again so soon.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: Availability of CO CEMS.
It appears that over 1000 CO CEMS might be required under this rule. This is a very high number that will be required over a short time period. EPA has provided no information or assurance that that number of units can be provided by suppliers. EPA should investigate this issue and allow for an extended compliance date if availability of CO CEMS is a problem.

Response: CO CEMS is no longer a requirement in the final rule. Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: Compliance Timeline
Compliance Deadline for Existing Sources.
EPA proposes to set the compliance deadline for existing affected sources at three years after the date of publication of the final rule in the Federal Register. 75 FR 32035. This provides an inadequate amount of time for the thousands of affected sources to be retrofitted as necessary to meet the new MACT standards. EPA estimates that 3,730 existing units will have to come into compliance with the proposed MACT standards. This is an unprecedented number of sources impacted by a MACT ruling. These units are all solid fuel-fired, i.e., predominantly coal-fired, units. In order to meet the MACT standards, owners will, by and large, have to install add-on controls.

We anticipate that industry will face severe time and material constraints that will make it extremely difficult, if not impossible, for many facilities to meet the retrofit deadline of three years. Most of the targeted solid fuel- fired units are located at facilities that will have to undergo substantial re-engineering, e.g., due to space constraints, to accommodate new controls. Design, procurement, installation, and shakedown of these projects will easily consume three years. In short, more time is needed. External factors will also jeopardize compliance within three years. A large number of companies will be competing nationwide for limited resources and materials from engineering consultants, equipment vendors, construction contractors, financial institutions, and other critical suppliers. This competition for limited resources will be compounded by the promulgation of the Clean Air Transport Rule, the Utility MACT, Regional Haze SIP's and/or FIP's at roughly the same period of time, which will introduce competition from electric utilities in addition to competition from other industrial boiler owners. Much of the pollution control equipment may not even be available within EPA's proposed compliance timeframe. By extending the compliance time, EPA would allow for the development of new creative technology to provide superior emissions control

It is likely many companies will find themselves unable to procure the necessary goods and services to complete the retrofitting of their affected units within three years. In particular, we anticipate problems procuring baghouses and scrubbers because immediate industry demand will outstrip immediately available supplies. For example, in preparation for compliance with the prio MACT, a scrubber project at one of CIBO's member facilities took four years to implement. Industry must continue to operate as best as possible while retrofitting to meet the new MACT standards. Construction on units will need to be staggered as facilities with multiple units will require equipment to be installed with units out of service. Staggering work on separate units a the same facility allows continued operation; however, this staggering extends the overall compliance time.

In general, the existing solid fuel-fired boilers that will be subject to this new rule comprise the most critical part of the base load energy supply for their facilities. These units typically have high capacity utilization rates. Extensive outages for retrofitting must be carefully planned. Only when all of the critical prerequisites for the retrofit have been lined up, e.g., the engineering is complete and the control equipment is staged for immediate installation, can an owner afford to shut down a facility's base load boiler to install the new controls. This takes planning and coordination both within the company and contractors.

Many units must conduct emissions testing prior to retrofitting units in order to determine the best means of achieving compliance. There are a limited number of emission testing contractors and laboratories capable of conducting this type of testing, which will further the delay. Where testing determines that emission limitations are unachievable and retrofitting is infeasible, it is possible they will decide to re-power or switch fuels. These additional processes would surely extend beyond the three year compliance timeframe proposed by EPA. Even under the best case scenario, undertaking a retrofit can take five years. Three years is simply not sufficient to allow owners of many of the affected sources the time necessary to make the retrofits without substantial disruption to the operation of their facilities.

The process to undertake a retrofitting project is more complex then EPA appreciates. Regulated sources need time to obtain capital funding. Some facilities will have to obtain capital funding for these projects thru a formal request process that by itself could last two years. Those facilities reliant upon the state funding process can only seek legislative approval when the rule is final.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: Robert D. Bessette

Comment Excerpt Number: 153

Comment: We recommend EPA address the foregoing problems by extending the compliance deadline to four years after the publication of the final regulations in the Federal Register. We believe the Agency would be fully justified in invoking § 112(i)(3)(B) to grant owners of all affected sources a one-year extension of the compliance deadline. Four years would provide critically needed time for industry to conduct the necessary retrofitting with controls and absorb the great cost of these retrofits. Given the magnitude of the retrofit requirements and the likelihood of substantial difficulties fulfilling these requirements, it is essential that EPA provide whatever relief may be possible.

There is established precedent for allowing sources more time to comply. Specifically, the final NESHAP for the Pulp and Paper Production source category includes an eight year compliance deadline. 63 FR 18519. Additionally, EPA extended the compliance date for the miscellaneous organics chemical manufacturing (MON) MACT. That standard was challenged in court with EPA and industry agreeing to a settlement. As part of the settlement, EPA extended the compliance deadline.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: 63.7505(g) specifies that for a new or reconstructed source that commenced construction or reconstruction between [INSERT DATE OF PUBLICATION OF THIS PROPOSED RULE IN THE FEDERAL REGISTER], and [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER], and you chose to comply with the proposed emission limits when demonstrating initial compliance, you must conduct a second compliance demonstration for the promulgated emission limits within 3 years after [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER] or within 3 years after startup of the affected source, whichever is later. However, per 63.6(b)(3) a source in this situation has three years from the effective date of the final rule to comply with the emission limitation in the final rule. Requiring the performance test before the three year compliance period is up significantly shortens the compliance period provided by the part 63 General Provisions and contravenes the normal requirement that the performance test be done within 180 days after achieving compliance.

Recommendation: Proposed 63.7505(g) should be revised to require the performance test within 180 days after the boiler or process heater complies with the final standard and no later than 3 years and 180 days after the effective date of the final rule.

Response: We have revised 63.7510 to address situations for new or reconstructed sources that commenced construction or reconstruction between proposal and promulgation of the final rule in order to be consistent with the general provisions 63.6(b)(3). We have also added a new Table 12 to the final rule to discuss the limits applicable to these new sources. Section 63.6(b)(3) only allows to three years after the effective date of the final standard if the owner or operator complies with the proposed standard during the 3-year period immediately after the effective date. In order demonstrate compliance with the proposed standard a unit must conduct its initial performance test on the same schedule as other new or reconstructed sources.

Comment Excerpt Number: 209

Comment: Demonstrating compliance on monthly basis for first 12 months is unworkable Compliance on a monthly basis during the first twelve months of compliance period is unworkable. Proposed 63.7522(f)(3) requires a facility to generate enough credits to offset the debits each and every calendar month up until 12 months are accumulated and, thereafter, determine compliance on a twelve month rolling average basis. This requirement unnecessarily restricts the utility of the emission averaging provision. For example, in the case where a facility over-controls one boiler while under-controlling the other, there will be months when the facility could not comply. This would certainly be true during a month when the credit-generating unit is down for its periodic maintenance outage. Due to the necessary length of these outages (4-6 weeks), there could conceivably be two or three months in a row where the facility could not comply with proposed averaging provisions. There will be other cases where the credit-generating unit experiences an unanticipated outage and the debit-generating unit is required to operate more to compensate.

For these reasons, this provision should be eliminated. CIBO notes that the HON, which EPA references, includes an annual emission test along with a quarterly emission test where the average emissions must be less than 130 percent of the allowable emissions. Here, EPA acknowledges that a short term average (quarterly) must provide some tolerance as compared to an annual average. CIBO brings this point up, not to suggest to EPA to adopt the HON quarterly test, but to illustrate that EPA emissions averaging provisions have accounted for this issue. Also, CIBO would note that the HON is written for an entirely different industry than the case of boilers and process heaters. Due to the circumstances described above (extended outages while other units take on additional load), a facility using emissions averaging for boilers and process heaters should be subject to only annual compliance determinations.

Response: See response to EPA-HQ-OAR-2002-0058-2824.1, excerpt 32 for response to comment on timing of first compliance demonstration.

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 218

Comment: Another complicating issue is that EPA has not provided guidance on what is required for BACT for CO2e. A tremendous amount of time and effort has gone into BACT determinations for criteria pollutants over last decade and an equal or larger effort will be required for BACT determinations for CO2e.

The timeline for compliance with Boiler MACT is to install emission control equipment by 2013. Permitting work for installation will be required two or more years prior to 2013, meaning that the PSD tailoring rule will apply to larger facilities within this time frame. Therefore, these larger facilities will have to evaluate whether or not the project to comply with Boiler MACT triggers PSD. In addition, smaller facilities may have to perform this evaluation out of an abundance of caution because there is no guarantee that the higher tailoring rule applicability threshold will be accepted due to the pending evaluation that states are making as to whether or not their laws with statutory thresholds of 100/250 ton per year can be changed. Further, pending legal challenges may result in statutory thresholds as well. Facilities that trigger PSD and their state regulators will be faced with BACT determinations for CO2e and in all likely-hood will have little-to-no guidance from EPA by then. Many states make no decisions about PSD without EPA guidance because they fear that EPA will not agree with their determinations or that some non-government organization will file a legal challenge. The result will be catastrophic because no decisions will be made and the facility will have no certainty for the capital required.

The theme of uncertainty is of critical importance because the long-term viability of a facility and its associated jobs is dependent on capital spending to ensure its continued competitiveness. Other developing countries have none of these rules thereby making investment (e.g. moving a U.S. facility's production to another country) financially attractive and there is far less uncertainty.

Response: The EPA disagrees with the commenters that the 3-year compliance deadline is too short considering the number of sources that will be competing for the resources and materials from engineering consultants, permitting authorities, equipment vendors, construction contractors, financial institutions, and other critical suppliers. We know that many sources subject to the standard are gas fired units or small boilers (less than 10 mmBtu/hr) and will not need to install controls in order to demonstrate compliance with the standard. As a result, since not everyone will need more than 3 years to actually install controls, the final rule does not allow an extra year for existing sources to comply with the final rule. Section 112(i)(3)(B) allows EPA, on a case-by-case basis to grant an extension permitting an existing source up to one additional year to comply with standards if such additional period is necessary for the installation of controls. The EPA feels that this provision is sufficient for those sources where the 3-year deadline would not provide adequate time to retrofit as necessary to comply with the requirements of the standard. EPA appreciates the other ongoing regulatory burden and uncertainty placed on industry and permitting authorities to address PSD and BACT issues with respect to greenhouse gas emissions. However, the three-year compliance deadline is a statutory requirement of Section 112.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 219

Comment: In order to remove some of this uncertainty, the EPA should categorically exempt projects required to comply with Boiler MACT from additional regulatory burdens such PSD. Alternatively, EPA should establish that the deadline for compliance with this rule be three years following the issuance of the required construction permits by a site's permitting authority. This would provide relief to the boiler owner in the event that the permitting authority is unable to issue the required permits in a timely fashion, whether due to uncertainty of BACT for CO2e determinations, or due to a backlog of permit applications that are anticipated due to the Tailoring Rule.

Response:
Three years after the effective date of the MACT standard is the maximum amount of time that the Clean Air Act provides for a source to come into compliance (see CAA Section 112(i)(3)(A)), and the Agency has provided that maximum amount of time. In accordance with CAA Section 112(i)(3)(B), EPA or a State with a program approved under title V of the Clean Air Act may issue a permit that grants up to one additional year to comply, if such time is necessary for the installation of controls.

Commenter Name: Robert Bauer
Commenter Affiliation: Kentucky Forest Industries Association
Document Control Number: EPA-HQ-OAR-2002-0058-3186.1
Comment Excerpt Number: 3

Comment: Sufficient compliance timelines
Given the stringency of many of the emissions limitations listed in the proposed rule, the Association is concerned that many facilities may not have sufficient time to engineer and design the emissions control systems, raise the amount of capital to purchase the equipment, and install the required equipment. In addition, there could be hardware backlogs and/or insufficient skilled labor, which could delay compliance. The Association asks that the Agency consider a lengthily compliance timeline which would allow facilities to achieve compliance within practical timelines.

Response: Three years after the effective date of the standard is the maximum amount of time that the Clean Air Act provides for a source to come into compliance (see CAA Section 112(i)(3)(A)), and the Agency has provided that maximum amount of time. In accordance with CAA Section 112(i)(3)(B), EPA or a State with a program approved under title V of the Clean Air Act may issue a permit that grants up to one additional year to comply, if such time is necessary for the installation of controls.

Comment Excerpt Number: 3

Comment: EPA should provide regulatory relief for the regulated community that has provided certification and documentation under 112 (J) filings with individual authorized state agencies to comply with the remanded Boiler MACT. EPA at a minimum, should give consideration to this regulated group with an extended compliance deadline recognizing the expenditures and continuing efforts made during the interim limbo status of the Boiler MACT. A three year extension beyond the proposed three year compliance deadline is suggested. The cost of

compliance testing, work practice controls, control technology changes and monitoring system installations to meet the proposed Industrial Boiler MACT standards are excessively high for the degree of emission reductions proposed. Averaging these costs over a period of time, may give some regulatory relief to this regulated group of boilers that has strived to achieve recognizable progress towards compliance with the remanded MACT.

Commenter Affiliation: JR Simplot Company
Document Control Number: EPA-HQ-OAR-2002-0058-3162
Comment Excerpt Number: 3

Comment: Compliance Dates
Within 3 years after the implementation of the proposed regulation, an affected source must achieve compliance with the applicable provisions in the rule.
It is anticipated that compliance will require installation of additional control equipment which in turn requires, capital equipment budgeting, design, selection, manufacturing time for the control equipment, and possibly air permitting. It is unclear that it is possible to achieve compliance within 3 years. In particular, obtaining any necessary air permits in a timely matter has been an ongoing issue in a number of areas where Simplot does business in the United States.

Commenter Name: Jeffrey R.Klieve
Commenter Affiliation: Monsanto Company
Document Control Number: EPA-HQ-OAR-2002-0058-2754.1
Comment Excerpt Number: 4

Comment: Proposed Compliance Timeframe (75 Fed. Reg. 32050)

Monsanto is concerned with the proposed timeframe for compliance with the MACT standards for existing affected units. The current rule, as written, will affect thousands of major sources and an equal or greater number of area sources -all with the same compliance time frame. The demand on vendors of air pollution control equipment and continuous emission monitoring systems, as well as service firms such as consultants and stack testing firms, will vastly exceed current nation-wide capabilities. This demand on resources could also be exacerbated by pending regulations aimed at reducing air emissions from the electric utility generating sector.

If additional air pollution control equipment is required to meet the final emission limitations, Monsanto requests that USEP A consider a compliance time frame of 5 years or more to allow for proper planning, design, procurement, installation and final startup of the air pollution control and related equipment.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: H. Allen Faulkner
Commenter Affiliation: Ascend Performance Materials, LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2743.1
Comment Excerpt Number: 5

Comment: Ascend requests the EPA to reconsider the 3-year compliance date for this rule. Currently, there is no proven control technology identified to reduce Dioxin/Furan emissions from coal fired boilers. While equipment vendors have stated that control equipment could have a 2 year lead time, they are also reluctant to guarantee control equipment specifications to the emission levels identified in the rule for all pollutants. These factors make it extremely difficult for companies to engineer and order the appropriate control equipment within the required 3-year compliance period.

These new limits are neither demonstrated nor accurately measurable and that is a source of tremendous concern for us. We have worked diligently over the years to maintain compliance of our assets through imaginative and diligent application of proven scientific principles. Since there are no proven technologies to measure or achieve all limits on a single boiler, we ask the Agency to consider a longer compliance period, perhaps 5 years, to allow industry to develop and validate the systems and supply chains that are necessary to meet this new challenge.

Response: See the preamble for discussion of dioxin/furan work practice standards. Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: Frank Kohlasch
Commenter Affiliation: Minnesota Pollution Control Agency

Document Control Number: EPA-HQ-OAR-2002-0058-2773.1
Comment Excerpt Number: 5

Comment: Provide as much time as the law allows for compliance. The MPCA recognizes that for some boiler or process units, substantial air pollution control upgrades are needed to comply with the proposed rules. Given the number of affected units and the simultaneous need for engineering, construction, finance and other technical services throughout many different industrial sectors, EPA should allow as much time as possible for facilities to achieve compliance. Section 112(i)((3)(b) allows the Administrator or a state with an approved Title V program) to provide a one year extension of the compliance deadline if the extension is deemed necessary to install controls. It would be valuable to states if EPA would include in the final rule the required evidence of affected source would submit to support granting an extension. A deadline for submitting a request would be valuable in aiding states' ability to process requests in a timely manner.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: Air construction permits will be required for these changes in South Carolina. The pending uncertainly and complexity of green house gas regulation under the Clean Air Act and the Tailoring Rule will be added to this process and SCPPA is concerned South

Carolina Department of Health and Environmental Control and EPA will not be able to issue permits in a timely manner.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: Eric Trauner
Commenter Affiliation: Citizen
Document Control Number: EPA-HQ-OAR-2002-0058-2768
Comment Excerpt Number: 7

Comment: The date for compliance should be set at five years, not three. By definition, there will be facilities that will not be able to comply with this MACT. Intelligent consideration of compliance options in such cases has many steps, each taking several months. For instance, it will take several weeks for a facility to review the final MACT and develop a compliance plan.

A likely first step in such a compliance plan would be evaluation of current status, likely by stack testing. Because there are in fact a limited number of stack testers genuinely qualified to execute such work, even this seemingly simple step of compliance determination will take several months (as US-EPA has recently learned). Then, a review of compliance options in terms of engineering and economics will also take several months to a year. Hard engineering design can take an additional year or longer, followed by what could well be two years for acquisition of equipment, installation, and start-up/ shakedown, with a final official stack test. A sound compliance effort cannot be completed in three years.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment Excerpt Number: 24

Comment: Given the tens of thousands of boilers that will have to be controlled as a result of these rules, it is unlikely that the capacity of existing vendors, contractors, engineers, and state regulatory personnel is sufficient to allow completion of all of the required modifications in a 3-year time period, or even a 4-year time period if facilities were granted a 1-year extension. EPA should evaluate all of the necessary capabilities and establish a compliance period based upon that evaluation.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 25

Comment: Compliance Time
EPA proposes to set the compliance deadline for existing affected sources at three years after the date of publication of the final rule in the Federal Register. Duke Energy believes this provides an inadequate amount of time for the thousands of affected sources to be retrofit as necessary to meet the new MACT standards. When finalized, EPA estimates that under the

alternative solid waste definition, the MACT standards will apply to the existing fleet of 525 coal units, 239 biomass units, 791 liquid fired units and 11,524 gas fired units. The capital costs will fall predominately to those industries which have solid fuel-fired, i.e., predominantly coal-fired, and bio-mass units. In order to meet the MACT standards, these owners will, by and large, have to install add-on controls. According to Table 9, out of a total of 13,079 existing units that will require controls, 764 are solid fuel fired, or about 6% of the total. The solid fuel fired units will require a capital investment of $5.1 billion out of the total $8.0 projected capital cost. While not discussed in detail in these comments, Duke Energy believes that EPA has significantly underestimated the capital cost of compliance with these rules. What is equally puzzling is that EPA projects in Table 11 that the rules will apply to only 46 new units. Duke Energy believes that this number is grossly understated since many solid fuel fired units may be forced by economics to shutdown and repower with new boilers fired by natural gas or other fuels. More egregiously, many of these sources will alternatively decide to shut down permanently.

Response: The EPA disagrees with the commenters that the 3-year compliance deadline is too short considering the number of sources that will be competing for the resources and materials from engineering consultants, permitting authorities, equipment vendors, construction contractors, financial institutions, and other critical suppliers. We know that many sources subject to the standard are gas fired units or small boilers (less than 10 mmBtu/hr) and will not need to install controls in order to demonstrate compliance with the standard. As a result, since not everyone will need more than 3 years to actually install controls, the final rule does not allow an extra year for existing sources to comply with the final rule. The commenter incorrectly notes that 13, 079 existing units will require controls, many of these units are gas-fired units, limited use units, or small units that will demonstrate compliance with a work practice standard. Further, EPA has consolidated the proposed subcategories for biomass and coal into a single solid fuel subcategory for fuel based HAP in order to address concerns with multifuel units. This consolidation is also expected to reduce the number of units requiring add-on controls for HCl emission limits. See the response to comments made in the new unit projection section for the estimated number of new solid fuel boilers. Section 112(i)(3)(B) allows EPA, on a case-by-case basis to grant an extension permitting an existing source up to one additional year to comply with standards if such additional period is necessary for the installation of controls. The EPA feels that this provision is sufficient for those sources where the 3-year deadline would not provide adequate time to retrofit as necessary to comply with the requirements of the standard.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 26

Comment: Duke Energy anticipates that industry will face severe time and material constraints that will make it extremely difficult, if not impossible, for many facilities to meet the retrofit deadline of three years. Most of the targeted solid fuel-fired units are located at facilities that will have to undergo substantial re-engineering, e.g., due to space constraints, to accommodate new controls. Design, procurement, installation, and shakedown of these projects will easily consume three years. In short, more time is needed. Moreover it is inevitable that many existing boilers will be forced to convert to an alternative fuel such as natural gas, or even construct entirely new boilers. According to its rulemaking to date, EPA has not adequately considered these factors.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 27

Comment: External factors will also jeopardize compliance within three years. A large number of companies will be competing nationwide for limited resources and materials from engineering consultants, equipment vendors, construction contractors, financial institutions, and other critical suppliers. It is likely many companies will find themselves unable to procure the necessary goods and services to complete the retrofitting of their affected units within three years. In particular, Duke Energy is concerned about sources being able to procure bag houses and scrubbers because immediate industry demand will outstrip immediately available supplies.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 28

Comment: EPA must also realize that these retrofits will not occur in a vacuum. Because of EPA's recently proposed Transport Rule and the forthcoming Utility MACT Rule, a large amount of

retrofits will occur at the same time sources are attempting to meet the requirements of the Industrial Boiler MACT. Since many industrial boilers and process heaters can be relatively small sources, it is plausible that they will suffer from lower priorities compared to larger utility boilers.
Industry must continue to operate as best as possible while retrofitting to meet the new MACT standards. In general, the existing solid fuel-fired boilers that will be subject to this new rule comprise the most critical part of the base load energy supply for their facilities. These units typically have high capacity utilization rates. Extensive outages for retrofitting must be carefully planned. Only when all of the critical prerequisites for the retrofit have been lined up, e.g., the engineering is complete and the control equipment is staged for immediate installation, can an owner afford to shut down a facility's base load boiler to install the new controls. This will take careful planning and coordination both within the company and outside the company that will involve with engineering consultants, equipment vendors, and construction contractors. Duke Energy does not believe three years is sufficient to allow owners of many of the affected sources the time necessary to make the retrofits without substantial disruption to the operation of their facilities.

Response: Three years after the effective date of the standard is the maximum amount of time that the Clean Air Act provides for a source to come into compliance (see CAA Section 112(i)(3)(A)), and the Agency has provided that maximum amount of time. In accordance with CAA Section 112(i)(3)(B), EPA or a State with a program approved under title V of the Clean Air Act may issue a permit that grants up to one additional year to comply, if such time is necessary for the installation of controls.

Comment Excerpt Number: 30

Comment: Duke Energy recommends EPA extend the compliance deadline to four years after the publication of the final regulations in the Federal Register. Duke Energy believes that the Agency would be fully justified in invoking 112(i)(3)(B) of the Clean Air Act to grant owners of all affected sources a one year extension of the compliance deadline. Four years would provide critically needed time for industry to conduct the necessary retrofitting with controls and absorb the great cost of these retrofits. Given the magnitude of the retrofit requirements and the likelihood of substantial difficulties fulfilling these requirements, it is essential that EPA provide all the flexibility within their authority. The one year compliance extension authorized by the Act is a legitimate and necessary solution to this problem, and Duke Energy urges EPA to incorporate a general one year compliance extension for existing affected sources in the final BPH MACT rule. In addition EPA must clearly articulate the conditions under which a source is eligible for this extension at the time that the rule is finalized. If it is uncertain that a source can qualify for an extension or it must go through an uncertain regulatory approval process, there is no way a source can effectively factor that extension into its planning process and risk possible noncompliance. Duke Energy supports giving this extension to all sources that actually install controls to attain compliance.

Commenter Name: David Bonistall
Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 33

Comment: The timeline for compliance with Boiler MACT will most likely require installation of emission control equipment by 2013. Permitting work for installation will be required two or more years prior to 2013, meaning that the PSD tailoring rule will apply to larger facilities within this time frame. Therefore, these facilities will have to evaluate whether or not the project to comply with Boiler MACT triggers PSD. In addition, due to the pending evaluation that states are making as to whether or not their laws with the statutory thresholds of 100/250 ton per year can be changed. Further, pending legal challenges may result in statutory thresholds as well. Facilities that trigger PSD and their state regulators will be faced with BACT determinations for GHGs and in all likelihood will have little-to-no guidance from EPA. Many states make no decisions about PSD without EPA guidance because they fear that EPA will not agree with their determinations or that some non-government organization will file a legal challenge. The result will be catastrophic because no decisions will be made and the facility will have no certainty for the capital required. In addition, with the uncertainty surrounding GHG BACT, facilities will also not have certainty for the timeline for obtaining the permits needed to make the changes required for Boiler MACT compliance. The PSD permitting process is notorious for having a long timeline and since construction cannot begin until all penult approvals are obtained, any further delays in the PSD process could jeopardize a facility meeting the compliance dates.

Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 34

Comment: Even with the changes suggested in our comments, owners and operators will be required to retrofit a significant number of industrial boilers in order to meet the final rule. The proposal would set a three-year compliance deadline for existing affected sources. However, this is an exceedingly short time given the extensive nature of the needed retrofits and the limited technical resources available to accomplish the retrofits (especially in light of the fact that industrial boiler owners will be competing for equipment and technical resources with other key industry sectors such as the utility sector, which will have a similar compliance deadline for the utility MACT and also will be required to install substantial air pollution controls to meet the proposed Clean Air Transport Rule).

To solve this problem, EPA must adopt a significantly longer compliance deadline. EPA should adopt by rule an across-the-board one-year extension pursuant to 112(i)(3)(B). However, even a four-year compliance period will be inadequate for many affected sources. Therefore, EPA should provide additional time by: (1) granting in the final rule a Presidential extension under 112(i)(4), given that it is in the "national security interests of the United States" to prevent widespread noncompliance in the industrial base; (2) declaring that the statutory three-year compliance period is impossible to meet or otherwise produces "absurd results," which as demonstrated in EPA’s recent PSD Tailoring Rule are doctrines that allow EPA to depart from clear statutory directives in appropriate circumstances; and/or

(3) establishing phased or sequenced requirements such that certain element of the rule become effective no later than three years after promulgation (thus satisfying 112(i)(3)(A)), while others are phased in at later times.

Comment Excerpt Number: 1

Comment: GP has 84 solid fuel and oil-fired boilers subject to Boiler MACT and it is anticipated that all but 2 of these boilers will require addition of one or more add-on devices or modifications/upgrades to combustion systems to meet the proposed limits. The normal duration of GP major capital projects from initial concept to completion is 3 years, consisting of 1 year for technology review and vendor/equipment selection, 1 year for engineering and equipment manufacturing, and 1 year for construction, startup, commissioning and compliance testing. There are a number of factors that will make it very difficult to get all 82 units in compliance within the proposed 3 year time frame.
* Resource limitations
o Internal – The GP corporate engineering group is currently staffed to manage 2-3 major boiler projects at a time. Even if external engineering resources are hired to augment internal resources, we would still need GP engineering/project management to manage and supervise the external resources. Mill staffs can typically manage 1-2 ongoing boiler projects at a time and some of the mills will have as many as 5 boilers that will be impacted by Boiler MACT. Attempting to manage 82 projects concurrently will increase the cost of compliance due to errors and inefficiency.
o External – There are limited engineering, manufacturing and construction resources to design, manufacture and install the required control equipment. All of industry will be placing demand on these resources at the same time. This situation is worse than it normally would be due to the fact that the economy is coming out of a major recession and many of these companies may have significantly reduced their workforce.
o Utility MACT – The utility version of Boiler MACT is expected to go into effect one year after industrial Boiler MACT. Since utilities and industry share the same engineering, manufacturing and construction resource base, we will be competing with the utilities for these resources. The inherent larger size of utility projects will make it difficult for industrial companies to compete.
* Outage scheduling – Large pulp and paper mills with multiple boilers typically stagger boiler outages throughout the year due to resource constraints and to minimize the impact on production. In facilities with multiple boilers requiring addition of control devices, it will be necessary to complete some of the installations as much as 12-15 months prior to the compliance deadline which will significantly compress the normal schedule duration and place additional stress on limited resources.

Comment: EPA should provide regulatory relief for the regulated community that has provided certification and documentation under 112 (J) filings with individual authorized state agencies to comply with the remanded Boiler MACT. EPA at a minimum, should give consideration to this regulated group with an extended compliance deadline recognizing the expenditures and continuing efforts made during the interim limbo status of the Boiler MACT. A three year extension beyond the proposed three year compliance deadline is suggested. The cost of compliance testing, work practice controls, control technology changes and monitoring system installations to meet the proposed Industrial Boiler MACT standards are high for the degree of emission reductions proposed. Averaging these costs over a period of time may allow for some regulatory relief for this regulated group of boilers whose owners/operators have strived to achieve recognizable progress towards compliance with the remanded MACT.

Comment: There is real-life difficulty in meeting a three year compliance deadline for an overwhelming number of major projects, EPA must extend the compliance date beyond three years and even beyond the one-year extensions authorized by 40 CFR §63.6(i)(4)(i). As noted in the AF&PA comments, EPA has several options for accomplishing a significantly longer compliance deadline including (1) a Presidential extension under §112(i)(3)(B) of the CAA, (2) declaring that the statutory deadline is impossible to meet or would produce “absurd results”, and/or (3) establishing phased or sequenced requirements.

Comment: The regulatory impacts of these rules may take effect sooner than EPA anticipates because the Definitions Rule implementation schedule is unclear. It is unclear whether or not the Definitions Rule requirements apply earlier than the Boiler/Process Heater MACT, Area Source Boiler Rule and CISWI proposals. Thus materials may need to be diverted much sooner than the applicability dates of the Boiler/Process Heater MACT, Area Source Boiler Rule and CISWI in order to comply with the effective date of the Definitions Rule. In that event, permitting revisions to authorize the change in materials burned would be necessary.

Commenter Affiliation: Celanese International Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2840.1
Comment Excerpt Number: 15

Comment: The proposed compliance deadline in the rule is unreasonable and should be extended by an additional 2 years.

EPA should use the discretion it has under the Clean Air Act to provide a longer compliance period than the 3 year period in the proposed rule. Celanese recognizes that newly promulgated NESHAP regulations have traditionally specified a 3-year compliance schedule (with the potential for an additional year). In most previously promulgated NESHAP, this period was sufficient to allow for compliance. However, due to several factors, we feel that the traditional period is inadequate for the proposed regulation.

A significant amount of testing will be required by sources to determine the compliance status with respect to the rule and to evaluate and select available control strategies. Capital projects to install necessary control equipment cannot proceed until the testing and evaluation is complete. Due to the high number of sources affected by the rule that have the same concerns, it is likely that availability of stack testing personnel and laboratory facilities to conduct tests will be limited, adding to the time required to complete this essential first step.

The proposed rule will likely require control equipment to reduce very dilute concentrations of pollutants (such as dioxins). Control equipment vendors have little to no experience at designing controls for such low concentrations, and a period of research and development will be required to design adequate control strategies. This situation is different from most NESHAPs that have been proposed to date where the technology for the required emission reductions was well-known and demonstrated.

To comply with the proposed regulation, Celanese may choose to replace coal-fired boilers at one of its sites with natural gas-fired units. In addition to the lengthy process to obtain capital, design, permit, and install the boilers, the site is located in an area that is not adequately served by natural gas distribution system, and will require construction of an entirely new 16-mile pipeline to provide sufficient natural gas. Such a project will require an extensive and time-consuming permitting process.

Boilers and process heaters are somewhat unique in that they are essential to most portions of a plant, and projects to upgrade or replace boilers will need to occur during scheduled plant-wide shutdowns. There are limited windows of opportunity for such shutdowns, which will serve to lengthen the time needed to implement them.

Comment: EPA Should Extend the Compliance Deadline for Existing Affected Sources.
EPA proposes to set the compliance deadline for existing affected sources at 3 years after the date of publication of the final rule in the Federal Register. We believe this provides an insufficient amount of time for the thousands of affected sources to be retrofitted as necessary to meet the new MACT standards. EPA estimated that 3,730 existing units will have to come into compliance with the proposed MACT standards. This is an unprecedented number of sources impacted by a MACT ruling. These units are all solid fuel-fired, mostly coal-fired, units. In order to meet the MACT standards, owners will, by and large, have to install add-on controls. The additional controls installed to meet the previously vacated Boiler MACT are likely not sufficient to meet the emission limits of the proposed rule, so additional controls will be necessary. Experience with the previously vacated Boiler MACT has demonstrated that this timeline is not adequate to conduct the required emissions testing and engineer and install additional controls for these units.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: We anticipate severe time and material constraints that will make it extremely difficult, if not impossible, to meet the retrofit deadline of 3 years. Design, procurement, installation, and shakedown of these projects will easily consume 3 years. More time is needed for this. External factors such as the large number of companies competing for limited resources and materials from engineering consultants, equipment vendors, construction contractors, financial institutions, and other critical suppliers will also jeopardize the 3-year compliance deadline.
It is likely we will be unable to procure the necessary goods and services to complete the retrofitting of affected units within 3 years. We anticipate problems procuring scrubbers because immediate industry demand will outstrip immediately available supplies. In addition, we must continue to operate as best as possible while retrofitting to meet the new MACT standards. The existing solid fuel-fired boilers that will be subject to this new rule comprise the most critical part of the base load energy supply for our facilities. Units typically have high capacity utilization rates, and extensive outages for retrofitting must be carefully planned.
We do not believe 3 years is sufficient to allow us the time necessary to make the retrofits without substantial disruption to the operation of our facilities.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: Gary W. Kruger

Comment: PSD Tailoring Rule - The facility upgrades needed to comply with the boiler MACT must be exempted from the PSD Tailoring Rule to be able to meet the boiler MACT compliance schedule.
Facilities will have to install extensive emission control equipment to meet the proposed Boiler MACT emission limits. Specifically, EPA stated in the preamble that emission control would likely require a fabric filter (FF) plus carbon injection plus wet scrubber control plus combustion improvements or carbon monoxide (CO) catalyst. These installations will be long, involved engineering projects that will be difficult to complete in the 3 year compliance timeframe, particularly given that most facilities must continue to operate during the upgrades. Many facilities have numerous boilers which cannot be shutdown simultaneously, so the equipment installation will start well before the end of the three years. This will create significant challenges, which could become impossible to overcome if regulatory hurdles, uncertainty or inactions occur. Therefore the facility upgrades needed to comply with the boiler MACT must be exempted from the PSD Tailoring Rule to be able to meet the boiler MACT compliance schedule.
The installation of the extensive emissions control equipment could result in increases in emissions of CO_2 or another criteria pollutant. The following are examples:
e
(1) In general the installation of additional emission control equipment will increase the pressure drop that a boiler's induced draft (ID) fan will have to overcome. If the ID fan is not upgraded the boiler steaming capacity will decrease because the previous air–to-fuel ratio cannot be

achieved resulting in the requirement to increase the firing rate of the other facility boilers. Combustion of additional fuel in the other on-site boilers may result in a significant emissions increase triggering PSD.
(2) Operation of additional emissions control equipment will require more electricity. A facility's unused electrical generating capacity would be required to meet this demand thereby requiring additional fuel combustion. Combustion of additional fuel may result in a significant emissions increase triggering PSD.
Facilities may be required to make operational changes in order to meet the Boiler MACT limits that could result in increases in emissions of CO_2 or another criteria
e
pollutant. The following are examples:
(1) Fuel switching for multi-fuel boilers may be required to meet the proposed boiler MACT emission limits. A specific example is multi-fuel (e.g. wood and some coal) boiler that has over-fired air that decreases emissions of CO and it must combust additional coal in order to further decrease the emissions of CO. This change in firing ratio of fuels may result in a significant increase triggering PSD.
(2) A biomass boiler may have to increase its operating target for excess oxygen level in order to decrease emissions of CO in order to meet the proposed boiler MACT emission limit. The result is that the flue gas flow rate increases to a level that is beyond the capability that existing fabric filter can handle reliably and the amount of fuel that can be burned in this boiler is now administratively limited to match the capability of the fabric filter. This requires that the facility operate the back-

up natural gas package boilers which have no heat recovery system (e.g. economizer or air heater) to make-up the difference rather than invest in a larger
fabric filter needed to meet the proposed Boiler MACT limits. This change requiring additional combustion of natural gas may result in a significant increase triggering PSD.
There are many other ways that the PSD tailoring rule could be triggered due to changes that facilities must make to achieve compliance with the proposed Boiler MACT rule.
Another complicating issue is that EPA has not provided guidance on what is required for BACT for CO2e. A tremendous amount of time and effort has gone into BACT determinations for criteria pollutants over the last decade and an equal or larger effort will be required for BACT determinations for CO2e.
The timeline for compliance with Boiler MACT is to install emission control equipment by 2013. Permitting work for installation will be required two or more years prior to 2013, meaning that the PSD tailoring rule will apply to larger facilities within this time frame. Therefore, these larger facilities will have to evaluate whether or not the project to comply with Boiler MACT triggers PSD. These evaluations are very complicated and take time to ensure the facility retains the maximum operating flexibility possible due to the compounding effect of changes to all the boilers at a facility. Decreasing one pollutant may increase another, and addition of controls to decrease the increased pollutant may require other operational changes. In addition, smaller facilities may have to perform this evaluation out of an abundance of caution because there is no guarantee that the higher tailoring rule applicability threshold will be accepted due to the pending evaluation that states are making to determine whether their statutory thresholds of 100/250 ton per year can be changed. Pending legal challenges may also result in lower thresholds as well. Facilities that trigger PSD and their state regulators will be faced with BACT determinations for

CO2e and in all likely-hood will have little-to-no guidance from EPA at that time. Many states make no decisions about PSD without EPA guidance because they fear that EPA will not agree with their determinations or that some non-government organization will file a legal challenge. The result will be catastrophic because no decisions will be made and the facility will have no clear decisions at the time money needs to be spent to purchase and install equipment.
The theme of uncertainty is of critical importance because the long-term viability of a facility and its associated jobs are dependent on capital spending to ensure its continued competitiveness. Developing countries have none of these rules thereby making investment (e.g. moving a U.S. facility's production to another country) financially attractive and there is far less uncertainty.
In order to remove some of this uncertainty, the EPA should categorically exempt projects required to comply with Boiler MACT from additional regulatory burdens such as PSD. A less desirable alternative is allowing an extended compliance timeline for a Boiler MACT project that triggers PSD. This can be facilitated by starting the three year compliance timeline for Boiler MACT when the construction permit (or Title V permit modification) is issued by the administrative authority. This approach ensures that the affected source and state have come to agreement on permit requirements (e.g. stakeholders have sufficient BACT guidance and associated information) and it provides time for installation of a well engineered project that will meet all the regulatory requirements.

Comment Excerpt Number: 26

Comment: EPA should allow postponement of stack testing if it is not possible to burn alternative fuels. The rule should be modified to incorporate an option to request an extension for completion of the performance test if a facility currently does not have a fuel onsite. Several of our sites are permitted to burn fuel oil, but do not currently have it available onsite. If the price of natural gas rises dramatically, we will need to convert quickly to burning fuel oil. Allowing an extension of time in the rule will help the facility adjust to adverse economic situations while still ensuring air quality protection.

Response: The facility is responsible for demonstrating that they are able to continuously comply with the emissions limits when operating under expected operating conditions. If a stack test does not represent the range of combined process and control measure conditions under which the facility expects to operate, the delegated agency may determine that retesting is warranted. EPA notes that the agency will have three years to obtain liquid fuel to the site if a facility identifies certain units as belonging to the liquid fuel subcategory. The final rule has added several provisions to accommodate periodic use of liquid fuels, without subjecting a unit to the liquid fuel subcategory. For example, if a unit only fires liquid fuels during periods of gas curtailment or emergency, or periodic testing, the unit would be in the gas 1 subcategory (which does not have emission limits) and it would be unnecessary to conduct performance testing on the liquid fuel. If the unit routinely fires liquid fuels, it is expected that the facility could obtain necessary fuel supply in order to demonstrate compliance with the standards.

Comment Excerpt Number: 28

Comment: IDEA believes EPA's current schedule, with promulgation by December 16, 2010 is inadequate for the necessary evaluations, deliberations, and revisions that are needed to this Proposed Rule. This rule in combination with the three other proposed combustion rules presents the largest set or rulemakings from an impact and cost perspective that EPA has ever issued. As such, the cost and potential impact on jobs in the US demand a thorough deliberation and thought process so that the most reasonable and defensible rule can be finalized that meets the intentions of the Clean Air Act. Requiring EPA to do all of the work required in less than 4 months puts EPA in an untenable position and the results of having too little time will be a less than optimum regulatory result.

Further, given both the significant cost for design and construction of facilities to meet the standards and the current constraints on access to capital (particularly for colleges, universities and other institutions), the three year deadline for compliance will be onerous.

Document Control Number: EPA-HQ-OAR-2002-0058-2938.1
Comment Excerpt Number: 29

Comment: EPA Should Provide for a Compliance Period Longer Than 3 Years. It is apparent that, even with the changes suggested above, owners and operators will be required to retrofit countless industrial boilers and process heaters in order to meet the final rule. The proposal would set a three-year compliance deadline for existing affected sources. However, this is an exceedingly short time given the extensive nature of the needed retrofits and the limited technical resources available to accomplish the retrofits. In addition, industrial boiler owners will be competing for equipment and technical resources with other key industry sectors such as the utility sector, which will have a similar compliance deadline for the utility MACT and also will be required to install substantial air pollution controls to meet the proposed Clean Air Transport Rule.

To solve this problem, EPA must adopt a significantly longer compliance deadline. Nominally, EPA should adopt by rule an across-the-board one-year extension pursuant to § 112(i)(3)(B). However, even a four-year compliance period will be inadequate for many affected sources. Therefore, EPA should provide additional time by: granting in the final rule a Presidential extension under § 112(i)(4), given that it is in the "national security interests of the United States" to prevent widespread noncompliance in the industrial base; declaring that the statutory three-year compliance period is impossible to meet or otherwise produces "absurd results," which as demonstrated in EPA's recent PSD Tailoring Rule are doctrines that allow EPA to depart from clear statutory directives in appropriate circumstances; and/or establishing phased or sequenced requirements such that certain element of the rule become effective no later than three years after promulgation (thus satisfying § 112(i)(3)(A)), while others are phased in at later times.

Comment: The magnitude of the engineering task alone to research the capabilities of technologies to achieve such stringent proposed standards, assess compliance approaches and conduct engineering assessments to determine the feasibility of achieving compliance and the estimated cost to do so is easily a 6 month project even on a fast track. Control options conceivably needed to achieve proposed limits have never been applied to boilers of the size and design of those common to the pulp and paper industry (e.g., combustion catalysts and carbon impregnated filters for dioxins) and actual research is needed to assess feasibility. Then, because fuels may become unavailable for use as solid wastes or may be needed to assure compliance (e.g., natural gas), there is the need to assess availability of alternative fuels and consider the infrastructure needed to deliver and use them.

EPA must provide adequate implementation time, beyond the typical three year compliance window, to allow for transitioning away from alternative fuels, if necessary, and sufficient time to allow for the deluge of facilities who will call upon boiler and control system specialty firms to do the herculean task to retrofit tens of thousands of combustion units all across the country while minimizing economic impact on a fragile US economy. More time will definitely be necessary so that permitting of new and/or modified equipment can also occur. The dollars associated with complying with this suite of rules competes with the dollars that are also necessary to meet other EPA initiatives such as GHG, water and other air initiatives. The pool of available dollars is not without limits.

Comment: Another reason we believe that treatment under Section 125(h) is warranted is that installing multiple control technologies on 23 oil fired units at HOVENSA is simply not technically or economically feasible in the three years (plus one possible year of extension) provided by the Clean Air Act. The logistical difficulties of construction in remote areas were outlined above, and it is simply not possible to design, procure and install control equipment of this magnitude in the three years allowed.
Moreover, as discussed in detail above, the installation of these controls requires shutdown of the units that they service. Installation would have to be done unit by unit (shutting the refinery down is impractical and the logistics of installing 23 units' add-on controls all at once is also impractical). Doing this in addition to engineering and procurement in the space of 3 years is just not physically possible.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment Excerpt Number: 42

Comment: It is apparent that, even with the changes suggested above, owners and operators would be required to retrofit countless industrial boilers and process heaters in order to meet the final rule. The proposal would set a three-year compliance deadline for existing affected sources. However, this is an exceedingly short time given the extensive nature of the needed retrofits and the limited technical resources available to accomplish the retrofits (especially in light of the fact that industrial boiler owners would be competing for equipment and technical resources with other key industry sectors such as the utility sector, which would have a similar compliance deadline for the utility MACT and also would be required to install substantial air pollution controls to meet the proposed Clean Air Transport Rule).

To solve this problem, EPA must adopt a significantly longer compliance deadline. Nominally, EPA should adopt by rule an across-the-board one-year extension pursuant to § 112(i)(3)(B). However, even a four-year compliance period would be inadequate for many affected sources. Therefore, EPA should provide additional time by: (1) granting in the final rule a Presidential extension under § 112(i)(4), given that it is in the "national security interests of the United States" to prevent widespread noncompliance in the industrial base; (2) declaring that the statutory three-year compliance period is impossible to meet or otherwise produces "absurd results," which as demonstrated in EPA's recent PSD Tailoring Rule are doctrines that allow EPA to depart from clear statutory directives in appropriate circumstances; and/or (3) establishing phased or sequenced requirements such that certain element of the rule become effective no later than three years after promulgation (thus satisfying § 112(i)(3)(A)), while others are phased in at later times.

Document Control Number: EPA-HQ-OAR-2002-0058-2845.1
Comment Excerpt Number: 45

Comment: EPA proposes to set the compliance deadline for existing affected sources at three years after the date of publication of the Final Rule in the Federal Register. It will be extraordinarily difficult – if not impossible – for all of the entities with existing boilers to make the changes necessary to comply with this rule in the three year timeframe that EPA proposes. Put simply, the normally herculean task of performing a boiler retrofit in three years will be made impossible by the enormous competition for critical resources and the likely gridlock in many state permitting processes that the broad application of this rule will create. Many boiler owners will be simply unable to secure equipment and assistance and/or to obtain the state/local permits needed to retrofit their units within three years.

Even under the best of circumstances, a major retrofit of a boiler takes years from project start to finish. EPA has estimated that the installation of an activated carbon injection control system on one combustion unit – a comparatively simple installation – takes about 15 months. [Footnote: EPA, Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies (2002).] However, EPA expects a range of control devices will be used to meet the standards, including fabric filters, carbon bed adsorbers, activated carbon injection, electrostatic precipitators, wet scrubbers, replacement burners, and combustion controls.

[Footnote: EPA, Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters, 3-1 (April 2010) ("The control analysis considered fabric filters, carbon bed adsorbers, and activated carbon injection to be the primary control devices for mercury control, electrostatic precipitators for units meeting mercury limits but requiring additional control to meet the PM limits, wet scrubbers to meet the HCl limits, tune-ups, replacement burners, and combustion controls for CO and organic HAP control, and carbon injection for dioxin/furan control.")] Further, the sheer number of boilers impacted by the rule will make finding – and then scheduling – the design and construction resources almost impossible. EPA estimates that there are approximately 13,555 units located at 1,608 facilities covered by this rule. 75 Fed. Reg. 32048. Given that EPA has set emissions standards that no existing unit can meet, every single existing unit subject to an emission standard may need to be retrofitted. Boiler owners will need to hire consultants to assist them in designing and performing the retrofit. Thus, across the multitude of industries impacted by this rule, boiler owners will be competing for qualified consultants to design, permit and perform the retrofits necessary to make boilers compliant with this stringent rule. There are only a limited handful of consulting companies with the expertise to assist in such retrofits, and they will likely be unable to assist all of the boiler owners in less than three years. There will be a similar scarcity in equipment vendors, construction contractors, construction equipment (e.g, heavy lifting cranes), skilled labor (e.g., boilermakers), and other critical suppliers. Companies may even be unable to secure the basic building materials and control equipment (e.g., baghouses and scrubbers).

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Commenter Name: Alicia Oman

Comment: EPA should extend the compliance deadline given the breadth of sources and competition for resources.

In order to retrofit a boiler, the owner will need to line up the capital necessary to pay for the retrofit. In these difficult economic times, just securing the necessary capital may take months, if not years. In addition, the owner will need to go though the relevant permitting process(es), which will similarly take months, if not years. Finally, once the finances are secure and the permitting is complete, the owner will actually need to perform the retrofit. The design, procurement, installation, and shakedown of a retrofit project (e.g., installing a scrubber on a large boiler) can easily take more than three years.

In addition, the timing of the retrofit work needs to be carefully planned, particularly for boilers that provide the primary and/or base load energy supply for their facilities. A facility owner will only shut down a boiler when everything is properly staged to ensure minimal disruption of the facility's operation. In addition to ensuring that the design work is completed and the control equipment and other supplies are on-site and ready for installation, the facility owner needs to make sure that the full suite of consultants and laborers are available for the installation. Based on a discussions with a number of potentially affected companies, the turnaround or shutdown cycles for boilers at many of the facilities is so long as to make this type of precise staging exceedingly difficult to do in a three year period without substantial business interruption.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: In many instances, the installation of pollution control equipment and associated charges to boiler must be permitted under state air pollution statutes and/or construction codes (building permits, etc.). The proposed rule will result in an increase in the number of permit applications, potentially swamping the state and local agencies. Even in those areas where the rule may not result in significant increases in permitting work, the normal delays associated with permitting may make meeting the three year compliance deadline impossible.

In light of the difficulty in meeting a three year compliance deadline, EPA and authorized states should be prepared to readily grant one-year extensions under CAA 112(i)(3)(B) to those units that have problems installing the necessary control equipment to comply with the industrial Boiler MACT rule.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment: EPA should establish an extended two-step compliance period for situations where a boiler owner voluntarily elects to replace or retrofit a boiler to burn a cleaner fuel source. [Footnote: EPA recognizes the MACT rule should be crafted to encourage the use of cleaner fuels, such as natural gas. 75 Fed. Reg. 32025.] If a facility decides to switch to a cleaner fuel, the replacement or retrofit work required to make that switch will potentially take years, for all of the reasons discussed above. Rather than require the facility to add emissions controls to its existing boiler in time for the proposed three year compliance deadline – likely eliminating the possibility that the facility would switch to a cleaner fuel source – EPA should allow six years total for facilities to change their boilers and meet the MACT requirements for the cleaner fuel source. This six year period would occur in two steps; a no-backsliding provision would apply for three years from publication of the rule in the Federal Register, and then the facility would have three years to comply with MACT standard for the subcategory for the cleaner fuel subcatetory. EPA promulgated exactly this type of extended MACT compliance deadline for certain facilities that voluntarily elected to install new technology as part of the Pulp and Paper Cluster Rule. See Pulp and Paper Cluster Rule, 60 Fed. Reg. 18503, 18,508 (Apr. 15, 1998). [Footnote: This two-step approach for the MACT standard is consistent with the D.C. Circuit's decision in NRDC v. EPA, 89 F.3d 1364 (D.C. Cir. 2007) (finding invalid EPA's decision to extend the compliance deadline for a promulgated MACT rule by a year because of the substantial changes that the agency made to the rule). Rather than functioning as an extension of the compliance deadline, this MACT standard for certain facilities would become applicable in two steps. For the first three years, a no-backsliding MACT standard would be applicable, then the three year deadline to implement the MACT standard for the applicable “cleaner” source would begin to run.] In addition to providing an incentive for facilities to switch to cleaner fuel sources, this approach would reduce some of the competition for resources discussed above by extending the deadline to complete the work to replace or retrofit certain boilers.

Comment: EPA SHOULD ALLOW A LONGER COMPLIANCE TIMEFRAME. EPA proposes to set the compliance deadline for existing affected sources at three years after the date of publication of the Final Rule in the Federal Register. It will be extraordinarily difficult – if not impossible – for all of the entities with existing boilers to make the changes necessary to comply with this rule in the three year timeframe that EPA proposes. Put simply, the normally herculean task of performing a boiler retrofit in three years will be made impossible by the enormous competition for critical resources and the likely gridlock in many state permitting processes that the broad application of this rule will create. Many boiler owners will be simply unable to secure equipment and assistance and/or to obtain the state/local permits needed to retrofit their units within three years.

Even under the best of circumstances, a major retrofit of a boiler takes years from project start to finish. EPA has estimated that the installation of an activated carbon injection control system on one combustion unit – a comparatively simple installation – takes about 15 months. [EPA, Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies (2002).] However, EPA expects a range of control devices will be used to meet the standards, including fabric filters, activated carbon injection, electrostatic precipitators, wet scrubbers, replacement burners, and combustion controls. [EPA, Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters, 3-1 (April 2010) ("The control analysis considered fabric filters, carbon bed adsorbers, and activated carbon injection to be the primary control devices for mercury control, electrostatic precipitators for units meeting mercury limits but requiring additional control to meet the PM limits, wet scrubbers to meet the HCl limits, tune-ups, replacement burners, and combustion controls for CO and organic HAP control, and carbon injection for dioxin/furan control.")] Further, the sheer number of boilers impacted by the rule will make finding – and then scheduling – the design and construction resources almost impossible. EPA estimates that there are approximately 13,555 units located at 1,608 facilities covered by this rule.[75 Fed. Reg. at 32048.]

Given that EPA has set emissions standards that only a handful of existing units can currently meet, almost every single existing unit subject to an emission standard will need to be retrofitted. Boiler owners will need to hire consultants to assist them in designing and performing the retrofit. Thus, across the multitude of industries impacted by this rule, boiler owners will be scrambling to find the very few qualified consultants who can perform the retrofits necessary to make boilers compliant with this stringent rule. There are a limited number of consulting companies with the expertise to assist in such retrofits, and they will likely be unable to assist all of the boiler owners in less than three years, especially when the electric utility industry will be competing for the same resources in order to comply with their own MACT standard. There will be a similar scarcity in equipment vendors, construction contractors, construction equipment (e.g., heavy lifting cranes), skilled labor (e.g., boilermakers), and other critical suppliers. Companies may even be unable to secure the basic building materials and control equipment (e.g., baghouses and scrubbers).

In order to retrofit a boiler, the owner will need to line up the capital necessary to pay for the retrofit. In these difficult economic times, just securing the necessary capital may take months, if not years, assuming the capital can be obtained from lending sources. In addition, the owner will need to go though the relevant permitting process(es), which will similarly take months, if not years. Finally, once the finances are secure and the permitting is complete, the owner will actually need to perform the retrofit. The design, procurement, installation, and shakedown of a retrofit project (e.g., installing a scrubber on a large boiler) can easily take more than three years.

An example of a rulemaking that involved control retrofits over an extended compliance period is the implementation of the 1-hour ozone SIP requirements in Houston, Galveston, and Brazoria Counties in Texas. Due to the magnitude of the NOx emissions reductions required and the number of sources affected, emission reduction projects were implemented over a 6-year timeframe (2001-2007), with a total capital investment of over $3 billion. As the Boiler MACT will involve more significant emission controls retrofits, it is appropriate to allocate a longer compliance timeframe.

In addition, the timing of the retrofit work needs to be carefully planned, particularly for boilers that provide the primary and/or base load energy supply for their facilities. A facility owner will only shut down a boiler when everything is properly staged to ensure minimal disruption of the facility's operation. In addition to ensuring that the design work is completed and the control equipment and other supplies are on-site and ready for installation, the facility owner needs to make sure that the full suite of consultants and laborers are available for the installation. Based on discussions with a number of potentially affected companies, the turnaround or shutdown cycles for boilers and process heaters at many of the facilities can vary from 1 to 5 years, making this type of precise staging exceedingly difficult to do in a three year period without substantial business interruption.

Comment Excerpt Number: 235

Comment: Alternatively, in light of the significant challenges presented by the breadth and number of boilers in the source category, which are discussed above, EPA, the Department of Energy and the Department of Commerce should prevail upon the President to exempt sources from compliance with the standards for a period of not more than 2 years based on a determination that the technology to implement the standards is not available and it is in the national security interests of the United States to do so. As discussion elsewhere in these comments makes clear, the control technology that would allow boilers to meet the proposed stringent suite of standards simply does not exist. Further, even if the agencies determine that such control technology exists, it will not be "available" for most boilers because of the resource limitations discussed above. Granting an extension under section 112(i)(4) is in the national security interests of the United States in order to avoid the widespread shutdown of non-retrofitted boilers that a three year compliance deadline would demand. The boilers impacted by this rule power almost every sector of the United States economy, including sectors that provide critical supplies to the nation’s security infrastructure.

Comment: Extend the Compliance Deadline.
The three year compliance deadline must be extended for existing sources. It is unreasonable to expect that all of the sources that must retrofit can accomplish the necessary testing, systems design and engineering and equipment production when thousands of facilities are seeking these services. Section 112(i)(4) provides the legal basis for an extended compliance period.

Response: Regarding the commenter's concerns on a reasonable implementation schedule, see response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 218.

Comment Excerpt Number: 12

Comment: The regulation needs to be clarified that any increases in NOx emissions as a result of the annual boiler tune-up to minimize CO emissions will not be a violation of existing permit conditions.

Response: The tune-up requirement should not result in substantial increases in NOx because sources are only required to tune the boiler to manufacturer's specifications. NOx emissions become higher when the boiler combustion is adjusted (tuned) to lower CO levels than those for which the boiler was designed (manufacturer's specification) to operate. Further, we have modified the language in the tune-up from "minimize" CO to "optimize" CO in order to consider the trade-off between NOx and CO emissions, and the focus of many state boiler tune-up programs which focus on minimizing NOx emissions, while optimizing combustion efficiency.

Comment: Fuel switching – NSR penalty
New Source Review is an unintended consequence of switching to a cleaner fuel. One of the Boiler MACT responses available to the University is fuel switching to natural gas. The University currently combusts 2 trillion Btu’s a year . Of that total,
97% is from the combustion of bituminous coal and the remaining 3% is from the combustion of natural gas. Should the University switch to firing all natural gas, the Pennsylvania Department of Environmental Protection (DEP) has determined that an
NSR applicability determination will be done comparing past natural gas to future natural gas. This determination will certainly trigger NNSR for NOx, and PSD for CO. The University believes this to be an unintended negative consequence. It
seems incongruous that taking an action that will result in significant decreases in emission, will result in this stringent a permit review. Based on past stack tests, the decrease in emissions in

tons per year, will be: carbon monoxide = 140, nitrogen oxides = 235, sulfur oxides = 1920, HCl = 237, and carbon dioxide = 73,300. The per cent decrease for each of these pollutants will be: 65%, 63%, 99.9%, 100%, and 40% respectively. Penn State suggests that EPA address this in the guidance documents to
state agencies, specifically that the decision on NSR applicability is on a source by source basis and not on a fuel by fuel basis.

Response: EPA acknowledges the concerns of the commenter. A final response on guidance provided to state agencies on NSR applicability as it relates to requirements of this rule are outside the scope of this comment response document.

Comment: In the previous Boiler MACT and all other Boiler regulations there is a slight but significant difference in the group sizing.
All previous regulations grouped by: Boilers 100 MMBtu/hr; Boilers > 100 MMBtu/hr; and < 250 MMBtu/hr; Boilers > 250 MMBtu/hr

The proposed Boiler MACT grouped by: Boilers < 100 MMBtu/hr;Boilers 100 MMBtu/hr and < 250 MMBtu/hr; Boilers 250 MMBtu/hr

Why has the EPA adjusted the range for the size categories? It is requested that the Boiler MACT size classification be changed to reflect all other boiler regulations.

Response: In the final rule, the size threshold of 100 mmBtu/hr is no longer relevant since there are no CO CEMS requirements in the final rule. We have modified the threshold of 250 mmBtu/hr to be greater than 250 mmBtu/hr instead of greater than or equal to 250 mmBtu/hr in order to be consistent with the size thresholds in the New Source Performance Standards for Industrial/Commercial/Institutional boilers and process heaters (40 CFR part 60 subpart Db).

Comment: In section 63.7525(a), Performance Specification 4A is required for CO CEMS. This performance specification was primarily developed for CEMS intended to demonstrate compliance with CO emission standards less than 200 ppmv. As the proposed rule includes CO limits for some units that are greater than 200 ppmv, EPA should also allow the use of Performance Specification 4, which was designed for CO span values in the 1000 ppmv range.

Response: A CO CEMS is no longer a requirement in the final rule and we have removed discussion of PS 4A from the rule language.

Comment Excerpt Number: 2

Comment: These suggested limits will be near impossible to achieve without installation of additional pollution controls, i.e., above controls already mandated by current regulation. Units with current pollution controls not meeting these standards will be required to retrofit, replace, or either install additional controls. In short, this proposed rule potentially suggests compliance can be achieved by installing additional end-of-pipe controls on the end of existing end-of-pipe controls.

The estimated const for retrofitting, replacing, or installing additional controls in existing biomass boilers to meet these proposed standards falls between $10 million and $20 million per boiler. This enormous cost would divert valuable dollars to fund a program having little to no real human health or environmental benefits.

Response: See preamble for response.

Commenter Name: Norbord Industries
Commenter Affiliation: Norbord Industries
Document Control Number: EPA-HQ-OAR-2002-0058-0854.1
Comment Excerpt Number: 5

Comment: Reviewing the emission standards and potential emission control equipment for HCl and particulate, Norbord became aware that it's current ESP system at some facilities would likely not be able to comply with the PM standard if the need to control HCl (most likely lime injection) becomes necessary. Control technologies for HCl would add quite a bit of particulate loading to the system not to mention the likelihood a wet system will likely be required as well to bring the HCl levels to the extremely low standard set. This would require that the ESPs be removed for a system capable of handling high moisture levels or a lime injection system installed after the ESP along with additional PM controls. This is not even taking into consideration the potential need to control mercury and dioxins/furans.

Additionally, it appears EPA did not take into consideration the costs associated with the need to radically change current control systems, burners and even fuels. Norbord is aware that other entities will be providing more specific cost data, but EPA should take the cost of this rule much more seriously. Did EPA take into consideration the cost requirements to comply with other MACT standards as well? Did EPA take into consideration the havoc it's creating with all the different scenarios needed to comply with such an overly strict rule? In at least the wood products industry many mills are spending more than a million dollars a year on gas costs for HAP reduction. Many of these facilities were forced to close in recent years and many more will close if this rule is not changed.

Comment: TRM asked a consultant for a preliminary cost estimate to achieve compliance to the new rules. An ESP, catalytic oxidizer, a wet scrubber, a bag house, major duct work, and permitting would be required for each boiler. The estimated cost for both boilers -- $6 million to $12 million! This does not include the increased ongoing operating costs. The consultant is concerned that even at this exorbitant cost, compliance may not be achieved.

Response: See response for DCN EPA-HQ-OAR-2002-0058-1779, Excerpt Number 78.

Comment Excerpt Number: 3

Comment: While I'm not ready to discuss specific
cost projections for my facility, the figures for the
forest product industry in Mississippi are indicative.
In Philadelphia, we would need to consider adding on at
least three control devices to address at least four of
the five hazardous air pollutants that EPA has proposed to strengthen and regulate on the Boiler MACT group, and
we would have to do so not knowing whether the controls
with extremely low levels of pollutants such as mercury
and dioxides would be effective or could even be
measured with certain. There's got to be a better way.
What we'd like EPA to do with the cost impacts for the
rules that are proposed so large, and numerous technical

issues that others will detail, we urge EPA to make this
a win-win and use its discretion and improve the rules
significantly to reduce the compliance cost.

Response: See preamble for response.

Comment Excerpt Number: 16

Comment: Since the proposed emission limits are unachievable simultaneously and at all operating conditions while meeting applicable NOx limits without add-on controls, all gas and liquid units subject to emission limits will have to install CO controls, rather than just some units as EPA assumed. Many, in addition to those identified in the Agency estimates, will also have to install PM, Hg and HCl controls to handle normal variability, since those limits apply at all times. For the limited number of units that may be able to meet the proposed CO limits at all times without oxidation catalyst, SCR controls for NOx will often be needed because low-CO operating conditions greatly increase NOx production. In these cases, costs and burdens reflecting increased energy consumption and increased CO_2 emissions must also be included in the estimates.

A significant percent of units will be unable to add controls to the existing unit because of space or structural constraints and thus replacement units will need to be constructed at greatly increased cost. The RIA estimates included no costs or burdens for replacement units or for installing CO controls on most Gas 2 and liquid fired units. Additionally, no costs were included for lost production while the boiler or process heater was being replaced or for the costs associated with such replacement units having to meet new source standards rather than existing source standards.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2698.1, Excerpt Number 14.

Comment: It is unclear from our preliminary review of the EPA cost analyses that process heaters were appropriately handled. Process heaters are not boilers and estimates based on boiler information are incorrect. If, in fact, the process heater cost estimates were scaled from estimates for adding controls to boilers, the process heater costs are likely to be grossly underestimated.

Response: See preamble for response.

Comment: A lot of the speakers talk about biomass. We recently

had a large biomass plant apply to our energy commission here in California for permits. And their estimated emissions limits were higher than if they were going to burn coal.
And actually there was a major report released yesterday on biomass burning and how many of the states back east are meeting their portfolio standards by cutting down their forests and burning wood. So the whole concept of biomass burning and whether it’s really a good idea or not bears some scrutiny.

Response: Whether or not biomass burning is a good idea is outside the scope of this rulemaking.

Comment: Where these costs are unsupportable or where the emission limits still could not be met, units and processes would have to shutdown to avoid non-compliance, with resulting economic and job loss.

The costs for such replacements and the full extent of controls were not considered in the cost and burden analyses for Gas 2 sources or for the alternate Gas 1 proposal presented to OMB for review or in the rulemaking record and the impact of shutting down processes and job loss were not addressed. It is our opinion that it cannot have been Congress's intent for EPA to set emission limits without regard to feasibility or their impact on the sources being regulated or the impact on the economy in general. Consideration of the actual costs and burdens and the economic impacts of imposing emission limits on gas-fired boilers and process heaters further supports the conclusion that applying emission limitations to Gas 1 units is infeasible and demonstrates that that same conclusion should be reached for Gas 2 units.

Comment: Inspection of the estimate details supports our belief of a significant undercounting. For instance, the proposal RIA4 reports there are 199 existing units nationally that fire Gas 2 (gases other than natural gas and refinery gas). This is clearly an unreasonably low number. Our members alone account for more than 180 boilers and process heaters in Gas 2 service at major sources. Since the RIA estimates, in Table 3-1, annualized O&M costs of $500 million per year for just these 199 units, the national impact of underestimating their number is clear.

Response: EPA has adjusted its definition of gas 2 units and the revised estimates were adjusted downward to consider the revised definition. EPA also incorporated new data received on other units that were not previously included in the inventory for major source boilers and process heaters.

Comment: This regulation will require us to install additional particulate (PM) control devices and continuous opacity monitors as well as to perform Energy Assessments and annual stack and fuel testing on both of our boilers. It could not come at a worse time! With a compliance date of 3 years from final approval of this regulation, we find ourselves in the middle of a crippling economic downturn where many industries are moving off-shore. We are struggling to stay in business as it is.

Emissions Standards:
Current Boiler Emissions = 0.135 lb PM/mmBTU.
The proposed limit for existing Boilers = 0.02 lb PM/mmBTU!
The proposed limit for new Boilers = 0.008 lb PM/mmBTU!
We will also have limits for CO, Hg, HCL, Dioxin / Furan for which we have no idea if we will be compliant or non-compliant.

Attaining the new particulate matter (PM) limit will require $500,000 to $1,000,000 to replace the existing multiclones on our two boilers with baghouses or electrostatic precipitators. Plus, either control device will require extensive, on-going maintenance that will be very expensive. We simply cannot afford such expenditures at this time. Further, the end result will not afford any increase in production throughput and will have minimal impact on our air quality!

Comment: Cost per ton of HAP's Controlled for Biomass Units

Using the data provided in the preamble Tables 10 and 11, the cost per ton of HAP's controlled for the biomass units is significantly higher than the coal-fired and liquid-fired units. HAP's controlled do not include PM.

Biomass $403,258 per ton
Coal $44,094 per ton
Liquid $125,826 per ton

The relatively poor cost-effectiveness for the biomass subcategories in controlling HAP's under the proposed rules provides a strong disincentive to use biomass fuels. This should not be the case given the inherently low emissions of HAPfs and GHG's associated with biomass fuels.

Comment Excerpt Number: 270

Comment: EPA does not appear to have considered this constraint on availability of control technology for meeting HCl limits at wood products facilities. A wet scrubber or wet ESP may be the only reasonable approach to reducing emissions of particulate and other pollutants regulated by the proposed Boiler MACT and CISWI standards as well. The use of a scrubber or wet electrostatic precipitator on a large boiler at a wood products facility may require the discharge of at least 10 gallons per minute of blowdown (14,400 gallons per day). For facilities subject to a prohibition on wastewater discharge, this control technology would be unavailable as a practical matter. (Additional information about wastewater from pollution control equipment at wood products facilities (in that case, primarily associated with VOC controls) and the difficulties of handling additional wastewater at wood products facilities can be found in AF&PA's March 7, 2003 comments on the proposed Plywood & Composite Wood Products NESHAPS, EPA OAQPS Docket No. A-98-44, Item IV-D-7, which we ask be incorporated by reference in the administrative record for the Boiler MACT rulemaking.)

EPA recognized this same problem when it established MACT standards for the Plywood and Composite Wood Products category. As part of the final MACT standards, EPA amended the definition of "process wastewater" in the Timber Products Processing effluent guidelines to exclude wastewater generated by the types of air pollution control equipment EPA had identified as the basis of MACT standards for those source categories subject to a zero discharge effluent guidelines. See 40 C.F.R. § 429.11(c); 69 Fed. Reg. 45,944 at 45,964 (recognizing that wood products facilities could not meet the zero discharge requirement after complying with the Plywood and Composite Wood Products NESHAPs, "because of the volume of wastewater generated by APCD that are installed to comply with the final PCWP NESHAP and because the technology basis for those effluent limitations guidelines and standards is insufficient, in light of that wastewater volume and the pollutant content, to achieve the prohibition on process wastewater discharges for these NESHAP-related APCD wastewaters").

Comment: The Chester, CA plant consists of a sawmill and biomass co-generation power plant that produces 12 MW of electricity. The steam also fires the lumber dry kilns and provides plant heating. This plant provides 108 union (Carpenters & Jointers) family wage jobs and is the largest employer in this small rural Sierra Nevada community. Replacement cost of a boiler with no guarantee of meeting the proposed standards would be approximately $20 million. This facility in 2009 had a payroll of$5.9 million, with $1.8 million in employee related taxes and $606 thousand in local property taxes.

In Lakeview, OR we operate a sawmill with a wood fired boiler that produces steam for the dry kilns and plant heating. This facility employs 76 people with family wage jobs and is the largest private employer in this small rural Eastern Oregon town located 95 miles from the nearest regional shopping and medical facilities. A replacement boiler with no guarantee of meeting the proposed standards would be approximately $ I0 million. The Lakeview facility in 2009 had a payroll of $3 million, with $900 thousand in employee related taxes and paid $110 thousand in local property taxes.

Our Kane, PA facility is a hardwood sawmill and dimension plant that utilizes a wood fired boiler for dry kilns and plant heating. We employ 99 people with family wage jobs and this is the largest private employer in this small rural Northern Appalachian town. A replacement boiler with no guarantee of meeting the proposed standards would run approximately $10 million. The Kane facility had a 2009 payroll of $3.7 million, with $1.1 million of employee related taxes and paid $593 thousand in local property taxes.

Keep in mind that due to the current recession and housing crisis, these plants ran at a one shift reduced basis. In normal times we’d operate at a higher production level with the attendant increase in employment and payroll.

Comment Excerpt Number: 6

Comment: In addition to smaller natural gas-fired boilers/process heaters, EPA is proposing work practices for natural gas-fired boilers/process heaters with a heat input capacity over 10 mmBtu/hour given that the cost of installing controls to comply with emission limits for the five HAP groups is over $14 billion. This number grossly underestimates the cost of add-on controls by excluding the monitoring and operating expenses associated with such equipment. Other industry groups filing comments on this proposal have estimated that the cost of add-on controls for natural gas-fired units in EPA's database alone would be upwards of $51 billion for the subcategory. In reality, this number is likely even higher given that EPA's database does not include all the natural gas units in the country that would be affected by this rule.

Comment Excerpt Number: 7

Comment: In this rulemaking, EPA has followed the costing assumptions and techniques in the OAQPS Control Cost Manual (EPA 452/B-02-001). AF&PA continues to believe this approach underestimates the total installed cost of air pollution control equipment, as discussed in previous AF&PA comments submitted on various other proposed emission standards. The Control Cost Manual has not been updated in many years, does not reflect the current costs, and is missing information on several control technologies. While it is recognized EPA is not obligated to consider costs of MACT emission standards when the standards are set at the so-called MACT floor level, AF&PA feels EPA has grossly understated the capital and annualized costs of this proposed rule.
Because of the anticipated major financial impact of this rule on the forest products industry, AF&PA has also estimated the capital costs for installation of additional control technologies on existing boilers. AF&PA did not consider potential cost reductions that might result from emissions averaging, health-based emission limits, or an alternative metals limit in the final rule and we assumed that the Gas 1 emission limits discussed in the preamble would not be promulgated.
We developed a detailed spreadsheet to estimate costs for Boiler MACT, based on EPA's major source boiler inventory database table. Because the proposed rule does not include emission limits for natural gas boilers or boilers less than 10 MMBtu/hr heat input, these units were not included in the cost analysis. Based on the information in the EPA emissions database on boiler size, fuel, existing controls, and emissions, we estimated costs of controls that would likely be necessary to comply with the Boiler MACT for coal, biomass, liquid, and gas 2 boilers. As some forest products boilers at major sources did not receive an ICR from EPA in 2008, we added information for those boilers to the detailed spreadsheet based on a database maintained by Fisher International and information from NCASI. We also estimated costs for a few boilers that

were in the CISWI database but will no longer burn fuels likely to be designated as waste under EPA's proposed approach to defining non-hazardous secondary materials.
Information from various sources [Footnote: See for example "Evaluation of Air Pollution Control Costs for the Pulp and Paper Industry," May 1, 2003, prepared by Stone and Webster Management Consultants for National Economic Research Associates (NERA) and included in Appendix E to these comments.] was used to determine a base capital cost for a 250 MMBtu/hr boiler for each PM and HCl control technology option and then scaled using a 0.6 power function based on the size of each boiler in the inventory. For example, the capital cost of a wet scrubber on a 100 MMBtu/hr boiler is calculated as the base cost times (100/250)0.6. A fixed capital cost of $1 million was assumed for installation of a carbon adsorption system for Hg and/or dioxin control, as these systems do not vary much in cost by boiler size. A fixed capital cost of $2 million was assumed for CO controls (either projects to improve combustion or fuel feed or installation of a CO catalyst). Base cost assumptions are presented in the report contained in Appendix D. It should be noted that the goal was not to create a worst-case cost estimate for each boiler. Rather, the cost estimates represent median costs for the various control scenarios based on published reports, industry and vendor information on specific project costs, EPA reports or control device fact sheets, or actual BACT or BART analyses previously submitted to permitting agencies.
To estimate capital costs for each boiler, we assumed that if there was no emissions information available for a particular boiler, the unit would likely need MACT, which EPA stated in the preamble to the proposed Boiler MACT is a fabric filter (FF) plus carbon injection plus wet scrubber plus combustion improvements (or CO catalyst). For PM, if a unit did not already have a FF or ESP and there was information that indicated the unit cannot meet the proposed limit or there was no emissions information, we assumed a new FF. If the unit already had a FF or ESP and there was information that indicated the unit cannot meet the proposed limit we assumed an upgrade to the existing control equipment. To estimate control costs for HCl, if there was information that indicated the unit cannot meet the proposed limit or if there was no emissions information, we assumed either a scrubber upgrade or new scrubber depending on whether the unit currently had a scrubber. For Hg and dioxin, if there was information that indicated the unit cannot meet the proposed limit or if there was no emissions information, we added carbon injection. For CO, if there was information that indicated the unit cannot meet the proposed limit and is not a fluidized bed boiler, stoker boiler, suspension boiler, or Dutch oven, then we assumed that capital would be necessary to either perform combustion and/or fuel feed improvements or other boiler improvement projects to reduce CO or install a CO catalyst.
Although EPA's estimates indicate that the total capital cost will be $9.5 billion, AF&PA has estimated that the total capital cost of the rule will be over $20 billion for industry, with $6 billion in costs for the forest products industry alone. It is evident major capital investments in add-on control technology will be required for continued operation of solid and liquid fueled boilers at pulp and paper mills and wood products plants.

While the above estimate appears very high compared to the EPA estimate, we believe this estimate to actually be very conservative, since our methodology assumed that controls could actually be installed in a manner that they would achieve the emission levels proposed by EPA overall operating scenarios, including startup and shutdown.

Comment: In reality, many units will simply not be able to be retrofit with controls and/or will not be able to meet the emissions limits regardless of controls, so that total combustion unit replacement would be required, which would greatly expand the cost of the rule for individual facilities. That inability to retrofit or meet the emission limits will undoubtedly result in shutdown of marginal production facilities with a loss of jobs and collateral negative economic impact at all social levels. We believe that EPA has failed to consider this highly likely impact since they have simply not considered achievability of the emission limits they are proposing. Without this consideration, the true cost and collateral impacts of the rule are not identified and, therefore, cannot be considered relative to legitimacy of the rulemaking.

Comment: EPA used a catalyst cost of $959.25 per cubic foot from Chapter 2 of the OAQPS Control Cost Manual, according to Table 1 of the ERG cost methodology memo. We assume this means Section 3, Chapter 2, VOC Destruction Controls, dated 2002. Page 2-45 indicates that this cost is based on a 1998 estimate of $650/cubic foot, and we assume that ERG scaled this estimate up to 2008 dollars. Based on a May 2009 cost estimate obtained from BASF by URS Corporation for use in a BACT cost estimate for a CO catalyst on a forest products industry boiler, BASF estimated a cost of $4000 per cubic foot for catalyst modules and supports. As EPA has information from BASF in the docket for this rulemaking, EPA should also have confirmed their cost estimating techniques for CO catalyst installations rather than using outdated cost methodology applicable to catalytic oxidizers for VOC control, which are of different design than a CO catalyst system. EPA should update its CO catalyst costs.

Comment: We do not agree with the methodology used to determine the cost of CO emissions reductions for boilers with CO emissions less than 400 ppm at 3% O2. The ERG cost and emissions impacts memo states that the cost of a tune-up was estimated if the unit's baseline emissions exceeded the floor for CO but were less than or equal to 400 ppm at 3% O2. Based on conversations with boiler and burner vendors, there are certain boiler and burner designs that cannot achieve the proposed emission limits with a simple tune-up, especially in cases where a low NOx limit must simultaneously be achieved or where biomass is being burned with coal. For combination coal/biomass stoker boilers to achieve the proposed 50 ppm CO limit, it will take more than a tune-up; it will likely take more expensive fuel feed and/or combustion improvements. For many liquid and gas boilers to achieve a 1 ppm CO limit, it will take more than a tune-up; these boilers with low NOx limits will likely face installation of a CO catalyst, which has not been proven to achieve the proposed emission levels or provide an associated reduction in organic HAP emissions. The ability to retrofit CO catalyst systems on all types of existing boilers and process heaters and the effectiveness of these systems in reducing organic HAP emissions are major concerns that need to be addressed by EPA. EPA should re-evaluate its assumptions with respect to feasible options for reductions in CO emissions.
* We do not agree with the methodology used to determine the cost of CO emissions reductions for stoker, fuel cell, and fluidized bed boilers with CO emissions between 400 and 1000 ppm at

3% O2. The ERG cost and emissions impacts memo states that since these boilers do not have replaceable burners, the cost of a linkageless boiler management system (LBMS) was estimated to achieve the MACT floor. An LBMS is not going to be sufficient for a coal/biomass stoker boiler with CO emissions between 400 and 1000 ppm at 3% O2 to achieve 50 ppm CO; it will require the installation of a new overfire air system at a minimum (and possibly a CO catalyst) in order to reduce CO emissions from co-firing coal and biomass to below 50 ppm. Comments on the ability of combination coal/biomass boilers to meet the proposed coal CO emission limits are presented later in this document. Again, EPA should re-evaluate its assumptions with respect to feasible options for reductions in CO emissions.
* We have estimated the cost for CO emissions controls for boilers in the coal and biomass subcategories of $1.2 billion, compared to EPA's cost estimate for the entire rule for CO control of $13.9 million.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 117.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 18

Comment: We do not agree with the methodology used to determine the cost of CO emissions reductions for liquid and gas-fired boilers. The ERG cost and emissions impacts memo states that if baseline CO emissions were between 400 and 1000 ppm for boilers and process heaters designed to burn liquid and gaseous fuels, the cost of a low-NOx burner was estimated to achieve the MACT floor emission limits. The CO limits for these boilers in the proposed rule are 1 ppm. Based on conversations with burner vendors, a low-NOx burner is typically guaranteed to produce CO emissions of 50 to 100 ppm for gas and liquid boilers. EPA's assumption that a burner retrofit will result in achieving the proposed single digit emission limits is simply unfounded. EPA should re-evaluate its assumptions with respect to feasible options for reductions in CO emissions.
* We have estimated the cost for CO emissions controls for boilers in the liquid and gas 2 subcategories of $1.5 billion (assuming controls will achieve 1 ppm CO for all boilers under all operating conditions), compared to EPA's cost estimate for the entire rule for CO control of $13.9 million.
* EPA's cost estimates for CO controls assume that tune-ups and LBMS will achieve very high CO reductions. This assumption is false and is indicative of a lack of recognition of how industrial systems are operated. Much of industry has been operating under extreme financial constraints and lowering costs has been a high priority for a long time. Many combustion units are routinely operated at optimum efficiency so that there is no further opportunity for combustion efficiency adjustment. In fact, EPA's proposed approach to tune-ups (the focus on minimizing CO emissions) will actually in most cases result in use of increased excess air and lead to decreased efficiency and increased emissions overall, counter to EPA's assumption of a 1% efficiency improvement with tune-ups. In the case of biomass boilers, we believe that improvements to fuel feed and combustion air systems that will cost more than the costs

estimated for tune-ups and LBMS are more likely to be required in order to improve the performance of these boilers enough to meet the proposed limits. Addition of overfire air to a large biomass boiler can be at least $500,000. EPA's total estimated capital cost of $13.9 million for combustion controls and oxidation catalysts presented in Table 2 of the cost and emissions impacts memo is extremely low and a gross underestimate of the actual costs that industry boilers will incur to comply with the CO limits in the rule. The liquid and gas 2 limits of 1 ppm in particular will impose extremely high costs for control on some units. EPA should re-evaluate their assumptions with respect to the effect of tune-ups on emission levels and fuel use.

Comment: EPA has estimated that activated carbon injection will only be required on 155 existing boilers because installation of a fabric filter is expected to achieve the mercury emission limits, except in cases where a unit already has a fabric filter and does not meet the limits. We do not agree that fabric filters will be sufficient to reduce mercury emissions to the ultra low levels proposed in this rule in all cases. There are flaws in EPA's logic that fabric filters are expected to achieve mercury emission limits. First, there are many boilers in the database that are equipped with fabric filters and have measured mercury emissions higher than the proposed limits. Second, when burning fuels containing mercury with fuels containing sulfur (e.g., biomass with TDF, oil, or coal), mercuric sulfate is formed, which is a particulate and can be captured in a fabric filter, but when fuels such as biomass and natural gas with low mercury contents are burned without sulfur-containing fuels, elemental mercury is the primary emission and is not captured in a fabric filter. EPA's estimated industry-wide capital cost for activated carbon injection presented in Table 2 of the cost and emissions impacts memo is extremely low, at only $9.5 million. We do not understand how this can represent 155 boilers; it seems to us to represent the cost 10 boilers would incur to install a carbon injection system. AF&PA's cost estimate for mercury and dioxin/furan controls (carbon injection) is $1.7 billion. EPA should re-evaluate its cost estimates for mercury control.

Comment: Per the Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source document, EPA estimated that an ESP would be installed to meet the PM emissions limit unless a unit already had a fabric filter installed. We believe that since sorbent injection will be required for acid gas, mercury, and dioxin control, that fabric filters will likely be chosen for units without existing ESPs in order to maximize the performance of the sorbents and minimize the amount of sorbent used. For example, use of an ESP will require 4 times the carbon to be injected for mercury/dioxin control than if a fabric filter is used. Using EPA's cost algorithms, installation of a fabric filter has a higher capital cost than installation of an ESP; therefore this assumption results in an underestimate of the capital cost required to meet the proposed PM limits.

Comment: EPA has estimated costs to install packed bed scrubbers for HCl control. Industrial boilers do not use packed bed scrubbers for acid gas control, as the limitations of these devices make them impractical for use on applications with high flow rates, high PM loading, and high inlet pollutant concentration. EPA's own fact sheet on these devices, located at http://www.epa.gov/ttn/catc/dir1/fpack.pdf, lists these limitations of these devices and indicates that they are only used in applications up to 75,000 scfm, which limits their use to small units only. Facilities will instead install wet scrubbers, dry scrubbers, or semi-dry scrubbers to control acid gas emissions from industrial boilers. EPA has estimated HCl control costs for equipment that industry is not likely to install. In addition, no consideration was given for facilities that may have zero discharge permits (as many wood products facilities do), where it is infeasible to install a wet control device. EPA should re-evaluate its cost estimates for HCl control. AF&PA has estimated capital costs for HCl control of $9.3 billion, while EPA's capital cost estimate for wet scrubbers is $3.3 billion.

Comment: EPA presents several cost options in the two ERG memos. Option 2E assumes that facilities will not incur costs to comply with the dioxin/furan standards because they will test for dioxin/furan and be below detection levels. This logic does not make sense, especially because EPA has not outlined in the rule any procedures for handling non-detects when performing compliance testing and there are boilers in the EPA emissions database with dioxin/furan emissions that are non-detect but actually measured emissions higher than the proposed limit. More detailed comments on detection limit issues and the dioxin/furan emissions data are presented later in this document.

Comment: The limits being considered for Boiler MACT would necessitate combinations of emission controls that have adverse effects on each other. In other words, the presence of one control technology could prevent a second control technology from operating at optimum performance.

A primary control for Hg emissions involves the injection of activated carbon into the flue gas. The mercury is oxidized on the active sites on the carbon particles. The oxidized form of Hg can then either be recovered by the particulate control equipment, or by the scrubber (since oxidized Hg is soluble). The oxidation reactions only occur at temperatures below about 350ºF. The effectiveness of the activated carbon for oxidizing Hg is dependent upon the amount of time that the carbon has to attract the Hg to one of its active sites.

The use of activated carbon injection for Hg control is negatively affected by the presence of sulfur trioxide (SO3). SO3 occupies the active sites on the carbon, taking away those sites from the Hg. Even a few parts per million of SO3 can have a significant negative impact on the Hg removal that is achieved by activated carbon injection. Small amounts of SO3 are generated as part of the combustion process for sulfur-containing fuels, while the bulk of the sulfur in the fuel is oxidized to SO2. However, other control devices, such as CO oxidation catalyst or SCR NOx reduction catalyst, will convert an additional percentage of the SO2 to SO3, resulting in poor Hg removal.

Comment: EPA should also evaluate the data in the database to ensure that boilers can apply additional controls that will achieve the proposed limits. For example, it should examine the percent mercury and HCl reductions necessary for the boilers in a subcategory and, taking into account the fuels burned by the boiler and the controls already in place, EPA should determine if it is even feasible to further control emissions down to levels below the proposed standards.

Comment: Based on our review of the survey database, Major Source Boilers & Process Heaters Inventory Table, for UVA sources (Facility ID = VAUniversityofVirginia), we noticed that our 11 boilers over 10 MMBtu/hr heat input that are designed to burn natural gas and distillate oil are classified as gas 1 subcategory boilers. While oil may not be routinely combusted in these boilers, some fire enough oil to exceed the 10% heat input threshold in the definition of a gas 1 subcategory. At a minimum, Boilers 5575-1-01 through -04, 7103-1-03R, 7103-1-04R, 7533-1-01 and 7533-1-02 should be classified in the liquid subcategory; these boilers are at our district heating plants and we may need the operating flexibility to burn gas or oil. EPA's estimates of the compliance costs should be updated to reflect the higher compliance costs associated with existing liquid fire boilers.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2506.1, Excerpt Number 21.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 2

Comment: EPA's estimated costs of the rule are significantly lower that the real cost impact on sources. Although EPA's estimates indicate that the total capital cost of the Proposed Rule will be $9.5 billion, CIBO and URS have estimated that the total capital cost of the rule will be over $20 billion for all affected sources for installation of emissions controls on coal, liquid, and Gas 2 boilers. Major capital investments in add-on control technology will be required for continued operation of the industrial, commercial and institutional (ICI) power house and energy base of the country.

Based on EPA's major source boiler inventory database,which includes information on boiler size, fuel, existing controls, and emissions, we estimated costs of controls that would likely be necessary to comply with the Boiler MACT for coal, biomass, liquid, and Gas 2 boilers for units 10 MMBtu/hr and greater. Because the Proposed Rule does not include emission limits for natural gas boilers, these units were considered in a separate cost analysis assuming the work practice standards would not be allowed and the proposed Gas 1 limits in the preamble would be applied, requiring application of control technology to these boilers and process heaters for all regulated pollutants.

Information from various sources was used to determine a base capital cost for a 250 MMBtu/hr boiler and process heater for each PM and HCl control technology option and then scaled using an 0.6 power function based on the size of each boiler and process heater in the inventory. For example, the capital cost of a scrubber on a 100 MMBtu/hr boiler is calculated as the base cost of $8 million times (100/250)0.6. A fixed capital cost of $1 million was assumed for installation of a carbon adsorption system for Hg and/or dioxin control, as these systems do not vary much in cost by boiler size. A fixed capital cost of $2 million was assumed for CO controls (either projects to improve combustion or fuel feed or installation of a CO catalyst). Base cost estimates represent median costs for the various control scenarios based on published reports, industry and vendor information on specific project costs, EPA reports or control device fact sheets, or actual BACT or BART analyses previously submitted to permitting agencies.

To estimate capital costs for each boiler and process heater, we assumed that if there was no emissions information available for a particular unit, the unit would likely need MACT, which EPA stated in the preamble to the proposed Boiler MACT is a fabric filter (FF) plus carbon injection plus wet scrubber plus combustion improvements (or CO catalyst). For PM, if a unit did not already have a FF or ESP and there was information that indicated the unit cannot meet the proposed limit or there was no emissions information, we assumed a new FF. If the unit already had a FF or ESP and there was information that indicated the unit cannot meet the proposed limit we assumed an upgrade to the existing control equipment. To estimate control costs for HCl, if there was information that indicated the unit cannot meet the proposed limit or if there was no emissions information, we assumed either a scrubber upgrade or new scrubber depending on whether the unit currently had a scrubber. For Hg and dioxin, if there was information that indicated the unit cannot meet the proposed limit or if there was no emissions information, we added carbon injection. For CO, if there was information that indicated the unit cannot meet the proposed limit and is not a fluidized bed boiler, stoker boiler, suspension boiler, or dutch oven, then we assumed that capital would be necessary to either perform combustion and/or fuel feed improvements or other boiler/process heater improvement projects to reduce CO or install a CO catalyst.

Comment Excerpt Number: 4

Comment: The proposed MACT Standards did not take into account the technological and economic feasibility for some of the existing BTE facilities to meet the proposed emission limits. The supporting documentation to the MACT Standards stated that boilers with CO emission levels between 400 parts per million (ppm) and 1,000 ppm (at 3 percent 02) could install a Linkageless Burner Management Systems (LBMS) for under $20,000 dollars. However, there is no documentation that these systems can or have been successfully retrofitted to existing BTE facilities using stoker or fuel cell oven combustion to achieve the proposed levels. For units burning biomass, the draft regulatory analysis estimated that 72 percent of the units are exceeding the MACT floor emission limits, and that these units would need to install an LBMS. Based on ARB staff conversations with several stoker burner manufacturers, we could find no stoker units that have been retrofitted with these systems. Further, these manufacturers stated that a successful retrofit to meet the proposed standards was doubtful based on the inherent leakage of air in these types of facilities. In consulting with several LBMS manufacturers, none of these manufacturers were aware of any retrofits of stoker type boilers with a LBMS system. ARB recommends U.S. EPA conduct a more thorough analysis of the feasibility and costs for existing biomass facilities utilizing stoker or fuel cell/Dutch oven combustors to be retrofitted with a LBMS system.

Comment Excerpt Number: 4

Comment: Total cost of compliance extremely high for each mill due to the large number of boilers

* ESP to meet PM limits – $2 to $3 million capital cost per boiler

* Regenerative selective catalytic reduction (RSCR) to meet CO limit – $5 million minimum capital cost per boiler (assuming this technology is feasible on a bagasse boiler)

* Cost to replace a boiler with necessary controls: $30 to $50 million

* Average cost per boiler ~ $10 to $15 million

* Total cost to sugarcane processing industry ~ $250 to 350 million

Even most large industrial sources such as paper mills have only one or two boilers subject to rule; three individual sugar mills will have five or six boilers subject to the rule; one mill will have four boilers; and one mill will have three boilers

Comment: Comments on EPA's Cost Numbers and Approaches

EPA's cost impact figures are much lower than those projected by industry. This is likely due to an underestimate of the number of boilers that will require new air pollution control equipment due to the Industrial Boiler MACT limits. As described above, about 90 percent of the sugar industry's boilers will not be able to meet the proposed MACT standards based on current operation. EPA has likely not anticipated that many boilers may have to shut down rather than face the expensive task of retrofitting. If a plant or mill continues to operate, it may need to totally replace one or more boilers, as the existing boilers will not be able to meet the new limits even using the most advanced air pollution control equipment.

Comment: The capital cost to replace the NGSB "powerhouse" boilers, consisting of three residual oil-fired units, is estimated at between $30 million and $50 million. Even if modifications to, or replacement of, the boiler burners would allow the successful combustion of light distillate oil in lieu of residual fuel oil in the NGSB boilers, the additional cost of burning light distillate oil would increase NGSB operating costs by nearly $8 million annually based on fuel cost alone. In addition, boiler efficiency would suffer by as much as 4% when burning light distillate oil, directly thwarting EPA's goal of increasing boiler efficiency as a means of reducing HAPs. EPA erred when it did not take into account such cost and efficiency penalties in its regulatory impact analysis. Furthermore, even if light distillate oil could be successfully combusted, the NGSB boilers would still not be able to meet the proposed Boiler MACT emission limitations for liquid fuel-fired units.

Comment: EPA estimated that an ESP would be installed to meet the PM emissions limit unless a unit already had a fabric filter installed. We believe that since sorbent injection will be required for acid gas, mercury, and dioxin control, that fabric filters will likely be chosen for units without existing ESPs in order to maximize the performance of the sorbents and minimize the amount of sorbent used. For example, use of an ESP will require 4 times the carbon to be injected for mercury/dioxin control than if a fabric filter is used. The capital cost for a fabric filter is higher than the capital cost for an ESP on the same boiler.

Comment: EPA has estimated costs to install packed bed scrubbers for HCl control. Industrial boilers do not use packed bed scrubbers for acid gas control, as the limitations of these devices make them impractical for use on applications with high flow rates, high PM loading, and high inlet pollutant concentration. EPA's own fact sheet on these devices, located at http://www.epa.gov/ttn/catc/dir1/fpack.pdf, lists these limitations of these devices and indicates that they are only used in applications up to 75,000 scfm, which limits their use to small units only. Facilities will instead install wet scrubbers, dry scrubbers, or semi-dry scrubbers to control acid gas emissions from industrial boilers. EPA has estimated HCl control costs for equipment that industry is not likely to install.

CIBO/URS have estimated capital costs for coal, liquid, and gas 2 boilers and process heaters for HCl control of $9.3 billion, while EPA's capital cost estimate for wet scrubbers is $3.3 billion.

Comment: EPA presents several cost options in the two ERG memos. Option 2E assumes that facilities will not incur costs to comply with the dioxin/furan standards because they will test for dioxin/furan and be below detection levels. This is illogical, especially because EPA has not outlined in the rule any procedures for handling non-detects when performing compliance testing and there are boilers in the EPA emissions database with dioxin/furan emissions that are non-detect but actually measured emissions higher than the proposed limit. CIBO/URS has estimated carbon injection as the control measure for dioxin/furan emissions and mercury emissions. As stated above, our cost estimate for carbon injection for coal, liquid, and gas 2 boilers and process heaters is $1.7 billion versus EPA's of only $9.5 million.

In the event Work Practice Standards for Natural Gas fired boilers and process heaters are replaced with the numerical standards proposed in the preamble for Gas 1 boilers, the following costs were estimated using the same assumptions as above. We have assumed that gas 1 boilers and process heaters will apply the following technology: FF (for PM), carbon injection (for Hg and D/F), wet scrubber (for HCl), and CO catalyst. (See submittal for a table of costs for Gas 1 boilers).

The above estimates could be considered conservative since they assume that emission controls can be installed on existing units and that controls will actually allow compliance with the proposed emission limits. These are very conservative assumptions since it is known that retrofit of emissions control devices such as these is extremely difficult for some units due to design and space limitations, and major issues with the floor setting methodology make achievability of the emission limits highly uncertain. Therefore, it is likely that some combustion units will need to be replaced rather than retrofitting controls to those existing units. Replacement of combustion units could escalate these costs significantly.

Comment Excerpt Number: 14

Comment: Operation of oxidation catalyst for CO control would be subject to several design constraints. As an initial matter, oxidation catalyst performs optimally at temperatures of 600°F and above. Small boilers operating at turndown ratios may not be able to meet these temperatures. In particular, package boilers operating at low pressure and low load may experience low flue gas temperatures. [Footnote: The following represent typical outlet flue gas temperatures for package boilers:]
3 25% MCR 100% MCR
125 psig 3 pass FT
380F
460F
125 psig 4 pass FT
365F
400F
300 psig saturated IWT
454F
628F
750 psig 730F superheated IWT
559F
807FWhile an increase in volume and pressure drop may compensate for lower temperature, capital costs and operating expenses may increase. For example, a typical boiler producing 80,000 pounds of saturated steam is assumed to use a fan (at sea level) that moves 18,000 cfm at 14 inches of water column, and its energy consumption is 39.4 kw. The addition of a CO oxidation catalyst will add an estimated 2 inches water column to the draft losses of the system. This figure is based on typical design criteria, plus the need to compensate for low flue gas temperature. To the extent that the air moving equipment is capable of overcoming the added draft losses, the static pressure increase would result in a new energy usage of 45 kw, or 14%

increase. Other costs associated with the use of oxidation catalyst include the need for a near perfect flow distribution, which require flow straightening material or large amounts of catalyst material. The formation of sulfates is also a concern, because they may bond to the substrate of the oxidizing catalyst and create a potential for a sulfuric plume of SO_3, which may condense to form sulfuric acid. Further, in some field erected units, the installation of oxidation catalyst can reduce boiler heat exchange surface for lack of an adequate "window" for placement. Based on all of the above, oxidation catalysts may present technical and economic constraints that were not adequately evaluated by EPA. Further, even at optimal temperatures, use of an oxidation catalyst may not be sufficient to meet a 1 ppm emission level for CO. As an alternative, ABMA recommends a CO limit in the 5 ppm range where oxidation catalyst is used at optimal flue gas temperatures (>600°F).

Comment: Neither chloride nor mercury are typically measured by suppliers of liquid fuels such as residual oil or distillate oil, and there are no known reasonable, proven or cost effective fuel treatment technologies capable of removing chloride and mercury from liquid fuels. Fuel costs will increase considerably as suppliers attempt to meet new fuel specifications by obtaining or blending fuels from alternate sources that have lower naturally occurring levels of chloride or mercury. It is highly likely that it will not be possible to obtain No. 6 fuel oil meeting ASTM specifications and containing chloride and mercury at the levels sufficient to ensure consistent compliance with the proposed Boiler MACT regulation, forcing the costly shutdown and replacement of many No. 6 fuel oil fired boilers, including those at NGSB. It does not appear that such costs were considered by EPA during its development of the proposed regulation.

Comment Excerpt Number: 34

Comment: EPA has significantly underestimated the annual costs for coal and liquid-fired boilers by not including operational and maintenance costs in the economic analysis.

The U.S. Air Force conducted an independent assessment of the cost of compliance related to the proposed rule. This assessment resulted in 605 existing U.S. Air Force boilers, firing natural gas, liquid fuels or coal, being regulated on major HAP sources with a capital cost of $133.8 million and an annual recurring cost of $44.6 million. Using 7% interest and a 15 -year life for the capital cost, the total annualized compliance cost would be $59.3 million. The extrapolated total annualized cost for DoD would be $208 million based on the number of major HAP sources owned by each military service or $243 million based on the number of military emission units listed for each military service in the 1997 ICCR database.

In Table 11 of the preamble, EPA estimated that the nationwide impact would be 27,202 existing units to be regulated at an annualized cost of $2.9 billion which includes fuel savings. On page 32037-32038 of the preamble, EPA states that "the total capital and annual costs include cost for control devices, work practices, testing and monitoring." It further states that "Table 11 of this preamble shows the capital and annual cost impacts for each category. Costs include testing and monitoring, but not for recordkeeping and reporting costs."

For existing coal units, the EPA estimated annual costs at $62.4 million for 578 units or a cost per coal-fired boiler of $108,000. In contrast, the U.S. Air Force's preliminary assessment of recurring annual costs at $11.7 million for 6 units or a cost per boiler of $1.95 million. This annual unit cost includes testing and monitoring along with required "maintenance and operations" costs. It appears that the annual costs appearing in Table 11 did not include operations and maintenance costs for emission controls, which are significant and are driven by the emission limits. The annual costs appear to be limited to only testing and monitoring. Operations and maintenance costs will be incurred for existing coal units in sustaining the required emissions control devises linked to this regulation. These costs should be reflected in Table 11.

For liquid fuel-fired boilers, the EPA estimated annual costs in Table 11 at $27.4 million per year for 826 units, or $33,000 per unit. In contrast, the U.S. Air Force's preliminary assessment of recurring annual costs at $ 57.6 million for 51 units or an annual recurring cost per boiler of $1.13 million. This annual unit cost includes testing and monitoring along with required "maintenance and operations" costs. It appears that the annual costs appearing in Table 11 for liquid fuel-fired boiler did not include annual operation and maintenance costs for emission controls which will be required to meet the carbon monoxide (CO) limit of 1 ppmdv.

The primary driver for the elevated annual recurring costs lies in meeting the emission limits for oil- and coal-fired boilers established in the proposed rule.

Reevaluate the economic impact of this NESHAP in Table 11 to account for the capital and annual recurring operations and maintenance costs for air pollution control equipment that will be required to meet the proposed emission limits.

Comment Excerpt Number: 61

Comment: For units larger than 100 MMBtu/hr, EPA explains that "the capital costs estimated for installing controls on these boilers and process heaters to comply with MACT limits for the five HAP groups is over $14 billion." 75 FR 32025. While CIBO agrees with EPA's decision to act under section 112(h), the $14 billion figure grossly underestimates the cost of add-on controls by excluding the monitoring and operating expenses associated with such equipment. Other industry groups filing comments on this proposal have estimated that the capital cost of add-on controls for natural gas-fired units in EPA's database alone would be upwards of $50 billion for the subcategory. In reality, this number is likely even higher given that EPA's database does not include all the natural gas units in the country that would be affected by this rule and this estimate assumed that controls can be installed and that they can actually achieve the emission limits contemplated by EPA. If replacement of the combustion units was required, costs would be even higher unless production was shut down, and that presents another whole set of negative economic impacts.

Response: See preamble for response.

Comment: CO Control Costs
EPA estimates 482 units will install CO catalysts to control CO emissions. It would be very difficult to retrofit CO catalysts to existing boilers and process heaters. It is also not assured that

such installation could actually achieve the emissions limits proposed. CIBO recommends that EPA re-evaluate the approach taken and the data used to account for actual achievability and costs. CIBO believes the actual retrofit cost for CO catalysts will be very high.

Due to the lack of widespread deployment of CO catalysts on industrial solid-fueled boilers, many boiler owners are likely to view this technology as inherently more risky than traditional in-furnace techniques to control CO. The most commonly employed and cost effective method reducing in-furnace CO formation would be to "de-tune" the furnace by removing low-NOx firing systems and installing 1960's vintage burner systems that produce very low CO. Many companies will view this as posing significantly less technological risk than CO catalysts, due to their widespread use in boilers. As has been long established in the industry, a generally inverse relationship exists between CO and NOx in a well-tuned boiler. However, many industrial boilers are already either obligated to meet a specific NOx emissions standard, or to optimize NOx to achieve compliance with NAAQS Ozone standards, or both. Therefore the net effect of this CO standard will be to drive companies to "de-tune" their furnaces to control CO, and retrofit capital intensive NOx reduction technologies (e.g. Selective Catalytic Reduction) to control the resultant increase in NOx. EPA's own literature (EPA/600/SR-01/087 January 2002) provides a capital cost estimate of $50-110 per kW. Because these cost impacts have not been factored into EPA's estimates of the costs for controlling CO, EPA's estimates are significantly low. EPA should revise its estimates of the cost to industry to reflect one of the least technologically risky, and therefore one of the most probable, responses of many companies to comply with this standard.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 117

Comment: Since the proposed emission limits are unachievable simultaneously and under all operating conditions without add-on controls, all gas and liquid units subject to emission limits will have to install CO controls, rather than just a limited set as EPA assumed. Most, in addition to those identified in the Agency estimates, will also have to install PM, Hg and HCl controls to handle normal variability, since those limits also apply at all times. PM controls will be needed for every installation of oxidation catalyst, since the catalyst system generates PM2.5 emissions (sulfuric acid aerosol) in addition to each activated carbon Hg or dioxin control system. In Attachment F, we discuss the full range of control need engendered by this proposal.

On page C-6 of the RIA, it is reported that catalytic CO controls were only assumed for gas and liquid fired boilers and process heaters with baseline CO emissions above 1000 ppm. This is an unreasonable assumption. Essentially all boilers and process heaters will have to install catalytic CO controls, in order to meet the proposed CO limits at all times, while meeting the other applicable limits, particularly any applicable NOx limit. For the limited number of units that may be able to meet the proposed CO limits at all times without oxidation catalyst, Selective Catalytic Reduction (SCR) controls for NOx would be needed because low-CO operating conditions greatly increase NOx production. It is likely sources would opt for the CO controls in this case, rather than installing NOx SCR, since oxidation catalyst may help meet the dioxin/furan limit and oxidation catalyst, unlike SCR, does not generate ammonia emissions. Therefore, installation of CO oxidation catalyst on all gas- and liquid-fired units subject to emission limits is the basis we suggest be used in estimating the costs for this proposal.

Recommendation: Revise all cost and benefit analyses to assume CO oxidation catalyst and PM controls on all gas- and liquid-fired units subject to a CO emission limit and Hg and HCl controls on 94% of all units. Assume a reasonable percentage will need to be replaced in order to accommodate the controls. Include the costs and burdens associated with revising the existing boiler or process heater to accommodate the controls and the lost production associated with the outages needed to install the controls or replace units.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 252

Comment: The past 20+ years have been focused on the most efficient reduction of NOx emissions while maintaining reasonable levels of CO (50 to 400ppm). This has resulted in the use of techniques such as fuel and air staging which attempt to utilize the maximum extent of the boiler furnace volume available for combustion. This is particularly true for oil fuels, where fuel bound nitrogen accounts for the major portion of the NOx formation. Staged air combustion, either through burner design or in conjunction with separate air ports (i.e. NOx ports or Over Fire

Air) is one of the most effective methods of reducing the conversion of fuel bound nitrogen to NOx.

* Reducing CO to extremely low levels will require a shift away from these energy efficient techniques to methods that increase operating costs (i.e. higher FGR rates, back-end cleanup, etc.).

Comment: The petroleum and petrochemical industry operates several thousand gas-fired process heaters and boilers at refineries and petrochemical plants. The majority of these are “natural draft” design, meaning that mechanical means such as forced draft and/or induced draft fans are not used to induce gas flow. The gas flow is induced primarily by stack gas buoyancy, created by the difference in temperature and elevation between the stack gas and ambient combustion air, and to a lesser extent by entrainment induced by fuel pressure. The combustion air flow is regulated via manually-operated mechanical air registers located on each individual burner. A stack “draft” damper also may be used to control pressure differential between the ambient air and the stack to reduce the impact of cross winds or load swings on fuel-air balance. There is a wide variety of process heater designs depending on duty, with differences in heat input capacity, number of individual burners (from less than 10 to more than 100), firebox geometry (single furnace, dual furnace, cylindrical and rectangular geometry, aspect ratio, radiant heat transfer surface arrangement and placement), furnace exit temperature, burner type (radiant wall, jet, etc.), burner placement (bottom, side, top, combinations thereof), convective heat transfer surface arrangement, stack exhaust temperature, and other factors (e.g., Figure 12).

The furnace duty is especially critical as this establishes the combustion environment controlling CO and NOX emissions. Typically, the burners must deliver a precise range of radiant heat transfer to the furnace heat transfer surfaces to achieve the required fluid temperature for the process. This places limits on the range of variations in burner operating conditions for emissions tuning purposes.

In EPA's Regulatory Impact Analysis, MACT emission controls for HAPs include:
* CO: combustion controls and oxidation catalyst;
* Filterable PM: fabric filter or ESP;
* Mercury: activated carbon injection (ACI) plus fabric filter;
* Dioxins/furans: activated carbon injection plus fabric filter; and
* HCl: packed bed wet scrubber.

It is likely that most process heaters will not meet one or more of the proposed limits for Gas 2 or the prospective limits for Gas 1. These would need to install combinations of the emission control technologies described above. Figure 13 illustrates a typical vertical pipestill heater, a common design in the 40-80 MMBtu/hr capacity range. Figure 14 illustrates the same unit with all of the above MACT controls installed.

Assuming typical stack temperatures of 500-800 0F, the oxidation catalyst would be the first device because oxidation catalysts are more efficient at higher temperatures, minimizing the amount of catalyst required. Typical pressure drop across a catalyst unit and duct work routing the gas from the stack to the catalyst is 4 to 8 inches of water (representing much of the available pressure from natural draft).

The next device in line would the ACI system and fabric filter, comprised of a sorbent storage silo, feeder, compressor, spent sorbent storage silo, injectors, the fabric filter and utilities. In addition to reducing mercury and dioxins/furans, the fabric filter is needed to capture the particulate matter added as sorbent. The fabric filter is the largest physical component of the system, approximately the same physical volume as the process heater itself and greater. It is assumed that the dust (consisting mainly of spent sorbent) collected in the fabric filter would be transported to a waste disposal facility.

The gas temperature would need to be decreased prior to the ACI/fabric filter system (typically to 300 0F or lower) to facilitate mercury adsorption on the sorbent and to minimize potential dioxin/furan formation (which has been shown to occur at temperatures of approximately 300-800 0F if precursors are present). While this could be achieved with a water quench, this would be a wasteful use of water resources. An air preheater or waste heat boiler is typically the optimum engineering choice for reducing exhaust temperature. An air preheater would require construction of a new windbox to direct the heated air to the burners; in many cases this would be impractical due to burner arrangement. The air preheater (or waste heat boiler), fabric filter and associated ductwork would add perhaps another 8 to 12 inches of water pressure resistance to the gas path.

The wet gas scrubber for HCl removal would be next component in the gas path, comprised of the packed tower absorber, two to three tanks (caustic, recirculation and blowdown),

recirculating and caustic pumps, and make-up water supply. The packed tower absorber would be the largest physical equipment component, approximately the same size as the process heater or slightly smaller. The pressure drop across a packed bed scrubber and associated ductwork is typically in the range of 12 to 20 inches of water.
The addition of the above controls will require the addition of a new stack, since the existing integral stack above the process heater would be replaced by ductwork. Because of the low gas temperature leaving the scrubber, it is likely that the stack gas would need to be reheated to gain sufficient plume rise even with a taller stack. The energy for the stack gas reheat coils would typically be supplied as steam, and may represent a few percent of the total fuel energy consumed in the unit.

Because of the amount of pressure for inducing combustion air flow that is generated by natural draft is much less than that achievable with electrically-driven or steam-driven fans, any added flow resistance to the gas path becomes significant. Adding post-combustion emission controls typically must be accompanied by addition of forced draft and induced draft fans. This allows the absolute pressure within the system to be “balanced” to avoid over-pressure or under pressure in the unit that could lead to structural failure. It also allows a slight negative pressure to be maintained within the process heater and the emission control equipment for safety purposes (to prevent leakage of combustion gases around the equipment and consequent worker safety risks).

The physical size of the above emission controls requires 2 to 3 times the footprint of the process heater or boiler itself. In most refineries, the units are arranged tightly together (e.g., Figure 15). Existing space around process areas is designed to permit maintenance access (cranes, large vessel transport, etc.) and to provide safe distances between units and worker escape routes in the event of a safety hazard. This would require elevating the added equipment above the unit, with consequent requirements for large new foundations and extensive structural steel. Elevating the equipment adds significantly to the overall cost of the retrofit, perhaps 2 to 5 times that of the basic equipment installation itself when all preliminary and detailed engineering and construction costs are factored in. The costs would be much greater than EPA‘s estimates given in the RIA, which typically used retrofit factors of 1.2 to 1.4. In many retrofit cases, the overall cost is likely to be so great, or otherwise infeasible due to space constraints or other engineering issues, that it is more cost-effective to completely replace the unit. When this scenario is multiplied by the typical 40 to 60 process heaters in a major refinery, the total impact would be enormous.

Comment: A summary of the potential capital costs associated with upgrades necessary to comply with the alternative numerical MACT floor limits, including a comparison to EPA's estimates, is provided below: [See Table 11. Comparison of EPA and API Total Installed Capital Cost (CI) Estimates ($)]

API's total estimated cost for pollution control upgrades for Gas 1 sources is approximately $39.7 billion versus EPA's estimate of $20.9 billion, a 90 percent difference. It should be noted that API estimates are likely on the low side due to the potential underestimate of the number of affected units in EPA's database and the likely exclusion of potentially major costs that are impossible to reliably estimate at this time. While EPA's capital and operating cost estimates were generally reasonable for units requiring control device upgrades to fabric filters, wet scrubbers, catalytic oxidation and activated carbon, it is believed that EPA grossly underestimated the number of units that would be required to install catalytic oxidation and mercury/dioxin furan controls leading to a significant underestimate of costs by EPA.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 275.

Comment: UNDERESTIMATED POPULATIONS OF GAS 1 AND GAS 2 UNITS

National annual cost impacts discussed in this report are based on statistics provided by EPA pursuant to the 2008 Boiler Survey, which indicated that 11,532 Gas 1 and 199 Gas 2 BPHs would be impacted by the proposed rule. However, EPA reported in the proposed NESHAP for the vacated BPH NESHAP promulgated in 2003 that a total of 46,982 Gas BPHs would be affected. The reason for the 4-fold decrease in the estimated number of existing affected units in the BPH Source Category is unclear and has not been recognized by EPA in the supporting documentation related to the development of the proposed rule. If EPA has indeed underestimated the number of Gas 1 and Gas 2 units that will be impacted by the recently proposed BPH NESHAP by a factor of 4, the cost impact estimates developed by both EPA and API that are discussed in this report are also 4 times lower than the actual cost impacts.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 275.

Comment: REPLACEMENT OF BHPS

It is likely that a significant number of existing BPHs that would be affected by the BPH NESHAP are structurally designed and/or situated such that installation of extensive control technologies and associated equipment on those BHPs is infeasible. In such cases, it is expected that compliance with the proposed rule would require installation of new replacement BHPs with different structural design or in a more feasible location to allow connection with air pollution controls. Likewise, the potential impacts of extended outages with existing BPH modifications to facilitate installation of control equipment could necessitate the replacement of BPHs in order to reduce production downtime and outages during construction/commissioning. Obviously, the cost impacts of the BPH NESHAP on any facility requiring replacement units could be devastating, and if any appreciable fraction of the entire population of units is replaced, the total Subcategory-wide impacts would be enormous.

Based on limited data provided by several API member companies, the average total installed cost of replacing a 250 mm Btu/hr boiler and process heater is roughly $29.3 million and $31.5 million, respectively. The number of Gas 1 and Gas 2 units that might need to be replaced to accommodate the new pollution control equipment is unknown; however, one API member indicated that up to 50 percent of such units might need to be replaced.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2699.1, Excerpt Number 11.

Comment: Catalytic oxidation controls were assumed to only be required if a unit's baseline emissions exceeded 1000 ppm of CO, resulting in a very small percentage of units requiring catalytic oxidation controls. EPA provided no scientific basis or reasoning to support the logic that tune-ups and replacement burners alone could meet the proposed emissions limits.

With respect to CO, it seems implausible that tune-ups and burner replacements alone will enable virtually all emissions units to comply with the proposed limits during all operations (even during startup and shutdown) with no increase in energy consumption, NOx emissions, or other regulated pollutant emissions. Although it may be possible that some units not achieving the MACT Floor could comply through implementation of these relatively minor adjustments, extensive study would be required to determine the wide-spread feasibility of achieving the MACT Floors with tune-ups and/or burner replacements.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 117.

Comment: For mercury and dioxin/furan controls, EPA assumed that activated carbon injection (ACI) would be required if (in EPA's estimation) additional controls were necessary after any primary particulate matter and hydrogen chloride control upgrades were installed. The explanation of logic provided by EPA is vague and does not seem to harmonize with EPA's ultimate conclusion that only about 10 percent of units would require ACI.
Similarly, EPA's estimate that only a small percentage of units (roughly 1 percent) would require ACI controls does not seem plausible and was not supported in EPA's documentation. In the absence of scientific data supporting EPA's assumptions and drawing a direct correlation to Gas 1 and Gas 2 units, is seems more appropriate to assume that up to 94 percent of emissions units would be required to install add-on controls for abatement of CO and mercury/dioxin/furan.

Comment: CATALYTIC OXIDATION COSTS
Catalytic oxidation controls would most appropriately be located downstream of heat exchangers. The state-of-the-art control technology for catalytic oxidation in this environment is a system known as "regenerative catalytic oxidation (RCO)" manufactured by Babcock Power, which utilizes a proprietary catalyst to achieve necessary oxidation temperatures with nominal reheat. Trinity used a publicly available permit application reviewing this technology to develop a cost basis for this control strategy, which is included in Appendix A (Table A-1). [Appendix A (Table A-1) of the submittal].

Capital costs and capital recovery were estimated for individual affected units in EPA's database using the widely accepted 0.6 exponential scaling factor, which incorporates the economies of scale of equipment of different sizes, applied to information in EPA's Gas 1 and Gas 2 databases. Other annual operating costs were established based on the linear ratio of equipment sizes, operating hours and a capacity factor of 90 percent during actual hours of operation.

Comment: ACTIVATED CARBON INJECTION COSTS
ACI capital costs were developed for a 250 MMBtu/hr base unit using information provided by ADA Environmental Solutions, a leading activated carbon manufacturer and control system provider. Operating costs were estimating EPA cost methodologies, ADA having confirmed the reasonableness of carbon usage estimates, which comprise the majority of operating costs. A detailed cost breakout is provided in Appendix A (Table A-2). [See submittal for Appendix A's Table A-2.}
Capital and operating costs were estimated in the same manner as discussed for catalytic oxidation.

[See submittal for TABLE 2-1. TOTAL INSTALLED CAPITAL AND ANNUALIZED COSTS FOR POLLUTION CONTROLS ($/250 MMBTU/HR UNIT)]

Response: The EPA thanks you for your information.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 118

Comment: A significant percent of units will be unable to add controls to the existing unit because of space or structural constraints and thus new units will need to be constructed at greatly increased cost. The RIA estimates included no costs or burdens for replacement units or for installing NOx or CO controls on most Gas 2 and liquid fired units. Additionally, no costs were included for lost production while the boiler or process heater was being replaced or for the costs associated with such replacement units having to meet new source standards rather than existing source standards. Where the outage and/or cost associated with trying to meet these limits are excessive or the proposed limits cannot be achieved by any means, the units and their associated processes will be shutdown and jobs lost. The impact of lost jobs and economic activity is not reflected anywhere in the record.

Recommendation: Revise impact analyses to reflect that a significant percentage of sources and their associated processes will be shutdown and to reflect the resulting job losses.

Response: ******Cost Issue
The EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs. The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). This analysis was done on the national level for many reasons. Impacts on price level, international trade, national production, and jobs could not have been estimated if the analysis focussed on regional or state levels. EPA also does not have the necessary data to estimate impacts on individual states. Even if EPA had the data a detailed estimate of individual state and industry responses would be beyond the scope of what could be accomplished for this analysis.

Comment Excerpt Number: 144

Comment: There is no evidence that the controls EPA has identified work for gas-fired equipment or for boilers and process heaters firing all types of liquid fuels for all of the 5 classes of pollutants proposed for regulation. Nor is it demonstrated that estimates based on controls used for liquid- or solid-fired equipment are scalable to gas-fired units. As we have stated, it appears all possible controls will have to be installed on all units subject to numerical emission limits in order to try to meet the proposed limits at all times. Even then, it is not clear that compliance can be achieved and many units and their associated processes will have to shutdown to avoid non-compliance. In many other cases, the costs and burdens associated with this large and complex set of controls will be unsupportable, also resulting in process shutdowns and job losses.

We discuss the required controls in detail in Attachment F. Our following comments summarize some of the Attachment F information and expand upon it.

Response: See response for DCN EPA-HQ-OAR-2002-0058-1779, Excerpt Number 78.

Comment: On pages 32038 and 9 of the preamble, EPA discusses their analysis of the impact of this proposal on jobs. While the analysis appears robust, it is not, because it assumes all sources will be able to meet the proposed emission limits and because it uses the EPA estimates for the costs and burdens of compliance, which we have shown throughout these comments to be grossly underestimated.

One factor of specific importance that has not been addressed in detail in the Trinity report is the need to replace a particular boiler or process heater, in order to add the required controls. It takes a detailed engineering evaluation to determine where replacement is required, but we believe there will be many situations where a particular boiler cannot accommodate the add-on controls required for compliance. This can occur because 1) there is inadequate space for adding the additional equipment, 2) the furnace structure and foundations cannot accommodate the added equipment, or 3) the business cannot accept the extensive process outage associated with retrofitting the unit.

Space is a concern, particularly for process heaters, because these heaters by their nature are located close to the process equipment they serve. Thus, there is often little room to safely add fans and blower, catalyst beds, activated carbon facilities and provide for adequate space to service that equipment. Additionally, many process heaters have floor burners and in those cases, it is often impossible to add forced combustion air systems because of inadequate space for the ductwork under the heater. At significantly added cost, some of the space problem can be offset by building the controls vertically. However, the existing boiler or process heater structure and foundations often cannot accept the additional weight and wind load and adding foundations and structure adjoining the existing unit can put it at risk from the vibrations and construction activity. Converting a natural draft unit to induced draft, adding forced combustion air systems and changing out burners, which will be necessary in addition to the add on controls because of the addition of the forced combustion air system, will require long process heater and thus process outages, which often cannot be tolerated.

We believe these concerns will lead to replacement of many process heaters and some boilers. While it is difficult to generalize, Trinity estimates that replacing a 250 MMBTU/hr boiler or process heater in order to accommodate the required add-on controls will triple the cost versus retrofitting an existing boiler or process heater. Since this will be a common occurrence, the impact on the cost and burdens associated with this proposal will be extensive.

Recommendation: The jobs and national impacts analyses should be redone, assuming a significant percentage of gas- and oil-fired boilers and process heaters subject to these emission limits will be unable to meet those limits and that a significant percentage will have to be replaced in order to meet the proposal, using realistic estimates of the number of impacted boilers and process heaters in each subcategory units, and including all of the costs identified in these comments, not just a subset of costs as included in EPA estimates.

Comment: LOST PRODUCTION

There are numerous possible scenarios in which installation and operation of the control technologies that would be required to comply with numerical limits would result in atypical downtime that cannot be fully quantified due to the uniqueness of each process. Control device operational issues that could lead to interruptions in plant production might include the following:
* Unit downtime due to initial construction/commissioning of pollution control systems (e.g., process cannot operate normally during process of adaption of new control equipment)

* Unit downtime due to control device operational issues (control device malfunctions or requires unscheduled maintenance)
* Unit downtime due to required/scheduled control device maintenance (which may be extended for events that do not go as planned or where start up does not occur smoothly after maintenance is completed)
* Production outages can have major economic ramifications and should not be ignored, even though these impacts cannot be fully quantified at this time.

Comment: We estimate a cost of $30 million to install the required control measures in the plant I work in! The benefits of the Boiler MACT standard will be of dubious value to health or environmental protection. US boilers are already operate with efficient pollution abatement equipment and discharge at very low rates per unit output. The cost : benefit of the standard will be great. I am very skeptical of EPA’s published estimates of compliance costs at $9.5 billion. The wood products and pulp and paper industries alone are estimating a compliance cost of at least $6 billion.

Comment Excerpt Number: 4

Comment: The cost and benefit estimates and economic and regulatory analyses should be updated to reflect the underestimates of costs and overestimates of benefits in the current proposal and the actual impact the proposal on jobs and the economy. Among the major corrections needed are the following.

Retrofit control costs are underestimated and control retrofits are not technically or economically feasible in many locations due to a lack of plot space that meets required safety standards. Many units will require total replacement, if that proves economically viable.

Controls included in the EPA analysis have not been demonstrated to be effective at the low emission limits proposed for clean burning fuels (.e.g. gases and light liquids).

EPA has underestimated the number of boilers and process heaters affected by the proposed control requirements. There are many more Gas-2 and liquid-fired units than EPA estimates.

Commenter Affiliation: Tim W. Sonnichsen
Document Control Number: EPA-HQ-OAR-2002-0058-2931.1
Comment Excerpt Number: 10

Comment: The economic effects on boilers located in Major HAP's Sources would be significantly greater due to the larger number of pollutants to be controlled. In this case, the rule provides better estimates the capital and annualized costs of equipment. Table 9 presents EPA's estimates. The existing 239 biomass units are projected to spend an average of $5.2 million dollars per unit on capital investments. This will add approximately $1.3 million dollars to the annual operating costs of the facility. In many instances, this will challenge the economic viability of the facility.

Response: See response for DCN EPA-HQ-OAR-2002-0058-0856.1, Excerpt Number 2.

Comment: I understand that several representatives of the wood-products industry, other owners and operators of biomass boilers, and several other industrial trade groups will provide comments on the MACT rules. Some will include the cost impacts to their facilities. Kindly consider their projections of the costs for achieving these MACT standards as real. (I helped prepare some of these estimates and can assure the EPA that they are, if anything, conservatively low for the retrofit of control technologies.)

Response: See response for DCN EPA-HQ-OAR-2002-0058-0856.1, Excerpt Number 2.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 65

Comment: Dow owns and operates one coal-fueled boiler at an existing major stationary source and thus is directly impacted by EPA's proposed rule. EPA has proposed emission limits for Hydrogen Chloride (HCl), Mercury, Carbon Monoxide, and Dioxin/Furan that may be unachievable and not measurable even if all known emission controls are installed at our existing facility. Dow estimates that our capital costs to install the anticipated necessary control equipment is in excess of $30,000,000 (based on EPA cost models with adjustments) and that our ability to meet the proposed emission limits for HCl and other pollutants remains in question due in part to the variable nature of the chlorine content of various coals that are combusted in our facility. Coal quality data from a three month period between February 4, 2010 and May 7, 2010 shows that the chlorine content varies from 0.14 to 0.4 wt%. Dow comments that the very high capital retrofit cost along with an element of uncertainty with respect to meeting the proposed emission limits is unreasonable, and will jeopardize the long-term viability of our coal-fueled source should this rule be finalized as proposed.

Comment: The Regulatory Impact Analysis Fails to Account for Cost of Retrofitting The Industrial Fleet of Boilers.

The Regulatory Impact Analysis (RIA) for this rulemaking provides an overly rosy picture of the ability of many American manufacturers to accommodate the costs of retrofitting the fleet of existing boilers to meet the proposed standards for existing sources. Boilers in many industry sectors are aging and it will not be feasible or cost-effective to retrofit these boilers to comply with the rule, necessitating their shutdown, and for the facilities that can afford it, their replacement. EPA has not evaluated this trend in its RIA. There is a body of readily available information about the decline of American industry within other federal governmental bodies and we submit that it would be arbitrary and capricious for EPA to ignore this body of information.

Document Control Number: EPA-HQ-OAR-2002-0058-2901.1
Comment Excerpt Number: 1

Comment: Although EPA's estimates indicate that the total capital cost will be $9.5 billion, AF&PA has estimated that the total capital cost of the rule will be over $20 billion. Based on AF&PA's review, EPA used incomplete and old data or information to derive their cost estimates. In addition, many of EPA's assumptions are not based on real world applications. Below are a few items that clearly show why EPA's cost analysis is grossly inaccurate.

EPA used the outdated Control Cost Manual and AF&PA based their cost estimates on more recent information, including actual vendor cost estimates, actual project costs, BACT and BART analyses, industry control cost studies, etc.

AF&PA used a CO catalyst cost 4 times higher than EPA's. AF&PA's is based on a recent quote from BASF and EPA's is based on the 1998 Control Cost Manual section on catalytic oxidizers for VOC control.

AF&PA's CO control capital costs are $1.2 billion for liquid and gas 2 and $1.5 billion for coal and biomass, where EPA's total estimate for CO control capital costs is only 13.9 million, mostly because they have assumed that tune-ups and replacement burners will be adequate for the vast majority of boilers to comply.

EPA has estimated that activated carbon injection will only be required on 155 existing boilers because installation of a fabric filter is expected to achieve the mercury emission limits, except in cases where a unit already has a fabric filter and does not meet the limits. AF&PA does not agree that fabric filters will be sufficient to reduce mercury emissions to the ultra low levels proposed in this rule. EPA's estimated industry-wide capital cost for activated carbon injection is only $9.5

million. AF&PA estimates for carbon injection required for mercury and dioxin/furan control is $1.7 billion.

AF&PA has estimated a PM control cost of $7 billion versus EPA's estimated PM control cost of $6.1 billion.

AF&PA has estimated capital costs for HC1 control of $9.3 billion, while EPA's capital cost estimate for wet scrubbers is $3.3 billion.

Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 2

Comment: In a calendar year, RMA members may use more than 10% liquid fuel during periods of curtailment, or as a back up fuel for natural gas. As a result, under the proposal, boilers at RMA member facilities would be classified as liquid fuel boilers. Liquid fuel boilers would be required to install costly add on controls to meet the liquid fuel emission limits under the proposed rule. RMA estimates that if classified as liquid fuel boilers, add-on controls (assuming the following spray dry absorbent with fabric filter, carbon injection, and oxidation catalyst (CATOX) control technologies would all be required) for RMA tire member's 56 major source boilers would cost a total of approximately $571 million dollars. Because this cost estimate does not include costs for emission monitoring and data logging systems, compliance testing, and operating and maintenance costs associated with the controls, we believe the total cost including monitoring and maintenance costs would be significantly greater than the $571 million for add-on controls.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2702.1, Excerpt Number 61.

Commenter Name: Michael Potter
Commenter Affiliation: Goodyear Tire and Rubber Company

Document Control Number: EPA-HQ-OAR-2002-0058-3181
Comment Excerpt Number: 4

Comment: Goodyear currently has sixteen natural gas boilers with backup capability to burn fuel oil located at tire plants that are major sources of HAP emissions, and that would be subject to the proposed standards. In addition Goodyear has several boilers with liquid fuel capability at chemical plants and at HAP area source plants. The sixteen tire plant boilers with backup oil capability range in size from 75 million Btu per hour heat input to 190 million Btu per hour heat input. Although Goodyear is not sure that technology exists to simultaneously meet proposed oil subcategory emission standards for all regulated pollutants on a reliable basis, Goodyear has attempted to estimate the capital costs that would be required to meet oil subcategory standards should backup fuels be needed for more than 10 percent of annual fuel input.

Assuming the following spray dry absorbent with fabric filter, carbon injection, and oxidation catalyst (CATOX) control technologies would all be required, Goodyear estimates the capital cost would average about $12 million per boiler, or about $192 million just to preserve the ability to use backup fuels for extended periods in Goodyear's boilers currently equipped with backup fuel capability in the five Goodyear tire plants that are major HAP sources. These estimates do not include costs for emission monitoring and data logging systems or for compliance testing, nor do they include operating and maintenance costs associated with the controls, which are unknown but Goodyear anticipates would be substantial. Costs for Goodyear's chemical plants have not been estimated.

Goodyear believes this cost would be unreasonable and warrants reconsideration of the proposed regulations as otherwise described herein.

Comment: The economic analysis is clear. The Proposed Rule sets numeric emission limits for five pollutants (PM, HCl, Hg, dioxin/furans, and CO). At this time, coke oven gas-fired units are not controlled for these compounds. Using EPA's projected cost of control (annualized capital cost plus annual operating cost) for each pollutant, including monitoring, recordkeeping and reporting, an ACCCI member company has calculated an annualized cost of control of $8.6 million for a single 650 MMBTU/hr combusting coke oven gas. At a cost of $5/MMBTU for natural gas, it is economically unreasonable for the boiler operator to use coke oven gas to displace the first 1,720,000 MMBTU per year of natural gas in this boiler and the coke oven gas would be flared. The use of natural gas to replace coke oven gas in this situation would be to the detriment of the environment and our energy policies.

The constraint on available capital is an additional impediment to the installation of emission control equipment because increased natural gas consumption does not require a capital investment. Before a company will invest $8.6 million in annualized control costs for a single boiler, it will need to justify a return on the capital investment far greater than $8.6 million per year in displaced natural gas. Moreover, as discussed below, there is no expectation that expenditures of this magnitude will be sufficient to meet the proposed Gas 2 subcategory emission limits.
[Footnote 1: the capital cost for the unit is $27,747,000 and the annual non-capital cost is $5,678,000.]

Comment: MACT costs. It is believed the costs of the proposal are greatly underestimated and do not take into account the man power requirements for implementation of the requirements. Increased costs are not only due to pollution control requirements, but also continued record keeping activities, development of plans and submittal of such plans, communication, and implementation. The costs of increased greenhouse gases and effect on the environment has not been fully captured, e.g., no beneficial reuse of coal fly ash, increased power generation for pollution control equipment, increased water utilization and wastewater processing, and disposal of combustion by products and increased NO, emissions to meet the CO emission limit.
It will likely require at least two and possibly three emissions control devices on each boiler to pass the five emissions limits. At a minimum, it appears that a bag-house and a scrubber will be required and likely charcoal injection.
USEC fully supports API’s and NPRA’s contention that the costs and burdens of the proposed new rule will be many times those estimated.
- Essentially all boilers and process heaters would have to install
extensive controls, which would require outright replacement of the boiler or process heater in many cases due to I) lack of space for required controls at current location, or 2) potential structural issues with existing unit.

Comment Excerpt Number: 6

Comment: Even if it were feasible to physically place required emission control equipment at existing boilers and process heaters, the cost to install and operate the control equipment would be prohibitive. Based on an analysis of published equipment installations and our site-specific knowledge of construction costs in Hawaii, Tesoro's assessment of the likely cost to install and operate the control equipment configurations identified above on a typical 100 MM Btu/hr process heater at its Kapolei Refinery is:

Scenario #1:
Capital equipment and installation: $4 million
Annual operating cost: $1.5 million

Scenario #2:
Capital equipment and installation: $6.5 million
Annual operating cost: $1.4 million

Accordingly, to control the existing boiler and process heaters at the Kapolei Refinery we estimate that a capital cost of approximately $44 to $72 million would be incurred, along with annual operating expenses of approximately $17 million.

Current and reasonably-anticipated future economic conditions would probably not allow Tesoro to make this capital investment and sustain the recurring increase to the refinery's operating expenses.

Comment: The paucity of dioxin/furan data is also demonstrated within the cost estimating methodology, which does not estimate cost for dioxin/furan controls since it is assumed that dioxin/furan emissions will be below detection limits and that activated carbon used for mercury control will also control dioxin/furan. In the cost estimate for the proposed rule the following is assumed:

"it does not estimate ACI [activated carbon injection] for units exceeding the MACT floor emission limit for dioxin/furan. Instead, it is estimated that most units, when testing for dioxin/furan will be below detection levels without installing any additional control devices." [Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source EPA-HQ-OAR-2002- 0058-0812(2)]

If this assumption that dioxin/furan will be below detection limits without installing additional controls is true, then why set a limit in the proposed rule for material which cannot be measured effectively and does not require additional control? Belief that emissions will remain below the detection limit with so much uncertainty about testing methods, meaning of test data and mechanisms of formation and control is hardly a prudent basis for assuring that compliance will be achieved on a continuous basis with prescribed emissions limits that are difficult or impossible for some credible samplers and laboratories to measure.

Comment: Contacted fifteen vendors for information (control efficiency, cost, etc) on application on gas fired boilers and process heaters. None of the vendors reported commercial application on gas fired units. Some vendors have application(s) on coal fired combustion sources.

The vendors indicated significant uncertainty associated with control efficiency and cost for gas fired units because of the much lower initial pollutant levels (than those from coal fired units) and the extremely low emission limits proposed, plus the lack of application experience.

To assess the emissions reductions required for the pollutants under consideration to achieve the proposed Gas 2 limits, the means of the EPA MACT floor raw data are assumed as baseline emission levels. Emission reductions for the pollutants are calculated by subtracting the baseline emissions from emissions at the proposed limits. The removal efficiencies required to meet the proposed limits and the assumed controls are summarized in the table below. (see submittal for table.)

A removal efficiency of 99.9% is required to meet the proposed limit for HCl. For units with HCl emissions above the mean of the MACT floor data, a removal efficiency of greater than 99.9% would be required. Wet scrubber is assumed to be the control. The removal requirement is higher than vendor reported typical HCl control efficiencies in waste incineration or coal combustion applications. Control technology is generally less efficient at low initial pollutant levels. Emission reductions achieved by technologies designed for much higher initial pollutant levels present in waste incineration or coal combustion applications are likely to be substantially lower when applied to the low initial pollutant levels present in flue gas from gas fired units. Therefore, 99.9% removal of HCl would not be technically achievable.

A removal efficiency of 99.4% is required to meet the proposed limit for CO. For units with CO emissions above the mean of the MACT floor raw data, a removal efficiency of greater than 99.4% would be required. Catalytic oxidation is assumed to be the control. Lowering CO through combustion controls (i.e. fuel and air controls) increases NOx, fuel consumption, and other emissions (details in Comment II). While CO is used as surrogate for organic HAPs, it is uncertain if a catalyst can achieve the same reduction efficiency for HAPs as for CO.

Comment Excerpt Number: 18

Comment: A cost impact analysis was conducted by API to evaluate cost of the proposed MACT rule for all affected sources. The study compares the API's cost estimates with the EPA's cost estimates, and finds that EPA estimates grossly underestimate the costs for compliance. EPA significantly underestimated the number of units that would be required to install controls, since they assumed units operating at or less than 400 ppm of CO, only needed to perform a tune-up rather than installing controls to achieve the 1 ppm emission level. [See Page C-5 MEMORANDUM TO: Jim Eddinger, USEPA, OAQPS/SPPD, FROM: Susan McClutchey, etal, ERG, April 15, 2010 SUBJECT: Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source] Based on the API analysis, the total estimated capital cost for compliance for Gas 2 sources is approximately $2.4 billion (versus EPA's estimate of $1.5 billion, a 60 percent difference). This number does not even include operating costs. Costs required to operate the control devices include handling of solid waste, water use, caustic use, wastewater treatment, electricity, and maintenance.

The costs for compliance are unreasonably high while total emissions reductions are very small. As discussed in Comment II, gaseous fuels are clean burning fuels. Emissions of CO, Hg, filterable PM, and HCl from gas fired boilers and process heaters constitute less than 1% of respective total emissions from all sources nationwide. Requiring extremely low limits for gas fired boilers and process heaters will be ineffective in improving air quality.

Recommendation: EPA should evaluate the technological feasibility of applying the controls available to achieve the proposed numeric

limits to gas fired units and re-assess the cost impact of the proposed rule. EPA should not set emissions limit without regard to feasibility. EPA should avoid promulgating rules that despite requiring prohibitive capital and operating costs, will result in negligible emissions reductions, if any.

Comment: Courtland, AL - No. 2 Combination Boiler

The Courtland, AL - No. 2 Combination Boiler was identified as a floor unit for Hg and HCL in the proposed rule, however the test data for these pollutants was measured under normal operating conditions and fuel mix, and does not assure compliance under all operating conditions including the worst case fuel mix as required by the proposed rule. When the boiler was evaluated for compliance under the worst case fuel mix taking into account the variability of Hg and Cl in coal, we projected a need to install Hg and HCl controls to meet the proposed limits.

Further, we projected a need to also upgrade the existing ESP controls for PM with a bag house for removal of the additional particulate load associated with the carbon and sorbent injected for Hg/HCl control. Cost for carbon and sorbent injection and additional PM control in the form of a fabric filter is not included in EPA's cost estimates conjunction with more than 10% coal and cannot otherwise achieve the coal CO limits. In order for the CO catalyst to work along with the other required pollution control devices, we would need to reheat the flue gases to at least 450°F before the catalyst. These CO compliance costs are not currently reflected in the EPA cost estimate. This means the addition of Hg and HCl control systems at a cost of about $16 million and the CO catalyst at a cost of approximately $14 million for a total of $30 million in capital. The operating cost of these systems is $7.5 million per year not including capital recovery cost. These costs are not currently reflected in the EPA cost and economic evaluation.

Comment: Ticonderoga, NY – PB1

The Ticonderoga, NY PB1 power boiler was identified as a floor unit for Hg in the proposed rule. However the test data for Hg was measured under normal operating conditions and fuel mix, and does not assure compliance under all operating conditions including the worst case fuel mix as required by the proposed rule. When the boiler was evaluated for compliance under the worst case fuel mix taking into account the variability of Hg in biomass, we determined a need to install Hg controls to meet the proposed limits along with upgraded PM controls for removal of the additional particulate load associated with the carbon. The cost for this equipment is not included in EPA's estimates for this unit. This means the addition of an Hg control system at a cost of approximately \$1.2 million in capital. The operating cost of this system is \$0.3 million per year not including capital recovery cost. This Hg control cost for a floor unit is not currently reflected in the EPA economic evaluation.

Response: See preamble for response.

Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 23

Comment: Complying with the proposed Boiler MACT rule will cost International Paper an estimated \$629 million in capital cost and a total annualized cost (including capital charge) of approximately \$199 million dollars per year. This does not include the fuel replacement and disposal costs of the non-hazardous secondary materials designated as solid waste to avoid CISWI requirements. [see submittal for Attachment 1]

The basis for these cost estimates is included in Attachment 1 [The content of this attachment is confidential business information and has been submitted separately for inclusion in EPA's confidential business information files.] These costs are for IP's fleet of 42 boilers affected by Boiler MACT presuming CISWI is avoided altogether. The current limits are more stringent than needed to assure appropriate protection of health and the environment from industrial boiler HAP emissions. Using its discretionary authority under the CAA would allow EPA to craft appropriate rules that should yield more pragmatic regulatory results. International Paper also will experience annualized costs for the NHSM rule in the estimated amount of \$287 million per year and combined with Boiler MACT amounts to an estimated \$486 million per year.

Response: See response for DCN EPA-HQ-OAR-2002-0058-0856.1, Excerpt Number 2.

Commenter Name: David M. Kiser

Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 25

Comment: Not all required pollution control equipment is included in EPA's cost estimate.

There appears to be an error in the cost estimating method for determining if a CO catalyst is required for pulverized coal units. In the document describing the methodology for cost estimating it says;

"For PC-boilers, a tune-up was estimated in the cost analysis for any unit with a baseline of less than 1200 ppm @ 3% O2. The cost of a replacement LNB was estimated if CO emissions were between 1200 – 3000 ppm @ 3% O2 and catalytic oxidation was estimated if CO baseline was greater than 3000 ppm @ 3% O2.” [Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source EPA-HQ-OAR-2002- 0058-0812(2)]

However the CO limit for pulverized coal units is 90 ppm at 3% O2. For our pulverized coal boilers we have 8 units that burn a combination of coal and biomass and cannot meet the proposed limit without a CO control device. It is assumed for purposes of estimating compliance cost that a CO catalyst with reheat to 450 degrees F will meet the proposed limits; however this assumption, that a CO catalyst will meet compliance, is unproven as discussed elsewhere in this document. The estimate for the CO catalyst for the 8 affected units is $120 million with an annual operating cost of $63 million as shown in Attachment 1. [The content of this attachment is confidential business information and has been submitted separately for inclusion in EPA’s confidential business information files.] The current EPA estimate does not include these compliance costs for pulverized coal units firing biomass in conjunction with coal. Furthermore the cost algorithm should be revised to reflect the actual compliance cost for all units given the proposed limit of 90 ppm.

Commenter Affiliation: Ameren Services
Document Control Number: EPA-HQ-OAR-2002-0058-2803.1
Comment Excerpt Number: 29

Comment: US EPA’s estimate of costs underestimates the costs of controls by underestimating the cost of electricity to run those controls. Electricity costs are an annual cost of control and are a major component of the annualized cost of controls estimated. US EPA uses data from the US DOE Energy Information Agency to assess the annual cost of electricity associated with the cost of control. However, the US EPA erred by using data on national average reported revenue from industrial customers per net megawatt generated. The US EPA mistakenly associates utility revenue with industrial cost data which is inappropriate. The utility revenue data utilized does not include other costs borne by customers including taxes, distribution charges and environmental or other surcharges. In addition, similar higher revenue data per megawatt generated was also available for commercial accounts, however, this data was ignored despite the fact that the Boiler MACT affects commercial and institutional boilers.

Commenter Name: Michael Hutcheson
Commenter Affiliation: Ameren Services
Document Control Number: EPA-HQ-OAR-2002-0058-2803.1

Comment Excerpt Number: 30

Comment: The US EPA improperly overestimates energy and fuel savings associated with required energy audits, annual tune-ups and required combustion controls. US EPA should not include any energy savings associated with energy audits as these audits will not guarantee any energy savings. They are only assessments. Similary, US EPA's own data shows that affected units are already conducting boiler tune-ups (page 32025 of preamble which states, "The data we have suggests that units typically conduct tune-ups"). Consequently, US EPA should expect little benefit from boiler tune-ups as these are already normal practice throughout industry. As a result, Ameren believes that the fuel savings estimate of 1 % of annual fuel consumption is an overestimate and should be revised downward to reflect realistic estimates of fuel savings.

Response: EPA has retained its estimate of 1 percent fuel savings in the final rule. See memorandum "Revised Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source" for selecting this estimate.

Comment: 7. Costs at Remote/Island Facilities
a. General
Because of the distance of St. Croix from the continental United States, costs are inevitably higher for a given capital project at HOVENSA. (See submittal for outline of higher costs):

* Direct Costs
– Wage Rates
* Relocation incentives
* Per diem
* Housing costs
* Rotational leave
* Guarantees on minimum overtime
* Retention bonus – Productivity
* Quantity of Skilled Local Craft
* Limited local availability of higher level craftsman; i.e. fitters, welders, instrument technicians, electricians
* Off-location craftsmen not always from the top quartile – best working close to home
– Limited 3rd Party Services and Resources
– Lack of Competition
– Design Requirements
* Installed Spare Equipment
* Seismic/Hurricane/Tropical/Marine Design Specifications
* Capital Spare Parts Requirements
– Transportation Costs
* Ocean Freight
* Air Freight
* Vendor Representatives
* Construction Equipment
* Construction Tools
* Off-location Personnel
* Higher Turnover Rate
--Equipment and Tools Rental Durations
--Mobilization and Demobilization Travel pay to/from location
•
At HOVENSA, the result of these factors is that for a given capital project, costs for those projects are 1.3 to 2.3 times higher on average. We believe this is typical for non-continental facilities.

Response: See preamble for response.

Comment Excerpt Number: 126

Comment: EPA Has Underestimated the Cost of Boiler MACT

In this rulemaking, EPA has followed the costing assumptions and techniques in the OAQPS Control Cost Manual (EPA 452/B-02-001). ACC continues to believe this approach underestimates the total installed cost of air pollution control equipment. The Control Cost Manual has not been updated in many years, does not reflect the current costs, and is missing information on several control technologies. Because of these limitations, ACC believes EPA has grossly understated the capital and annualized costs of this proposed rule.

Due to the anticipated major financial impact of this rule on our industry, ACC has also estimated the capital costs for installation of additional control technologies on existing boilers and process heaters. ACC did not consider potential cost reductions that might result from emissions averaging or inclusion of health based emission limits in the final rule, and we assumed that the Gas 1 limits discussed in the preamble would not be promulgated. The approach used by ACC to estimate capital costs differed from EPA's in several respects, as described below.

We developed [see submittal for Appendix A, boilers Inventory costs.] a detailed spreadsheet estimating the costs for the proposed rule, based on EPA's major source boiler inventory database table.[See Appendix A (Boiler Inventory 07-09-2010 Costs.pdf).] Since the proposed rule does not include emission limits for natural gas boilers or boilers less than 10 MMBtu/hr heat input, these units were not included in the cost analysis. Based on the information in the EPA emissions database on boiler size, fuel, existing controls, and emissions, we estimated costs of controls that would likely be necessary to comply with the proposed standards for coal, biomass, liquid, and Gas 2 boilers and process heaters.

Information from various sources was used to determine a base capital cost for a 250 MMBtu/hr boiler for each PM and HCl control technology option and then scaled using a 0.6 power function based on the size of each boiler/process heater in the inventory. For example, the base capital cost of a scrubber on a 100 MMBtu/hr boiler is calculated as the base cost of $8 million times (100/250)0.6. A fixed capital cost of $1 million was assumed for installation of a carbon adsorption system for Hg and/or dioxin control, as these systems do not vary much in cost by boiler size. A fixed capital cost of $2 million was assumed for CO controls (either projects to improve combustion or fuel feed or installation of a CO catalyst). Base cost assumptions are presented in Appendix A [see submittal for Appendix A.] It should be noted that the goal was not to create a worst-case cost estimate for each boiler. Rather, the cost estimates represent median costs for the various control scenarios based on published reports, industry and vendor information on specific project costs, EPA reports or control device fact sheets, or actual BACT or BART analyses previously submitted to permitting agencies.

To estimate capital costs for each boiler, we assumed that if there was no emissions information available for a particular boiler or process heater, the unit would likely need MACT installed, which EPA stated in the preamble to the proposed rule is a fabric filter (FF), carbon injection, wet scrubber, and combustion improvements (or CO catalyst). For PM, if a unit did not already have a FF or ESP and there was information that indicated the unit cannot meet the proposed limit or there was no emissions information, we assumed a new FF. If the unit already had a FF or ESP and there was information that indicated the unit cannot meet the proposed limit we assumed an upgrade to the existing control equipment. To estimate control costs for HCl, if there was information that indicated the unit cannot meet the proposed limit or if there was no emissions information, we assumed either a scrubber upgrade or new scrubber depending on whether the unit currently had a scrubber. For Hg and dioxin, if there was information that indicated the unit cannot meet the proposed limit or if there was no emissions information, we added carbon injection. For CO, if there was information that indicated the unit cannot meet the proposed limit and it is not a fluidized bed boiler, stoker boiler, suspension boiler, or dutch oven, then we assumed that capital would be necessary to either perform combustion and/or fuel feed improvements or other boiler/process heater improvement projects to reduce CO or install a CO catalyst.

Although EPA's estimates indicate that the total capital cost will be $9.5 billion, ACC has estimated that the total capital cost of the rule will exceed $20 billion for industry, with $3.8 billion in costs for the chemical industry (boilers listed as NAICS 325 in the EPA database). It is evident based on our analysis that major capital investments in add-on control technology will be required for continued operation of chemical industry boilers if the rule is finalized as proposed.

While the above estimate appears very high compared to the EPA estimate, we believe this estimate to be very conservative, since this methodology assumed that controls could actually be installed and could actually achieve the emission levels proposed by EPA. Realistically, many units will simply not be able to be retrofit with controls and/or will not be able to meet the emissions limits regardless of controls, so that total combustion unit replacement would be required, which would greatly expand the cost of the rule for individual facilities. Based on feedback from ACC members, replacement of boilers and process heaters will occur at many facilities because the existing units cannot be retrofitted with the required controls due to 1) lack of space for the required controls at the unit's current location, or 2) potential structural issues with the existing unit. That inability to retrofit or meet the emission limits will either result in (1) shutdown of marginal production facilities with a loss of jobs and collateral negative economic impact at all social levels or (2) addition of significant capital cost, since the cost will include not only control equipment necessary to meet new source requirements, but the cost of the replacement unit as well. We believe that EPA has failed to consider these likely impacts since it has simply not considered achievability of the emission limits it is proposing. Without this consideration, the true cost and collateral impacts of the proposed rule are not fairly represented or discussed, calling into question the legitimacy of this rulemaking.

Response: See preamble for response.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 136

Comment: EPA used a catalyst cost of $959.25 per cubic foot from Chapter 2 of the OAQPS Control Cost Manual, according to Table 1 of the ERG cost methodology memo. [EPA-HQ-OAR-2002-0058-0803]We assume this means Section 3, Chapter 2, VOC Destruction Controls, dated 2002. Page 2-45 indicates that this cost is based on a 1998 estimate of $650/cubic foot, and we assume that ERG scaled this estimate up to 2008 dollars. Based on a May 2009 cost estimate obtained from BASF by our consultant, URS Corporation, for use in a BACT cost estimate for a CO catalyst on a forest products industry boiler, BASF estimated a cost of $4000 per cubic foot for catalyst modules and supports. As EPA has other information from BASF regarding their technology in the docket for this rulemaking, [EPA-HQ-OAR-2002-0058-0781] EPA should also have confirmed its cost estimating techniques for CO catalyst installations rather than using outdated cost methodology applicable to catalytic oxidizers for VOC control, which are of different design than a CO catalyst system. EPA should update its CO catalyst costs.

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 137

Comment: We do not agree with the methodology used to determine the cost of CO emissions reductions for boilers with CO emissions less than 400 ppm @3% O2. The ERG cost and emissions impacts memo states that the cost of a tune-up was estimated if the unit's baseline emissions exceeded the floor for CO but were less than or equal to 400 ppm at 3% O2. Based on conversations with boiler and burner vendors, there are certain boiler and burner designs that cannot achieve the proposed emission limits with a simple tune-up, especially in cases where a low NOx limit must simultaneously be achieved or where biomass is being burned with coal. For combination coal/biomass stoker boilers to achieve the 50 ppm CO limit, it will take more than a tune-up; it will likely take more expensive fuel feed and/or combustion improvements. For many liquid and gas boilers to achieve a 1 ppm CO limit, it will take more than a tune-up; these boilers with low NOx limits will likely face installation of a CO catalyst, which has not been proven to achieve the proposed emission levels on boilers and process heaters. The ability to retrofit CO catalyst systems on existing boilers and process heaters is a major issue that should be addressed by EPA.

Comment: We do not agree with the methodology used to determine the cost of CO emissions reductions for liquid and gas-fired boilers. The ERG cost and emissions impacts memo states that if baseline CO emissions were between 400 and 1000 ppm for boilers and process heaters designed to burn liquid and gaseous fuels, the cost of a low-NOx burner was estimated to achieve the proposed MACT floor emission limits. The CO limits for these boilers in the proposed rule are 1 ppm. Based on conversations with burner vendors, a low-NOx burner is typically guaranteed to produce CO emissions of 50 to 100 ppm for gas and liquid boilers. Recently installed burners have not been shown to achieve the proposed CO emission levels. EPA's unfounded assumption that burner retrofit can result in achieving these levels is simply unfounded, and the Agency should provide justification for why they believe this is an appropriate approach or re-evaluate its assumption.

Comment: EPA's cost estimates for CO controls assume that tune-ups and LBMS will achieve very high CO reductions. This assumption is false and may stem from a misunderstanding of how industrial systems are operated. Much of industry has been operating under extreme financial constraints and lowering costs has been a high priority for a long time. Many combustion units are routinely operated at optimum efficiency so that there is no further opportunity for combustion efficiency adjustment. In fact, EPA's proposed approach to tune-ups with a focus on minimizing CO emissions will, in most cases, result in use of increased excess air and thereby decreased efficiency and increased emissions overall, counter to EPA's contention of a 1% efficiency improvement with tune-ups. EPA's total estimated capital cost of $13.9 million for combustion controls and oxidation catalysts presented in Table 2 of the cost and emissions impacts memo is extremely low and a gross underestimate of the actual costs that industry boilers will incur to comply with the CO limits in the rule. The liquid and Gas 2 limits of 1 ppm in particular will impose extremely high costs for control on some units. EPA should re-evaluate its assumptions with respect to the effect of tune-ups on emission levels and fuel use.

Comment: EPA has estimated that activated carbon injection will only be required on 155 existing boilers because installation of a fabric filter is expected to achieve the mercury emission limits, except in cases where a unit already has a fabric filter and does not meet the limits. We do not agree that fabric filters will be sufficient to reduce mercury emissions to the ultra-low levels proposed in this rule. There are a number of flaws in EPA's logic that fabric filters are expected to achieve mercury emission limits. First, there are many boilers in the database that are equipped with fabric filters and have measured mercury emissions higher than the proposed limits. Second, when burning fuels containing mercury with fuels containing sulfur (e.g., biomass with TDF, oil, or coal), mercuric sulfate is formed, which is a particulate that can be captured in a fabric filter, but when fuels such as biomass and natural gas with low mercury contents are burned without sulfur-containing fuels, elemental mercury is the primary emission and is not captured in a fabric filter. EPA's estimated industry-wide capital cost for activated carbon injection presented in Table 2 of the cost and emissions impacts memo is extremely low, at only $9.5 million. We do not understand how this can represent 155 boilers; it seems to us to represent the cost 10 boilers would incur to install a carbon injection system. EPA should re-evaluate its mercury control costs.

Comment: In its Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source document, EPA estimated that an ESP would be installed to meet the PM emissions limit unless a unit already had a fabric filter installed. We believe that since sorbent injection will be required for acid gas, mercury, and dioxin control, that fabric filters will likely be chosen for units without existing ESPs in order to maximize the performance of the sorbents and minimize the amount of sorbent used. For example, use of an ESP will require 4 times the carbon to be injected for mercury/dioxin control than if a fabric filter is used. Using EPA's cost algorithms, installation of a fabric filter has a higher capital cost than installation of an ESP; therefore this assumption results in an underestimate of the capital cost required to meet the proposed PM limits.

Comment: EPA has estimated costs to install packed bed scrubbers for HCl control. Industrial boilers do not use packed bed scrubbers for acid gas control, as the limitations of these devices make them impractical for use on applications with high flow rates, high PM loading, and high inlet pollutant concentration. EPA's own fact sheet on these devices, [Available at http://www.epa.gov/ttn/catc/dir1/fpack.pdf] lists limitations of these devices, indicating that they are only used in applications up to 75,000 scfm, which limits their use to small units only. EPA has estimated HCl control costs for equipment that industry is not likely to install. Instead, facilities will install wet scrubbers, dry scrubbers, or semi-dry scrubbers to control acid gas emissions from industrial boilers. In addition, no consideration was given for facilities that may have zero discharge permits, where it is infeasible to install a wet control device. EPA should re-evaluate its cost estimates for HCl control.

Comment: EPA presents several cost options in the two ERG memos. Option 2E assumes that facilities will not incur costs to comply with the dioxin/furan standards because they will test for dioxin/furan and be below detection levels. This assumption is unrealistic, especially because EPA has not outlined in the rule any procedures for handling non-detects when performing compliance testing and there are boilers in the EPA emissions database with dioxin/furan emissions that are non-detect but actually measured emissions higher than the proposed limit. EPA should re-evaluate its cost estimates for dioxin/furan compliance. More detailed comments on detection limit issues and the dioxin/furan emissions data were presented earlier in this document.

Comment: A single theme lies at the center of our comments on the proposed Industrial Boiler Maximum Achievable Control Technology (MACT) standard — the proposed standards are far more stringent than needed to assure protection of health and the environment from industrial boiler Hazardous Air Pollutants (HAP) emissions. Oberlin College fully supports measures that truly protect health and environment. But Oberlin College, like others, is challenged by the severe economic downturn and aggressive competition from other private and public colleges. None of us can afford to spend limited financial resources unwisely and we urge you to reconsider elements of the Industrial Boiler MACT standards which we believe, in their present form, are complicated and expend limited resources needed for educational and deferred maintenance programs.

Comment: The proposed Industrial Boiler MACT standards are far more stringent than needed to assure protection of health and the environment from industrial boiler HAP emissions. We are committed to operating in an environmentally responsible and sustainable manner. However, as an industry we are facing a withering economic slump and fierce competition from overseas. Therefore, it is imperative for mandatory environmental controls such as the Industrial Boiler MACT standard to be tailored as closely as possible such that health and the environment are protected without requiring unnecessary expenditures of time and resources. EPA has the legal discretion and technical justification to substantially reduce the burden of the standard while still providing ample protection to health and the environment.
EPA can provide reasonable approaches in its final Boiler MACT rule that will improve air quality and target investments strategically, preventing severe job losses and tens of billions of dollars in unnecessary regulatory costs.

Response: See response for DCN EPA-HQ-OAR-2002-0058-1876, Excerpt Number 3.

Commenter Name: Paul N. Cicio
Commenter Affiliation: Industrial Energy Consumers of America
Document Control Number: EPA-HQ-OAR-2002-0058-2752.1
Comment Excerpt Number: 3

Comment: Industry experts estimate that the Boiler MACT will cause significant fuel switching from coal to natural gas and increase demand between .65 TCF to .85 TCF in a relatively short time period. That is a lot of new demand. To put this figure in perspective, according to the EIA, a .65 TCF increase in demand is equal to a 3% increase in national demand and equal to demand levels that the EIA forecasted for 2025. From 1996-2008, natural gas demand increased only 2.81%. As demand increases for natural gas, the price of natural gas and electricity will rise not just for manufacturers, but for all consumers.
The proposed boiler MACT creates emissions standards that are unnecessarily stringent using questionable methodologies that will significantly increase the cost of energy for IECA members. This increase in costs will make the industries less competitive causing some to eliminate their US manufacturing operations. IECA proposes that EPA develop more reasonable standards that are achievable in practice, consistent with Clean Air Act requirements.
IECA believes the EPA has overstepped its bounds. EPA has failed to make a compelling case that such aggressive requirements are necessary within the discretion that the agency has in

setting these standards, result in tangible improvements to health and the environment, and are justified by cost-benefit analysis.

Comment: The economic analysis is clear. Units that recover usable energy from flared coke oven gas should be exempt. The Proposed Rule sets numeric emission limits for 5 pollutants (PM, HC1, mercury, dioxinlfurans, and CO). At this time, coke oven gas-fired units are not controlled for these compounds. Using EPA's projected cost of control (annualized capital cost + annual operating cost) for each pollutant including monitoring, recordkeeping and reporting, we calculated an annualized cost of control at $8.4 million for a single 650 MMBtu/hr combusting coke oven gas. At $5/MMBtu for natural gas, it is economically unreasonable for the boiler operator to use COG to displace the first 1,680,000 MMBtu per year of natural gas in this boiler. This immediately sends COG back to the flare for boilers relying on COG to supplement blast furnace gas combustion. These units would immediately use natural gas to replace COG to the detriment of the environment and our energy policies.company will invest $8.4 million in annualized control costs, it will need to justify a return on the capital investment far greater than $8.4 million in displaced natural gas. Capital investments typically require a return on investment of 2 years or less in the current capital-constrained environment. For the coke oven gas-fired boilers that we operate (<60% COG heat input rate mixed with BFG and natural gas), it is not possible to recover the cost of capital in two years for this project. [Footnote: The capital cost for controlling this model unit is $27,747,000 and the annual operating cost is $5,678,000. Excluding the 10% coke oven gas that could be burned with natural gas in a unit that qualifies for Gas-1 work practices, the annual benefit from displaced natural gas for a Gas-2 unit is $4,337,000, which does not cover the capital invested or controls for over six years.] In fact, the estimated return on investment is more than six years when compared with a baseline case that would not require control equipment. [Footnote: The base case assumes that a unit combusting >90% (Natural Gas + BFG) would qualify for the Gas-I subcategory. If the distinction between Gas-1 and Gas-2 remains in the final rule, EPA must clarify how BFG heat input is to be considered in the subcategory threshold analysis. Currently, a unit burning less than 90% natural gas and less than 90% BFG falls through the regulatory cracks. It is not a unit "designed to burn Gas-1" and it is not excluded as a blast furnace gas fuel-fired boiler. If the 90% natural gas threshold remains for Gas-1, BFG heat input should be counted toward that annual threshold.] The Proposed Rule will also eliminate new projects currently in the pipeline that are designed to use flared COG to displace natural gas because the capital cost to meet Gas-2 emission limits would render these projects economically infeasible.

Response: If units firing COG can demonstrate they meet the specifications outlined in the final rule for H2S and mercury they will be subject to work practice standards in lieu of emission limits. The 90 percent threshold has been removed from the final rule gas 1 subcategory definition, see the final rule for the modified definition.

Document Control Number: EPA-HQ-OAR-2002-0058-1425.1
Comment Excerpt Number: 2

Comment: We are concerned about the increased cost associated with annual testing required under this proposal. This proposed rule would increase the frequency that stack testing is

required by 150%. Even without testing for additional pollutants, this requirement would more than double the current costs for emissions testing.
In addition, the proposed rule would require Sauder to test for additional pollutants. A quote from our stack testing company shows that the annual testing would cost approximately $40,000.00 when including fuel analysis. This is a 30% increase from testing now required under our Title V permit. Given the significant increase in costs related to test frequency and test composition, we request that the frequency and content of testing be re-considered.

Response: See preamble for response.

Comment Excerpt Number: 15

Comment: Production losses will be incurred under the provisions of this rule for process shutdowns associated with the burner tune-up requirements, CPMS calibration requirements, and special, uneconomic operations associated with the performance test requirements that must be done using the worst case conditions. This production related cost must be taken into account in evaluating the proposed rule, not only from a cost perspective, but from a feasibility perspective. For example, annual emissions testing using the worst case fuel mix on all units using a 4-hour test run time will impose tremendous operational constraints on facilities that they may not even be able to meet (e.g., for limited use units or due to lack of availability of the worst case fuel). EPA should add this cost to its burden estimates.

Response: See preamble for response.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 25

Comment: * EPA has estimated a cost of $44,000 to conduct testing for all 5 pollutants. While we believe this might adequately predict the cost of a stack test for some boilers, EPA has not considered scenarios where facilities must test two different operating conditions to represent worst-case mercury and chloride inputs or where they do not have enough of their worst case fuel to complete testing in a 1 or 2 day period. EPA has not considered boilers that have dual stacks in its cost estimates. In this case, the testing cost is almost doubled. In addition, some facilities may have the capability to burn more than or less than 10 percent coal with other fuels on an annual basis, so they may have to test under both scenarios to ensure they can comply with limits under different subcategories. The cost to complete stack tests for PM, dioxin/furan, and CO and fuel analysis for chlorine and Hg was estimated to be $16,000. As the dioxin/furan lab analysis is the most costly element of the stack testing required and eliminating the HCl and Hg testing only removes one sample train and associated stack tester, we do not believe this scenario would be less than half of the cost of stack testing for all 5 pollutants, and would likely be at least $30,000 in stack testing and fuel analysis cost. Even EPA's estimate for the Phase 2 ICR testing was $54,000 for most of the units tested with standard methods. Actual costs experienced by facilities required to conduct that testing were higher than that, with some facilities reporting costs of at least $60,000 for a single series of tests. Facilities will also incur additional costs if ERT reporting is required, as this will be an extra step after producing the hard copy report. EPA should re-evaluate its testing cost estimates.

Response: See preamble for response.

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 26

Comment: The cost and emissions impact memo states that boilers and process heaters designed to burn liquid fuels are expected to conduct annual compliance tests for PM, dioxin/furan, and CO, but comply using fuel analysis for HCl and Hg. As the floor units for liquid fuels are based on uncontrolled light liquid units for HCl and Hg and are theoretically based on the average of emissions achieved by the top 12 percent of liquid units, we do not agree with the assumption that the remaining 88 percent of liquid fueled units will not need controls in order to comply with the HCl and Hg limits, especially since these limits were only based on data from less than 25 boilers. In fact, EPA has data in its own database (see table Data: FuelAnalysis in EPA's database emissions_database_boilers_heaters.mdb) that shows that several facilities burn fuel oil that will not meet the proposed emission limits for HCl or Hg based on fuel analysis.

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 306

Comment: Requiring the ERT will add time and cost to stack testing projects, as time will have to be spent entering the test data into the tool and then quality assuring the ERT output. We do not believe that EPA has included this extra cost in their analysis.

Response: The final rule has retained the ERT reporting mechanism. EPA recognizes that there have been some issues with the use of the ERT and we have worked closely with stakeholders to identify and correct these issues. As with all new systems, there are always transition problems as changes to those systems are implemented. Nonetheless, EPA is committed to electronic compilation and submittal of data as demonstrated by the requirement to report data electronically in the Toxic Release Inventory and greenhouse gas electronic reporting programs. We worked (and continue to work) closely with stack testing companies to set up the ERT and have the ERT process mimic most of their work when producing a final performance test report. We believe that there is a learning curve for using the ERT and it will take a few tests and reports to become proficient in its use. However, as users continue to employ the ERT, the time, effort, and subsequent costs needed to produce, review, process, and extract information from the report will decrease. The extended implementation date into 2012 for use of the ERT will also allow adequate time for users to become familiar with the process and allow us to address most of the concerns by the commenters.

Comment: EPA Incorrectly Estimates the Burden of CO Monitoring. The Proposed Rule 63.7525(a) requires large sources (heat input capacity of 100 MMBtu/hr or greater) to operate a continuous emission monitoring system ("CEMS") for CO and oxygen. EPA justifies its decision to use CO as a surrogate for organic HAP in part because "many sources currently have CO CEMS." 75 Fed. Reg. at 32018. However, while some sources may have existing continuous CO analyzers, these CO analyzers are often ancillary in nature and are not certified CEMS. A requirement for CO CEMS, therefore, will require expensive installation of many new CEMS.

A certified CO CEMS requires a considerable financial investment in both capital and operational costs including daily operation, scheduled maintenance, reporting and recordkeeping, robust spares parts inventory, and the necessary cylinder gas audits and annual RATAs. At the same time, if a source has existing CO equipment, it may be incapable of accurately measuring CO concentrations of 30-90 ppm for purposes of this rule – these units have been commonly available in 0-2500 ppm to 0-10000 ppm full span, which are not appropriate for measuring CO at the levels of the proposed CO standards. These analyzers would either require significant modification or need to be replaced with new CO instruments having the appropriate span range.

Response: See preamble for response.

Commenter Name: Randall D. Quintrell
Commenter Affiliation: Georgia Paper and Forest Products Association, GPFPA
Document Control Number: EPA-HQ-OAR-2002-0058-2905
Comment Excerpt Number: 19

Comment: GP&FPA has facilities with multiple boiler units. At least one facility has 6 boilers that will be subject to the Rule. It is easy to see that trying to schedule such long duration tests and so many tests for potentially 2 or more fuel mixes will quickly become unmanageable especially on a 10 month repeat frequency. The testing would simply never end. This is exacerbated by the need to test at high rates that may not be sustainable over the prescribed long test periods. Also, we have some facilities with a single large boiler. The unit load is entirely dependent on mill steam demand at the time and it cannot be managed to achieve a "maximum" normal over an extended test period without venting steam and wasting valuable fuel. In addition to the logistical issues associated with operating this way, the costs for such operation have not been considered in EPA's testing cost estimates.

There are additional logistical problems related to physical constraints on testing facilities. To run tests for different parameters at the same time, which must be done as a practical matter due to the extended test runs and required load conditions, multiple sampling trains are required. Most sampling platforms were designed for single train testing and the lack of space and port availability can make the testing significantly more difficult. Alternately it requires consecutive tests instead of concurrent testing which multiplies the cost accordingly. This lack of work space is especially critical for the sophisticated tests being conducted under the proposed Boiler MACT requirements, with emissions at or near quantitation limits with very low tolerance for variability. It also slows the testing down. Some sites might be able to increase the platform size but for many stacks, larger platforms may not be feasible. The platforms are often suspended from the stack which cannot support more weight. One mill which has conducted similar tests stated that it was extremely difficult to get more than one run per day even during the long daytime hours of summer and it would be impossible to do so in winter. With setup time, changing ports and testing time, a 4-hour test run consumed at least 6 hours of actual time. The mill ran three scenarios on one unit to cover fuel mixes, so there were 9 four-hour runs required. This mill has a load following boiler with load swings and mill operations had to be considered in loading the boilers during testing. The testing took 2 weeks for this one source. Multiply this by 2 to 6 boilers per facility, as many of us have, and the testing burden quickly becomes extreme.

Commenter Name: Randall D. Quintrell
Commenter Affiliation: Georgia Paper and Forest Products Association, GPFPA
Document Control Number: EPA-HQ-OAR-2002-0058-2905
Comment Excerpt Number: 22

Comment: GP&FPA mills which have recently conducted similar testing (either as part of the 2009 ICR testing or in preliminary testing for internal reasons) have reported a range of costs for the performance testing contractor. The costs have ranged from $65,000 to $90,000 for a single set of tests. No data have been developed for the additional costs of the testing in terms of staff and administrative time, fuel costs and other expenses. Testing contractor costs are expected to significantly increase as demand increases with thousands of boilers required to test in a short time - particularly if the proposed 10 month schedule for retesting is not deleted.

When EPA submitted its ICR proposal to OMB in 2009 for testing of the same basic parameters now proposed as an annual requirement for each non-Gas 1 unit, they estimated the cost for testing 310 units at 16.7 million dollars, or $55,000 per test. EPA assumed 100 man-hours for administrative time per test, to manage and supervise the testing and to review the reports, adding another $6500. That is $65,500 per test per source by EPA's own estimate, which is at the low end of the range of costs our member facilities have actually incurred for Phase 2 testing or preliminary testing. These costs did not include additional fuel costs and other costs to the Mill operation in addition to stack testing contractor costs. Some of our member facilities may have as many as 5 or 6 affected units and many have multiple scenarios to test even with only one unit. For those facilities with multiple boilers and multiple scenarios, the testing costs alone could easily reach $500,000 per required testing episode. These costs do not even include testing costs for the proposed compliance monitoring calibrations and rata testing which are also excessive as proposed. The level of cost for testing as proposed is excessive and unacceptable as a periodic testing requirement and it is an "absurd result" for repetitive testing for all units, some with multiple scenarios, every 10 months!

Response: See preamble for response.

Comment Excerpt Number: 27

Comment: Although the initial Boiler MACT regulation2 required annual testing it adopted the standard 3-hour Method 5 which is a test routinely used by many units for Title V testing purposes. Also, the initial Boiler MACT had more reasonable emission standards, it included the 3-year relief mechanism, and it contained options for alternative fuel sampling and TSM alternative standards. These provisions resulted in a significant but not completely unreasonable testing burden on affected units. In contrast, the testing requirements in the current proposed Boiler MACT are unnecessarily burdensome, punitive, excessively costly, and we believe arbitrary and capricious.

Response: See the preamble for how EPA reduced the testing burden in the final rule.

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 83

Comment: From review of the RIA, it does not appear that the costs and burdens associated with the CO monitoring requirements in the proposed tune-up criteria were fully reflected. If these requirements are maintained and our other recommendations relative to the CO determinations are not implemented, the cost and benefit analyses will need to be corrected to include all of the costs of conducting before- and after-adjustment performance tests for determining stack moisture and oxygen. If it is concluded that use of portable analyzers is not permitted, CO measurement will need to be included as well.

Recommendations: Incorporate all required costs and burdens associated with 63.7540(a)(10)(iv) and (v) into the rule cost and benefit analyses.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2740.2, Excerpt Number 12.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 94

Comment: Attempting to meet the proposed CO limits for Gas 2- and liquid-fired boilers and process heaters will lead to increased NOx emissions and potentially increased PM2.5 and other pollutant emissions depending on the control strategies employed. This could result in making those boilers or process heaters subject to Part 60 subpart D, Db or Dc standards and/or to part 60 subpart Ja and require New Source Review and Prevention of Significant Deterioration analyses and offsets. None of these activities appear to have been addressed in this rulemaking‘s cost or burden analyses or considered in establishing the time needed for compliance. We recommend these impacts be considered as the rule is finalized.

Recommendation: The Agency should make clear in finalizing this regulation that the Part 60 General Provision’s pollution exemption applies to emission increases of criteria pollutants due to modifications associated with complying with this rule, provide a mechanism for extending compliance time where NSR or PSD permitting is needed, and incorporate the cost of that permitting and offsets in the economic and other analyses.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 286.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 135

Comment: Our experience would indicate that EPA's cost estimate is low. CIBO members have paid about $20,000 just for D/F tests that included just 150 minute test runs during the 2009 ICR Phase II testing. CIBO would estimate about $60,000 to conduct the tests for PM, D/Fs, Hg, HCl. The requirement for 4 hour runs would required two testing days instead of one, running up costs considerably for a test, not to mention the logistical difficulties of successfully running a test and working around operational disruptions.

Response: See response for DCN EPA-HQ-OAR-2002-0058-3137.1, Excerpt Number 56.

Commenter Name: Matthew Todd and David Friedman

Comment: As EPA concluded in evaluating where work practice requirements are justified by 112(h), it is quite costly to install platforms and structural facilities to support monitoring stacks. It does not appear from our review of the docket that the Agency cost estimates for CEMS included these costs. In some cases, total stack replacement will be required to allow safe installation, operation and maintenance of the CEMS specified under this rule.

Recommendation: Revise the CEM cost estimates to reflect the costs of stack platforms and access and, in a percentage of cases, stack replacement.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 298.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 161

Comment: The RIA cost and burden analyses included all of the costs burdens, recordkeeping and reporting associated with the QA/QC of parameter and emissions monitors. An effort appears to have been made to include the initial effort associated with developing a monitoring QA/QC plan, but there does not appear to have been any upkeep estimate for that plan or any estimate for the on-going costs and burdens associated with the requirements specified in proposed 63.7525 for all compliance monitors. This is particularly important for CEMS, because the burdens associated with RATA testing are very extensive.

Recommendation: Adjust cost and burden estimates to account for the QA/QC requirements specified in the rule and in the General Provisions and fully account for the RATA testing of required CEMS.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 300.

Comment: Where chloride and mercury controls are in place, annual performance tests are required for chloride and mercury. Separate performance tests for each of these species will be needed in order to test at maximum chloride and mercury as required by the rule, since the maximums usually occur in different fuels. Additionally, the proposal requires that whenever a performance test is performed CO, PM and dioxin/furans be determined. Thus, where chloride and mercury controls are in place (94% of the units with chloride and mercury emission limits), all performance tests should have been estimated on the basis of performing two tests and of testing for all species.

Recommendation: Adjust rule cost estimates and analyses to reflect separate performance tests for any performance test of a unit where chloride and mercury controls are in use.

Response: See preamble for response.

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 173

Comment: Proposed 63.7515(b) through (d) provide for exceptions to the annual testing requirement if emissions do not exceed 75% of the emission limit after three stack tests. However, these provisions do not apply to dioxin/furan monitoring, so they provide no real relief, since a large part of the cost for a stack test is the set-up (including operational setup) and the flow, oxygen and moisture testing. Sources with emissions limits will still have to stack test annually and will have to disrupt operations to bring the boiler or process heater to stack test conditions.

Recommendation: Assure that cost estimates and regulatory analyses reflect the requirement to annually test for dioxin/furans at all units and that the costs and burdens associated with that testing are valid.

Response: See response for DCN EPA-HQ-OAR-2002-0058-3137.1, Excerpt Number 56.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 221

Comment: The cost and burden estimates fail to address the large effort that will be associated with permitting all of these changes and performing the New Source Review analyses required because of the increases in criteria pollutants that will result from this proposal. Similarly, while the rule supporting estimates incorporate a small amount of time for an initial reading of the regulation, they include no costs or burdens for ongoing training or for the massive effort associated with incorporating these new requirements into site compliance programs, both initially and as new boilers and process heaters are added.

Recommendation: Adjust the cost and burden estimates for the permitting and compliance system modification costs necessary for achieving compliance with this rule.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 286.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 222

Comment: The rule cost and burden analyses fail to account for the large effort associated with managing unit outages and special operations to conduct the required tune-ups and performance tests. In some cases, boilers and process units will have to be shutdown to allow burner inspections or to make repairs resulting from the inspections. In all cases, the annual tune-up and performance testing will require operating the boiler or process heater at specific high rate conditions and often with unusual feeds to meet the requirement for maximum mercury and chloride in the feed during performance tests. Significant engineering effort will be required to manage these special operations, particularly for process heaters which typically are not spared and thus the entire process will have to be run non-optimally.

Recommendation: Adjust cost and burden estimates for the engineering and operational efforts needed to accommodate the proposed tune-up and performance test requirements.

Comment: [See submittal for TABLE 1-2. COMPARISON OF API AND EPA COST IMPACT ESTIMATES FOR GAS 1 ($/YR)]

The total annual cost impact of compliance for Gas 1 with BPH NESHAP emissions limits is approximately $13.6 billion, approximately 80 percent higher than EPA's cost estimate of $7.6 billion. The difference in costs are primarily due to underestimated costs associated with pollution control upgrades (discussed above) and with testing and monitoring requirements.

The total annual estimated cost impact of compliance is approximately $0.87 billion, approximately 88 percent higher than EPA's cost estimate of $0.46 billion.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 301.

Commenter Name: Matthew Todd and David Friedman

Comment Excerpt Number: 277

Comment: [See submittal for TABLE 1-2. COMPARISON OF API AND EPA COST IMPACT ESTIMATES FOR GAS 1 ($/YR)]

EPA significantly underestimated the total cost of stack testing and monitoring for Gas 1 by approximately $700 million annually. Although EPA slightly underestimated stack testing costs on an individual per BHP unit basis, the reason for such a dramatic cost differential for the entire Gas 1 subcategory is unclear. Based on information received from an API member company, EPA's estimates for continuous emissions monitoring (both initial setup and annual costs) were significantly underestimated.

EPA significantly underestimated the total cost of stack testing and monitoring by approximately $8 million annually for the same reasons cited for the Gas 1 subcategory.

Comment: MAJOR AND MINOR NEW SOURCE REVIEW (NSR) PERMITTING

In addition to the significant costs associated with companies developing compliance strategies for the BHP (also not addressed in this report), addition of new pollution control technologies and "optimization" of carbon monoxide (CO) controls can notably increase emissions of certain other criteria pollutants, which may necessitate costly and potentially problematic permitting actions. Increased emissions can result from the following:
* Reducing CO emissions to low concentrations often increases nitrogen oxides (NOx) emissions;
* Operation of catalytic oxidation controls for CO control will result in additional fuel combustion, which increases emissions of all combustion related compounds including carbon dioxide (CO_2);
* Operation of catalytic oxidation controls for CO control will result in additional particulate matter (PM) and sulfuric acid mist (SAM) emissions as sulfur dioxide (SO2) emissions are oxidized to sulfur trioxide (SO3), which converts to SAM (which is also particulate matter);
* Certain Gas 2 streams at refineries will have to be treated to remove hydrogen sulfide (H2S) emissions, resulting in higher SO2 emissions (it is our understanding that API is providing a more detailed discussion of this ramification).

The quantities of pollutants and the permitting ramifications on individual facilities are difficult to quantify because they will vary considerably based on site-specific situations. At a minimum, minor NSR permitting is required for the installation of pollution control technologies, and frequently these permitting exercises are not trivial because they can require extensive state-driven air dispersion modeling evaluations. There are a number of conceivable scenarios in which major NSR permitting could also be triggered at a site, resulting in costly and lengthy permitting efforts which may include ambient air quality impact analyses as well as application of best available control technology (BACT) or even lowest achievable emission rate (LAER). Trinity is already seeing significant complications in permitting actions due to increasingly more stringent air quality standards recently promulgated (and soon to be promulgated) by EPA. Regardless of whether minor or major NSR is triggered, there will undoubtedly be thousands of significant permitting activities across the U.S. that would be triggered due to compliance with the BPH NESAHP requirements. Such projects will involve not only significant internal and external resources for permitting, but could also require modification of plant layouts or process operations in order to comply with air quality standards.

Response: See the discussion in the preamble for changes made to CO limits and compliance requirements. EPA made several changes to incorporage measurement error and consider CO variability over various boiler loads and determined that these changes can mitigate the concerns with increased NOX emissions. EPA has also provided an estimated in the impacts section of the preamble for increased CO_2 emissions from the energy consumption used by control devices such as oxidation catalysts. EPA has also modified the definition of gas 1 to be more inclusive of gaseous fuels that can demonstrate they meet the specification for H2S and Hg. See response to comment EPA-HQ-OAR-2002-0058-0851.1, excerpt 7 for the costs of the NSR program which are not estimated as part of this rulemaking.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 292

Comment: EPA's estimated cost for the full testing program for PM, HCl, Hg, CO, and dioxin/furan are generally reasonable for single-fueled sources. However, the $7,000 reduction for the elimination of CO from the stack testing program for 100 MMBtu/hr units is overestimated. The addition of a CO to a test program that already includes the cost of mobilization would only require an additional analyzer to the setup and possibly an additional test technician. Given the low cost associated with adding CO to a test program, a $3,000 reduction from the full test scenario would be more appropriate.

Response: See preamble for response.

Commenter Name: Matthew Todd and David Friedman

Comment Excerpt Number: 295

Comment: EPA's assumption that all BPHs equal to or greater than 10 MMBtu/hr are equipped with test ports and scaffolding is inappropriate.

Response: See preamble for response.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 296

Comment: The revised cost estimates associated with stack testing of gas-fired sources are presented in Tables 3- 1 and 3-2, respectively. [See submittals for tables.] It was assumed each unit would be required to demonstrate compliance through stack testing on annual basis for all pollutants with the exception that units equal to or greater than 100 MMBtu/hr would not test for CO because these units would be equipped with a CO CEMS.

API estimates include costs for scaffolding and test ports for all units less than 10 MMBtu/hr. The percentage of units 10 MMBtu/hr or greater needing test ports and test platforms is unknown; however, it a conservative estimate of 25% of BPHs between 10 and 100 MMBtu/hr was included in the total annual cost for these units.
[See submittal for TABLE 3-2. COSTS FOR ANNUAL TESTING OF GAS 1 SOURCES ($)]
Cost for stack testing based on EPA's estimate for PM, HCl, Hg, CO, and dioxin/furan with the exception of
sources greater than 100 MMBtu/hr where a $3,000 reduction was assumed for the elimination of CO from the test program.
Cost for test ports estimated to be 11,000 per source and an additional 14,000 per source for temporary scaffolding.
Cost for ports and scaffolding annualized based on the following:
Interest Rate: 7%
Years: 5
Assumed that 25% of BPHs in the 10 - 100 MMBtu/hr size category do not have existing scaffolding or test ports.
Assumed $2,000 for electronic data entry.

[See submittal for TABLE 3-3. COSTS FOR ANNUAL TESTING OF GAS 2 SOURCES ($)]

Response: See preamble for response.

Comment: CEMS PLANNING COSTS

The costs associated with the purchase, installation, and operation of CEMS is a significant capital expenditure for any facility. Given this significant expenditure, and the critical nature of CEMS design for obtaining reliable and representative data, the planning phase of such projects requires a significant amount of engineering and design work. In comparison to actual costs incurred by its members on CEMS installation projects, API has found EPA's cost estimates for planning activities to be significantly underestimated. For example, API has estimated the planning phase for the installation of a new CEMS to be as much as 40 times higher than EPA estimates.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 300.

Comment: CEMS SUPPORT FACILITY COSTS

As EPA concluded in evaluating where work practice requirements are justified by 112(h), it is quite costly to install platforms and structural facilities to support monitoring equipment on stacks. It does not appear from our review of the docket that EPA cost estimates for CEMS included these costs. In some cases, API expects that total stack replacement may be required to allow safe installation, operation and maintenance of the CEMS specified under this rule. Unlike the temporary nature of stack access required for annual testing events (which can be accommodated with rented scaffolding equipment), stack ports used for continuous monitoring equipment must be accessible at all times to ensure continuous and reliable operation and to facilitate preventative maintenance and routine calibration activities. EPA's cost estimates associated with certain aspects of support facilities (e.g., installation of sampling ports, utilities, platforms and ladders, and a climate-controlled instrument/analyzer shelter) appear to be significantly underestimated. For example, API has determined the cost for the support facilities related to installation of a CO CEMS at nearly 15 times higher than EPA estimates. API's estimate is based on actual project costs to install such systems, and includes the costs for stack modifications (addition of ports and access platforms) as well as the installation of a climate-controlled shelter for housing the CEMS.

Response: See preamble for response.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 299

Comment: CEMS INSTALLATION AND STARTUP COSTS

The cost associated with the initial installation of a CEMS includes not only the design and installation of the system, but also initial startup and troubleshooting activities as well as operator training. For a CO CEMS, API estimates that initial costs for installation would be more than ten times higher than EPA has estimated.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2960.1, Excerpt Number 300.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 300

Comment: ANNUAL COSTS

Annual costs associated with operation, maintenance, repairs, and QA/QC of CEMS include activities such as the daily activities associated with calibrations and monitor operation as well as annual Relative Accuracy Testing Audits (RATAs) testing, quarterly cylinder gas audits (CGAs), record keeping and reporting, the annual review of QA/QC Monitoring Plans and Operation and Maintenance Plans.

For overall annual costs of operating and maintaining a CEMS, API estimates costs that are approximately three times higher than EPA's estimates. API's cost estimates account for the cost of skilled instrument technician labor for daily calibration and routine maintenance and operation of the CEMS, as well as the cost of quarterly CGAs and annual RATAs, plus on-going review and updates to CEMS QA/QC monitoring plans and procedures. These costs also take into account the significant labor investment that is required to ensure that the CEMS operates with minimal downtime, undergoes periodic preventative maintenance, is supplied with adequate spare parts, and receives software updates and other upgrades as needed.

Response: See preamble for response.

Commenter Name: Matthew Todd and David Friedman

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 301

Comment: API's revised cost estimates associated with monitoring requirements of the proposed rule are outlined in Table 4-2, Table 4-3, and 4-4 [See submittal for tables.]. These costs assume the same number of affected units that EPA used in their cost estimates. [Footnote: It should be noted that the number of affected units used in EPA's monitoring cost estimates were not clearly supported.] As discussed previously for other aspects of EPA's cost analysis for this rule, the affected units are based on the Gas 1 and Gas 2 source categories assumed to be conservatively low based on the additional sources believed to be subject to the rule but not included in EPA's calculations. It should also be noted that EPA's costs for parameter monitoring systems (BLDS, scrubber parameters, and ACI) on a per unit basis appear to be generally reasonable. However, it should be reiterated that API believes EPA has significantly underestimated the number of sources that would need to install pollution control devices to meet numerical limits in the proposed rule, which would also mean that costs associated with parametric monitoring of those control devices is also significantly underestimated. The revised cost estimates provided in this report assume the parametric monitoring system costs would be part of the capital costs of the control equipment and therefore are not addressed in this section of the report.
The revised cost estimates for CEMS included in the tables below are based on typical project costs obtained from actual projects by API members for both the initial costs and annual operating costs. API has estimated per unit CEMS monitoring costs as follows:

[See submittal for TABLE 4-2. API MONITORING COST ASSUMPTIONS PER UNIT]

When API's per unit costs shown above are then applied to the affected source counts used by EPA in their monitoring cost analysis, the total costs of compliance with the monitoring requirements of the rule are significantly higher than what EPA has estimated. The following tables show the comparison of these revised costs to EPA's estimated costs for total initial costs (TIC) and total annual cost (TAC) with capital recovery for both the Gas 1 source category as well as the Gas 2 source category.

[See submittal for TABLE 4-3. COMPARISON OF MONITORING COSTS FOR GAS 1 SOURCES ($)]

[See submittal for TABLE 4-4. COMPARISON OF MONITORING COSTS FOR GAS 2 SOURCES ($)]

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 29

Comment: EPA acknowledges that PM CEMs will cost an average of $88,000 per unit, annualized to $33,000 per unit. For a municipal utility like the City of Orrville that operates four boilers this size, these costs can quickly exceed a quarter of a million dollars. This is a significant cost burden, particularly for small entities that may already be required to spend millions on control equipment to comply with proposed emission limits. Yet EPA has provided no justification for imposing this additional cost.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2875.1, Excerpt Number 7.

Document Control Number: EPA-HQ-OAR-2002-0058-2937.1
Comment Excerpt Number: 37

Comment: FID analyzers utilize flame ionization technology to continuously measure total hydrocarbons in a variety of gaseous sample matrices. FID analyzers are basically carbon counters and can measure accurately from single-digit ppm to low percent levels of hydrocarbon concentrations. FID technology is accepted as a method of choice for total hydrocarbon measurements and meets EPA method 25A for compliance monitoring and 1065 for automotive testing requirements. The cost for an FID analyzer for THC is about $13,000. For both methane and non-methane THC, its about $17,000.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2740.2, Excerpt Number 12.

Commenter Name: Ann W. McIver
Commenter Affiliation: Citizens Energy Group
Document Control Number: EPA-HQ-OAR-2002-0058-2875.1
Comment Excerpt Number: 7

Comment: In the preamble discussion, EPA suggests that the initial capital cost for PM CEMs monitoring is estimated to be $88,000 per unit. In order to understand EPA's estimated costs in the context of our facility, Citizens contacted vendors with experience in the installation and operation of continuous emissions monitoring equipment, including PM CEMs. These vendors provided budget estimates for the installation at a site equipped with data acquisition system equipment (needed to manage the data), as well as a location with sufficient stack access to the equipment.

Depending on whether the facility has a dry or wet stack, the procurement and installation of the PM CEMs ranges from $55,000 to over $100,000, which may be represented by EPA's estimate of $88,000 per unit. However, in addition to the equipment, there are additional costs that must be factored in, including data acquisition and management, and initial certification costs.

The estimated cost for the installation of the data-management side, including configuration of a data acquisition system to manage the data produced by the CEMs, exceeds $10,000, and estimates for the initial certification testing of the CEMs range from $30,000 to $50,000. These costs may add an additional $40,000 to $60,000 to the capital costs. Additionally, for facilities lacking existing infrastructure for CEMS, the addition of a stack platform, access, GEMS shelter, and utilities can easily exceed $100,000 per stack.

While Citizens has not reviewed the background data used by EPA, we believe that the cost estimates that form the basis of the proposed rule may be lower than facilities are likely to encounter.

Response: See preamble for response.

Comment: It is not clear that the EPA has adequately accounted for the total costs of controls, including not only capital costs but also ongoing operation and maintenance costs of, for example, PM CEMS and CO CEMS. IDEA encourages EPA to consider the use of parametric monitoring, including opacity and bag-leak detection equipment, in lieu of the PM CEMs as a compliance monitoring tool.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2875.1, Excerpt Number 7.

Comment: Our experience from conducting ICR Phase II testing indicates that EPA's cost estimate is too low. It is estimated that about $60,000 is the cost to conduct the tests for PM, D/Fs, Hg, HCl. Given that the proposed rule requires annual testing and 4-hour runs, it will create a significant burden due to the expense of testing and operational disruptions associated with testing periods.
A performance testing frequency of once per Title V permit term, or every 5 years which is consistent with current permit obligations, would be sufficient to demonstrate compliance with the emission standards.

Response: See response for DCN EPA-HQ-OAR-2002-0058-3137.1, Excerpt Number 56.

Comment: CEMS will be excessively costly to implement. For facilities with multiple sources, numerous new monitoring and compliance systems would be required, which will place a significant economic burden on the facilities' operation. EPA is required to take cost into account in its procedural regulations. 42 U.S.C. § 7412(d)(2)). While EPA provides an estimate for the cost of implementing a PM CEMS system, it does not explain how it obtained that number. Nor did EPA provide any analysis regarding the economic impact of the cost of installing and running CEMS systems on multiple sources. EPA merely states the proposal would be reasonable for sources with a high heat input capacity. However, heat input capacity has no connection with a company's economic stability or its ability to absorb significant additional operating costs.

Beyond its faulty cost analysis for PM CEMS, EPA provides no costs for CO CEMS, opacity monitoring, pH, pressure drop, liquid flow rate, sorbent injection rate, bag leak detection, secondary current and voltage, total power output, or any of its other mandatory compliance and monitoring measures. EPA is required to consider the costs of these systems but has failed to comply with that regulatory mandate.

Response: See preamble for response.

Comment: GPI — Macon Mill has obtained a preliminary estimate of $65,000 for performance testing of the required pollutants for the existing biomass boiler at the Macon Mill. This represents cost for just one boiler and one fuel operating scenario (which may not be sufficient for multi-fuel boilers). Beyond the actual stack test costs from the testing firm, there are additional costs that the Macon Mill will have to absorb associated with the proposed requirements:

GPI — Macon Mill estimates potentially tripling annual stack testing costs.

Significant increase in time necessary for testing, potentially moving from one week of stack testing for existing requirements to at least two and potentially three weeks, depending on the number of fuel scenarios required for multi-fuel units. During this testing time, mill production operations can also be impacted.

During testing for the existing biomass boiler, a significant amount of coal may be required if required to combust 100% coal. This represents a substantial cost for fuel relative to normal operations simply for the purposes of testing. This also translates into additional costs for usage of caustic on the existing biomass boiler, which is only employed when combusting coal.

At least one additional operator is required during testing to oversee mill and boiler operations. Given the anticipated timing for testing, we expect overtime costs will increase by two to three times.

Comment: EPA has significantly underestimated the cost of conducting annual performance tests when evaluating the impact of the proposed rule. [Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters, April 2010, page C-6]

Based on recent stack test programs conducted at several IP facilities, we believe that EPA's estimate of $44,000 annual Boiler MACT stack tests should be doubled. In response to EPA's 2009 CAA Section 114 request, we performed hazardous air pollutant emissions stack test programs on boilers at 7 different pulp and paper mill locations. As would be reasonably expected, the complexity and cost of seven test programs varied based on factors such as accessibility of stack and fuel sampling locations, the distance contract test crews had to travel to the site, and the site's ability to base load the steam generation rate of the tested boiler to maintain steady operations over the span of the test periods. From this test program, the average cost associated with sampling, analyzing and reporting Boiler MACT emissions (Dioxins/Furans, Mercury, Hydrogen Chloride, Particulate Matter, Carbon Monoxide) and fuel characteristics was $85,000 per boiler for a single operating scenario (operating rate and fuel mixture). Because many of the boilers used in the Pulp and Paper Industry are designed to burn multiple fuels, many boilers will require testing under more than one operating scenario.

Comment: EPA's proposed rule underestimates the cost of installing CO CEMS.

The cost estimate for CO CEMs provided in the Supporting Statement for the NESHAP for Industrial, Commercial and Institutional Boilers and Process Heaters at Major-Source of HAP12 is grossly underestimated. The estimate provided in this document was approximately $163,000 (total capital investment) per unit. However, based on our own estimates, this value is over $800,000. Below is a comparison of the itemized cost listed in Appendix J-2 of the CO cost estimate versus the commenters estimated cost. (see submittal for cost comparison table). :

Adjust the estimated costs for the CO CEMs installation and reevaluate its justification.

Comment Excerpt Number: 135

Comment: Production losses will be incurred under the provisions of this rule for process shutdowns associated with the burner tune-up requirements, CPMS calibration requirements, and special, uneconomic operations associated with the performance test requirements that must be done using worst case conditions. This production related cost must be taken into account in evaluating the proposed rule, not only from a cost perspective, but from a feasibility perspective. For example, annual emissions testing on all units using a 4 hour test run time will impose tremendous operational constraints on facilities that they may not even be able to meet. EPA should add this cost to its burden estimates.

Response: See response for DCN EPA-HQ-OAR-2002-0058-3213.1, Excerpt Number 15.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 146

Comment: EPA has estimated a cost of $44,000 to conduct testing for all 5 pollutants. While we believe this might adequately predict the cost of a stack test for some boilers, EPA has not considered scenarios where facilities must test two different operating conditions to represent "worst case" mercury and chloride inputs or where facilities do not have enough of their "worst case" fuel to complete testing in a 1 or 2 day period. The cost to complete stack tests for PM, dioxin/furan, and CO and fuel analysis for chlorine and Hg was estimated by EPA to be $16,000. As the dioxin/furan lab analysis is the most costly element of the stack testing required and eliminating the HCl and Hg testing only removes one sample train and associated stack tester, we do not believe this scenario would be less than half of the cost of stack testing for all 5 pollutants, and would likely be at least $30,000 in stack testing and fuel analysis cost. Even EPA's estimate for the Phase II ICR stack testing assumed $54,000 for most of the units tested with standard methods. Facilities required to conduct that testing found the costs to be considerably higher, with spot reports of at least $60,000 for a single series of tests. EPA should reexamine its estimated stack testing costs.

Response: See response for DCN EPA-HQ-OAR-2002-0058-3213.1, Excerpt Number 25.

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 147

Comment: The Cost and Emissions Impact memo states that boilers and process heaters designed to burn liquid fuels are expected to conduct annual compliance tests for PM, dioxin/furan, and CO, but comply using fuel analysis for HCl and Hg. As the floor units for liquid fuels are based on uncontrolled light liquid units for HCl and Hg and are theoretically based on the average of emissions achieved by the top 12% of liquid units, we do not agree with the assumption that the remaining 88% of liquid fueled units will not need controls in order to comply with the HCl and Hg limits, especially since these limits were only based on data from less than 25 boilers. In fact, EPA's database that shows that several facilities burn fuel oil that may not meet the proposed emission limits for HCl or Hg based on fuel analysis. EPA should re-evaluate its compliance cost assumptions for liquid fuel boilers for HCl and Hg.

Response: The final rule allows any unit, not just units without controls, to demonstrate compliance with the applicable emission limit for hydrogen chloride or mercury using fuel analysis if the emission rate calculated according to §63.7530(c) is less than the applicable emission limit. We included estimates of control costs for all liquid fuel units where the estimated baseline emissions exceeded the MACT floor.

Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 5

Comment: The proposal preamble also reports that EPA has been unable to estimate the benefits of any HAP reductions that might be achieved by these requirements and thus they argue that the societal benefits of this proposal come from estimated reductions in criteria pollutants, in particular particulate matter (PM) reductions. It is a significant and questionable shift for the EPA to attempt to justify regulations under HAP reduction authority on another basis than HAP reductions. The CAA provides different authorities and different procedures for addressing criteria pollutants and HAPs. Congress established separate procedures to allow optimization of the requirements addressing these very different types of pollutants and to minimize the disruption to the economy by applying inappropriate approaches to each. Basing HAP rules on their estimated criteria pollutant impacts circumvents Congress's intent and the procedures for addressing criteria pollutants established by the CAA. The benefits associated with criteria pollutant reductions have already been claimed under the NAAQS rulemakings and procedures and it is inappropriate to claim the same benefits again. The benefits that EPA claims for fine PM reductions are highly uncertain and significantly over-estimated. [This issue is discussed at length in the American Chemistry Council Comments on EPA's Proposed Rule National Emissions Standards for Hazardous Air Pollutants From the Portland Cement Manufacturing Industry 74 FR, May 6, 2009, Submitted September 4, 2009 to Docket EPA-HQ-OAR-2002-0051.]

Response: EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. Co-benefits that occur as a result of a regulatory action are appropriate to include in the regulatory impact analysis, and it is appropriate to compare the total monetized benefits with the costs.

Comment: Use EPA discretion to protect public health while avoiding unnecessary capital and operating costs. The estimated costs for the wood products industry, for the installation of control devices, is $6- to $7 billion. We must ensure that the benefits derived from this expenditure are real, and not just estimates by a panel of experts who vary widely on their estimates of benefits.

Response: The primary benefits estimates are derived from epidemiology studies examining two large population cohorts: the American Cancer Society cohort (Pope et al., 2002) and the Harvard Six Cities cohort (Laden et al., 2006). These are logical choices because both studies are well designed and peer reviewed. In addition, EPA estimated the range of benefits derived from an expert elicitation to characterize the uncertainty in the concentration-response function for premature mortality (Roman et al., 2008). In general, benefits estimates derived from the expert elicitation functions fall between results using the epidemiology studies.

Comment: It has always been my experience that the EPA doesn't take into account -- when the developing standards, they don't take into account costs, that --
the costs that have to be made. However, since it has
been brought up consistently throughout the day, I would
like to add to that discussion; birth defects, asthma,
bronchitis, heart attacks, cancer, premature death.
These are some of the outcomes of being exposed to the
air toxins that have been previously discussed, and I
would like to see how much that costs. There is a cost
associated with that.
Last week, I was asked to go visit a young
mother on the east end who lives next to a source that
has already been cited for releasing some of the toxins
previously mentioned. Because I spoke Spanish, they
asked me to go talk to her and try to explain to her why
her child was born with half a brain and suffered for
six months and died. I really didn't have an answer for
that.
All I could do was share her – her concern. She was also -- she was extremely upset, and I'd like to know how much that's worth. It was very
difficult speaking with her, her trying to take care of
her family, and still having two other children figuring
out how -- what she was going to do living next to -- to
the source, and if anybody was gonna do anything about
it. I didn't know what to tell her, but it did prompt
me to come and give a few comments today.

Response: EPA agrees that exposure to fine particulates and toxic air pollutants is associated with severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment Excerpt Number: 10

Comment: In addition to the capital costs, EPA also estimates the "social costs" (e.g., those costs accruing to consumers and producers because of higher prices and diminished trade position). For example, the cost to the chemical industry will be about $500 million in 2013. EPA assumes that producers that comply with the boiler MACT will be able to pass along a quarter of the cost increase via higher prices. Because many products manufactured in the US face stiff global competition, it will be difficult to pass through costs except during times when the market is tight. EPA acknowledges that this will make US exports less competitive and provide opportunities for relatively less expensive imports, but their modeling shows these impacts to be modest (for example, a 0.02% gain in chemical imports and a 0.02% decline in chemical exports). Because many basic building block chemical products potentially affected by the Boiler MACT proposal do not have huge trade volumes (i.e., chlorine, ethylene, etc.), we do not believe EPA considered the subsequent impact in the derivative products that are most exposed to trade. If supply chains are disrupted, this could significantly amplify the impact.

Response: EPA acknowledges the comment, but the commenter did not provide specific information that could be used to conduct the suggested analysis.

Commenter Name: Matthew Todd and David Friedman

Comment: It seems clear that there is little potential HAP reduction from a very high cost unfocused energy assessment program.

The EPA analysis attempts to justify the energy assessment requirements by citing the potential PM reductions that would presumably be achieved along with the HAP reductions. However, PM is regulated by section 110 of the CAA and has been addressed and is being readdressed under the process established by that portion of the Act. Should PM reductions be needed from boilers and process heaters that must be and is being addressed under the 110 authority and should not be a significant consideration here.

Recommendation: The energy assessment requirements should be deleted from the final rule.

Response: The final rule retains the energy assessment requirements. See the preamble for discussion of the final energy assessment. Refer to the RIA for a discussion of how criteria pollutants were used to estimate the benefits of this rulemaking.

Comment: The Regulatory Impact Analysis Should Include a Longer Time Horizon

EPA's regulatory impact analysis presents monetized benefits and annualized social costs for the year 2013 alone. Annualized social costs are based on estimates of annualized engineering-based compliance costs. Benefit estimates are based on emissions reductions in 2013 alone. Capital costs appear to be annualized over the life of the relevant investment at a 7% interest rate (20 years for major equipment, 2 or 4 years for items like fabric filters). The energy assessment is annualized over 5 years (although no justification is given for this). While this is an appropriate method for determining costs and benefits for 2013, it ignores several important longer-term issues.

For example, shutdown of existing units and increased numbers of new units are not accounted for. Shutdown of existing units due to the program would count as additional decreases in emissions and increased costs. Shutdown of units due to independent factors would not directly count as incremental decreases in emissions; however, this would result in spreading the compliance costs of these units over fewer years and fewer reduced emissions, and thus decrease the cost-effectiveness of the program. By contrast, the number of new units over time would probably add net benefits to the rule.

In addition to these sorts of effects, the short time horizon for the regulatory impact analysis ignores future cost decreases due to both innovation and learning, effectively freezing the cost estimates at current technology costs. With technological innovation, economies of scale, and learning, compliance costs may decrease with time. [Footnote: For example, fabric filters may cost $X right now, last two years, and generate $Y/year benefits. But as the regulation increases market share for the filters and incentivizes innovation, as the manufacturers learn more cost-effective filter production techniques, and as the polluters learn more cost-effective filter application techniques, in future years, maybe filters will only cost $1/2X and last for three years, but still generate $Y/year in benefits (or, possibly, $2Y, if the technology improves or if new applications have unexpected co-benefits).] Both the White House's Office of Management and Budget and the EPA's own Economic Analysis Guidelines stress the need to account for technological innovation and learning effects. [Footnote: WHITE HOUSE OFFICE OF MGMT. & BUDGET, CIRCULAR A-4 at 34 (2003); EPA, 240-R-00-003, GUIDELINES FOR PREPARING ECONOMIC ANALYSIS at 5-7(2008 external review draft).] In particular, the OMB's Circular A-4 advises agencies: "The time frame for your analysis should cover a period long enough to encompass all the important benefits and costs likely to result from the rule." [Footnote: CIRCULAR A-4, supra note 50, at 15.] Due to the short time horizon of its regulatory impact analysis, EPA may have underestimated the net benefits of various alternative policies.

Response: The timeframe for this analysis is consistent with other recent EPA analyses. For this rule, the net benefits far outweigh the costs even with several unquantified benefit categories.

Comment: API/NPRA members have oil-fired boilers and heaters located in Hawaii, Alaska, and U.S. island territories, areas that do not have gas supplies available, where the option of switching to a different fuel does not exist. The overly stringent proposed standards for oil-fired units will likely mean that a number of existing boilers and heaters will have to be replaced with new units due to the infeasibility of retrofitting existing units with pollution control devices capable of achieving the proposed standards. We are operating in a business climate in which our members are evaluating their operation assets to determine whether they will remain economically viable. A regulatory mandate for significant capital investment to replace equipment and install new controls could well contribute to a decision to simply shut down some facilities.

Response: Standards have been revised, and a subcategory for non-continental liquid-fired units has been added to address some of the unique constraints faced by operators of these units.

Comment: I am an employee of Flambeau River Papers in Park Falls, Wisconsin, and I am very concerned that the new Boiler MACT rules could cost me my job. We are a small company that is struggling to compete against foreign competitors and large corporations. Our mill not only supports me and my family, it is the lifeblood of our rural community. If the cost of compliance for the Boiler MACT causes our mill to shut down, this entire region in Northern Wisconsin will suffer.

In 2006 our mill was shut down for several months. At that time it was difficult for most people to find good jobs. Now, with the current state of the economy, loosing even more good paying manufacturing jobs would be devastating. Also, if our mill is shut down, the paper that we produce will more than likely be replaced in the market by foreign manufactures who are not held to high environmental standards.

Comment: I am a member of the Chequamegon School District Board of Education, and I am concerned about the impact of the proposed Boiler MACT rules on the education of the students in our school district. The Chequamegon School District is located in rural Northern Wisconsin. The economy in our community is supported by Flambeau River Papers, which employees over 300 people, and impacts hundreds of other jobs in the region.

If the Flambeau River Papers mill cannot afford to comply with the Boiler MACT rules, or is not able to comply because the limits are unachievable, the mill will end up going out of business. If this happens, many families will end up moving out of the area, because there are not enough jobs available to cover this loss. This will result in our school seeing a significant decline in student enrollment, which will significantly reduce our state financial aids. School districts across our state already have to make cuts to stay afloat. If our state aids are decreased even more, we will be forced to make significant programming cuts. Because of this, the education of the students left in our district is going to suffer.

I am sure that this scenario will play out in many communities across the nation. Please consider that the impact of these regulations reaches much further than just "cleaning up the environment." None of us want our children breathing "bad" air. However, please consider the emotional and psychological stress that a child goes through when their parents lose their jobs. Also, consider the impact on the children who are left in a community that was once supported by a strong, good paying manufacturing facility.

Comment: My family is currently employed at Flambeau River Papers LLC in Park Falls Wisconsin, and I am very concerned that Boiler MACT would substantially increase compliance costs for our mill and could put my job and my coworkers' jobs at risk and the community that relies on these jobs – at risk. Our mill has firsthand experience with a closure as it was closed for several months in 2006 with devastating impacts not only to those of us that lost our jobs but also to the local economy. You can clearly see in the workers eyes as they worry about their families and what's next after a life at the mill. Other good paying jobs are hard to find in our rural communities so the harm lasts a long time if not forever. Not only will the town suffer but outreached communities that supply wood to the mill such as loggers and saw mills.

My family lives near the mill and I want them safe, don't get me wrong. Over the years, I have seen the mill get much better environmentally by making changes for the good. The mills new ownership is definitely for a better environment. Equipment and practices we have are helping make us a greener facility in our community. Also, I'm proud to work at a mill that produces a green product that is made from local renewable forests. You go in stores these days and it's hard to find things made in America anymore – we need American products supporting good manufacturing jobs.

Comment: I am writing this in response to the proposed rules for major source Boiler MACT. The rules you are proposing are not achievable. It will cause great hardship to our industry and most likely cause the closure of many sawmills. In Florida alone, the estimate for capital expenditures in the forest products industry is over $170,000,000. We are located in rural small towns in the panhandle of Florida and soon rural Mississippi. The closure of our plants will be devastating on each of these local economies, losing over 125 jobs per location, that is a total loss of 375 jobs. Small towns need these jobs. We are one of the few manufacturing industries that still successfully operate in the United States, is the point to get rid of us too?

Comment: Our initial evaluations of the proposed rules indicate the cost impacts will be a serious challenge to most of the current running mills. The cost impacts hit just as the economic conditions might otherwise allow facilities that currently are shut down to restart. For example, extreme costs may prohibit restarting some of our wood-product facilities that were curtailed due to impacts of the recession on the housing market. This result -- this result would be opposite to the administration goals of rebuilding jobs. It would be a devastating blow to the families and the communities dependent on these facilities.
In fact, to give these costs some scaled perspectives, the Wood Products Council, in which we are members, compiled a projected cost to comply with the proposed rules for some 34 broilers at forest product industry facilities in the State of Mississippi where my mill is located. Those costs projections totaled $290 million. And incredibly, that amount is more than a quarter of the total forest product industry's profits in 2008 and 2009 in the U.S.

Comment: In our area in Alabama where it's 16.4
percent unemployment, and in Mississippi, we're at
12.3 percent unemployment. We survived, Scotch Plywood
did, and we have rehired and we're back in full
production. We contributed to the safe -- we think --
environmental responses in a responsible manner. We
have complied with the plywood MACT and now we're faced
with the Boiler MACT.
Our estimate of costs is going to be
somewhere in excess of $2 million to comply as the
Boiler MACT is presented today. Waynesboro, Mississippi
will have to spend around a half a million dollars and
increase our costs -- our guess, best guess -- is two
and a half percent. That doesn't seem like much.
That's a small number, two and a half percent, but our
margins are small, and nonexistent the last year and a
half, the other way.
So we're forced to look at other
decisions. The decisions for us is pretty simple.
We'll make this investment, which will exceed $2 million
at the two facilities in the current -- or our best

estimate of the future economic environment, and we make
partial investments and run economically at a reduced
rate at both facilities or close our facilities.
So as we look at that, B and C cause us to
lay off personnel significantly impacting our local
communities. Unemployment nationally is 9 and a half
percent; we're in excess of 12 to 16 percent. We will
get back to the housing starts, economically, we will,
but we'll -- or we're going to regulate ourselves out of
being competitive. That's the question that we -- are
we going to continue to have our production capacity to
our neighbors to the south, South America?

Comment: At the end of the day, we've heard a lot about jobs or costs to industry. Here in Houston, we understand that very well. We hear it every time a regulation is proposed, every time a standard is strengthened, we hear about jobs, but I think there's also a very clear understanding amongst those that actually bear the burden of pollution in this region, that eventually those costs will get passed on to regular citizens.
6And the choice is not between having those costs or not having those costs; it's how those costs will be borne, and I don't think the EPA needs to have another hearing to ask citizens whether they would prefer to bear those costs in increased health expenditures or increase to consumer goods. I think the choice is clear, and I think the EPA is of finally starting to get that, that we need to protect public held to the maximum, that we need to lead industry to innovate, to figure out ways to add control measures that reduce energy use, but also reduce air emissions. And at the end of the day, folks will pay those higher costs for their consumer goods, but they'll be able to do so from a point of view where their -- where their health has been protected, and I think everybody in this region would much prefer to spend a little more on their consumer goods and spend a lot less on their -- on their health expenditures.

Comment: MR. DeLaCRUZ: My name is Ricardo De La Cruz, and I am from Edinburg, Texas. I'm a member of the Pulp and Paper Research Council and I have worked at International Paper for the past 25 years. Here we make corrugated board which is made into corrugated boxes. These are used to package citrus produce to tomatoes televisions, et cetera.

We have two containers and a sheet plant in the county of Hidalgo, Texas. In total, our plants provide 200 green jobs in our county. Many mills around the country with good and safe linerboard supply us. If these mills were to shut down on the impact of the border MACT rules, we would be forced to get our linerboard from China or South America. We have testimonial that the linerboard is tainted with mercury or lead. The American public would not like to have these products packaged in these containers which contain mercury or lead.

Last week, we received a box made in Mexico with linerboard from China and no one wanted to touch it for the fear it was tainted with mercury or lead. Do we want this product coming into the United States? This is the effect of the ruling of MACT and what it would hold.

Comment: The proposed Boiler MACT rule would hit the Coastal community very hard economically. Coastal's cost to comply might approach $40 million of capital costs, which would be a tough pill to swallow for a company that is in a super-competitive, low-margin industry, and whose annual sales is only $200 million. Additional annual operating and maintenance costs could approach $2 million a year. Fortunately, Coastal is one of the best performers in the industry and would probably figure out a way to stay in business. However, I can assure you that many companies in our industry, most of whom have lost millions of dollars over the past three or four years, would choose to simply stop the bleeding and shut down.

Comment: EPA needs to look realistically at the economic impacts of these proposals. And I just add that many of our facilities in the forest products industry are in rural areas where manufacturing family-wage jobs are hard to find. And so we're a major part of a vital and green economy in rural areas. We've been challenged by the recession, which has impacted our industry dramatically. We've lost 350,000 jobs in the industry in total. Some will say we're crying wolf on jobs. I think I can confidently say that these rules, as they're proposed, you're going to find more plant closures.

Comment: The forest products industry is a very significant business in Texas, particularly in the eastern quarter of the state, and in 44 counties of deep East Texas we have three -- the three remaining paper mills are located in deep East Texas. They employ 3,500 workers directly, and the industry is as a whole employs about 54,000 workers across the state, and I think we heard from one of those this morning from a box plant in the valley.
The industry is distributed throughout the state. It is dependant upon the East Texas forest for its raw materials and is a rural industry and an industry that is not concentrated largely in industrial areas of the state. And so I wanted to point out, that as the rules stand, they could have significant impact on rural economies, because it's not -- not a ship-channel issue for the forest projects industry.

Comment: To position the mill for the future, earlier this year we announced plans for a proposed 650,000-pound-per-hour biomass boiler. If the project moves forward it would support our goals to use biomass-based energy, improve efficiencies and solidify the long-term viability of the company. The electricity generated by the boiler would qualify as green power and displace fossil fuels. We are working toward approval of this project by the end of this year.
The proposed Boiler MACT rules would be cost prohibitive for our company. As defined today, the equipment needed to meet the proposed limits would easily kill the project. Additionally, our existing boilers would have to remain in service. These are older units with higher emissions and would incur a very high burden to try to reduce their emissions to

retrofit.
In the state of Washington the cost to
our industry is estimated at $210 million. The proposed
rule would be devastating to the forest industry as a
whole. This is an industry that employs more people
nationwide than automotive or chemical industries.
Across the U.S., Boiler MACT would impose a monetary
burden of 6 to $7 billion on the forest products
industry as well.
Comparatively, the industry has only
profited $1 billion over the last two years. It's not
very hard to see that that sort of imbalance from a cost
to improvement ratio is hard to sustain. It is not logical to us to require a
company with solid environmental performance, in a
industry known to be based on renewable resources, to
comply with the rule as currently written. If the new
rule goes into effect in its current form, the EPA is
putting jobs in our community and business in general at
a great risk. It would impose extremely costly controls
where there is no real environmental or health benefit.

Comment: The Regulatory Impact Analysis does not accurately measure
the impact on smaller plant facilities. By combining
all plant facilities together, the conclusions drawn do
not represent the economic impact to smaller operations.
The cost of capital investment to install control is
disproportionate when comparing a facility that
generates $100 million in annual revenue to a facility
that may only generate $50 million in annual revenue.
The equipment cost is -- the equipment cost does not
correlate to revenue and the ability to absorb the
capital cost is a disproportionate penalty to the
smaller plants. The Impact Analysis contains only data

through 2007 and thus ignores the most devastating impact on shipments, employment, and other operating parameters by not including the worst years of this recession, which have been 2008 and 2009. If one looks at the capacity utilization chart, Figure 2-15 in the RIA, one can visually see that the elimination of 2008 and 2009 data will skew the data and impact any conclusions drawn from it.

The criteria used to classify an "establishment" as large versus small is based on number of employees. This is not a good methodology, in my opinion, since some manufacturing processes are labor intensive and others are highly automated. Production capacity and emissions volume do not necessarily correlate to facility employment.

The collapse of a new housing markets and the recessionary decline in the U.S. economy has severely impacted the wood products industry. I would estimate that 35 to 40 percent of the industry capacity has been curtailed or shut down. These regulations will further reduce the probability of many of these facilities restating when economic conditions improve.

In addition, I would predict that the economic cost of complying with these new regulations will cause new closures as small privately held sawmills and plywood operations and other wood products businesses come to the conclusion that trying to sustain an operation that has had multi-year losses is simply not a good decision. These closures will disproportionately impact rural lower income communities.

In our business, lumber prices have fallen 31 percent since the peak in 2005. It will be difficult to rationalize the cost of installing additional control equipment when that capital does not produce any benefits to the business, and in fact will make U.S. producers less competitive against off-shore suppliers from Brazil, Chile, and China. No other nation in the world has the environmental costs that we have in the United States.

Comment: Our industry is like any other industry struggling to recover. Our forest products industry has been struggling to recover from the recession. Our unemployment rate is still lingering around 10 percent.
The Clean Air Act rule was recently announced -- specifically, Boiler MACT -- could be unsustainable for much of the U.S. manufacturing processes, and also, the very high paying jobs that it provides, unless there can be some greater flexibility allowed in meeting these targets.
The Boiler MACT would require installation of up to four different air pollution control devices, and those would serve -- conflict, in some cases, with

some of our existing controls. The cost to individual plants, such as the one that I work at, would be -- could be as much as tens of millions of dollars in additional capital, which may not be sustainable, given the economic downturn and the fierce international competition. And let me just say that. The fierce international competition.
No other country in the world is imposing requirements like these, which puts -- which makes a very unlevel playing field for us. It puts us at a huge competitive disadvantage. Across the forest products industry, these rules could cost anywhere from $6- to $7 billion over the next two to four years when the industry itself only made a fraction of that over the last two years.
This would result in the severe hardships, and something that I'm very passionate about, could cost tens of thousands of job losses in the forest products sector alone. And given the cost of other likely environmental programs, the compound effects of the -- the compound effects in job losses would be much larger in a sector that's lost 350,000 jobs since the downturn began in 2006. It's much greater than that when you go back to 2001 and 2002.

Comment: Since the '70s, the government has taken a big step to increase air quality, in general, right? In every step that they've taken, the business community has come out and said that we're gonna lose thousands of jobs, it's going to ruin our business, in all of its stuff like that, and really, it hasn't -- like there hasn't been an economic downturn that you can really blame on environmental regulations. The economy is, though, a lot more flexible and able to accept environmental

regulations in general, and in businesses are a lot more flexible than they realize.
I mean, I -- it's just tougher for them to make changes so when -- when looking to make -- to change these rules, just keep that in mind when they come out here and tell you it's gonna ruin our business, we're going to -- thousands of people are going to be unemployed. If you look at the past, that really hasn't happened on a consistent basis.

Response: The EPA analysis for this regulation indicates that production and employment changes are likely to be small. Many of the predictions of large employment changes and closures are based on a lack of market flexibility.

Comment: EPA's proposed rules will create serious disincentives for the use of biomass and alternative fuels and thereby increased use of fossil fuels, which we believe is counterproductive and contrary to the country's energy interests. The rule will have undeniable economic consequences. The forest products industry has projected new equipment required under the proposed rules will cost more than $6 billion over a three-year compliance window plus billions more in subsequent years for operating maintenance expense. Those capital costs alone exceeds industry profit of recent years.

Comment: The Pulp and Paper Resource Council (PPRC) logged over 255 curtailments with mill closures in 2009, on our Web site, pprc.info. On the May 2010 unemployment report just released, the rate of 9.7 percent
unemployment is facing our nation. Our manufacturing facilities do not need this new financial burden placed on them by these new proposed EPA rule changes. There are 23 forest products boilers and 115 more boilers across the great State of Texas. With the proposed changes, the protected cost to change these boilers to meet the new proposed rules are estimated at $1.89 billion just for Texas alone.

Boiler MACT will set emissions limits for hazardous air pollutants from gas, liquid, or solid-fuel fired boilers and process heaters located at universities, in small municipalities, food product processors, furniture makers, federal facilities and a wide range of manufacturers, not just the forest products industry. The EPA's proposed Boiler MACT is so stringent that it will result in significant and unnecessary job losses if finalized in its current form. it would impose extremely costly controls even where there is no significant environmental or health benefits, which is contrary to the direction Congress provided in the Clean Air Act.

5The paper and forest products industry currently employs nearly 900,000 workers. The forest products industry has lost some 350,000 additional -- or 350,000 additional jobs since the beginning of the downturn in 2006, 100,000 jobs lost last year alone. Approximately 75 mills have closed in the last five years. These mill closures were not due to Boiler MACT but the economy and foreign competitors. China is one of the major players and they are not held to the same rigorous environmental standards these American companies are. We need a level playing filed. The entire U.S. paper industry only made $1 billion in the last two years.

This imposed -- this imposed cost will cut more American jobs. The PPRC believes that the forest products industry will be greatly affected. Most of the paper companies across our nation are in rural areas of the states where the backbone of our nation has an agricultural base. We do not need to see these forest products jobs go away. We need to keep America working because we are American workers trying to survive. With these new costs coming so close on the heels of the recent economic downturn, the would be unavoidable and severe financial distress and economic disruption for the workers, families, and communities for whom paper and wood products companies are the primary, or the only economic engine. My mill boasts a payroll of $70 million and more than $4 million is paid annually in property taxes, which mainly benefit the local school districts. There are sales taxes in excess of $909,000 and approximately $350 million spent in vendor supplier-wood relationships.

Comment: The forest and paper products industry were green even before there was a label for being green. We have had green jobs for over a century, but only until recent years has there been a "buzzword" for being environmentally responsible. The forest products industry will always be the best environmental stewards of our forest and land. We are sustainable, renewable, and the greenest. We do not want our jobs, livelihood, and communities destroyed by your legislated rules that bring about unintended consequences of jobs lost. Your unintended consequences of stringent rules will put more mills on our map out of business. There are American workers' names that go with the numbers on our map [see map provided as supplemental information to transcript]. The hourly workers are almost always the first to go. The PPRC urges you to "Seek a Balance"
between the environment and industry.

Comment: The rule will substantially increase compliance costs. The proposed changes come at a time when mill closures/curtailments have reduced OSB board production by nearly 50 percent. Regulations that do little to improve the environment eventually threaten jobs and can lead to permanent rather than temporary closures.
And I close on a personal note. Norbord has two OSB mills in Texas; one located in Nacogdoches, the other at Jefferson. Within the past three years, Norbord has invested over $10 million at each location on PCWP MACT improvements. Unfortunately, the Jefferson mill was closed indefinitely January 2009 due to economic conditions (our products are used directly in the housing industry). One hundred employees lost their jobs. The decision to re-opening this mill will be measured against several factors, not the least of which would be additional capital investment to meet more stringent environment standards.

Comment: We are in the process of reviewing and conducting detail site-specific engineering review to determine the Boiler MACT compliance costs for NewPage. However, preliminary cost estimates for NewPage indicate capital expenditure of greater than $100 million, and potentially several million dollars in additional annual operating costs for these facilities. These costs are

significant and will put NewPage at a distinct
disadvantage as we compete in a global marketplace with
other paper producers located in jurisdictions that do
not have to comply with these requirements. EPA needs
to be including flexibility options that allow for
alternate compliance approaches.

Comment: The proposed rules (referred to herein as the "Boiler MACT" or the "Rules") set stringent emission limits for hazardous air pollutants from industrial, commercial, and institutional boilers that combust fossil fuels and biomass. Because of the broad sweep of the Rules and ultra-low emissions levels they impose, even for boilers using relatively clean fuels like natural gas and processed fats, we are concerned about the negative impacts of them – both economically and technologically. In terms of the economic burden, the capital cost expenditures are estimated to be in the tens of billions of dollars at thousands of facilities across the country. This is more burden than industry can bear in these economically challenging times. A wide range of sectors and the jobs they sustain would be severely harmed – universities, small municipalities, food product processors, furniture makers, federal facilities, and a wide range of manufacturers and other businesses that operate gas, liquid, or solid-fueled fired boilers.

Comment: I am greatly concerned over EPA's proposed Boiler MACT rule and the implications therein that would significantly burden, and have the potential to limit or close operations at our existing boiler and cogeneration facility. The continued effect to provide steam or electricity to our industry via non-wood/biomass only add cost burden and dependence on fossil and foreign fuels -both of which further limit the viability of the wood-products industry.

Comment: Troy Lumber Company's facility includes a saw mill, a planer mill, two (2) boilers, and two (2) lumber drying kilns. Our facility processes Southern Yellow Pine logs into finished lumber. Our industry has been in a 10 year squeeze on our profit margins. We pay more for the logs than in the past yet get less for the lumber than any time in our long history. We have over 100 employees and offer them a competitive salary and full benefits. This proposed regulation will have a devastating effect on our facility as well as our suppliers and our customers. Many wood-related businesses in North Carolina will simple cease to exist if they have to upgrade their air pollution control devices from cyclones to bag houses or electrostatic precipitators and to install continuous opacity monitors. In our small, poor, rural, economically depressed county this measure could effectively double our unemployment rate. This is due to the cost to purchase, install and operate the new equipment which has not been proven to accomplish the goals the new rules prescribe.

Comment: Across the forest products industry, these rules could cost $6 to 7 billion over the next two to four years. This will result in severe hardship and thousands of job losses in the forest products sector. The costs to individual mills could be tens of millions in additional capital expenditures.

I am writing representing Steely Lumber Co., Inc., a family-owned southern pine sawmill company that has been in business since 1896 and currently employs close to 90 people. We currently operate two wood byproduct fired boilers that just barely go over the threshold for this new rule. We operate and comply to TCEQ regulations, but this new MACT rule would likely cost us near $2 million dollars to comply with. This is a hit that we could not recover from. This would force us to consider new alternatives to dry lumber and would likely put us out of business. I strongly suggest the EPA reevaluate the proposed rule.

Comment: We believe EPA has significant discretion in the MACT program to protect public health while avoiding the unnecessary burdens these proposed regulations could impose. Boiler MACT could cost the forest products industry alone over $6 billion in capital expenditures and hundreds of millions more in annual costs unless significant changes are made.

We are coming out of the worst economic recession since the Great Depression, and the forest products industry has lost over 350,000 jobs in the last three years. To be a sustainable industry supporting high-paying jobs and providing sustainable products, we need sustainable environmental regulations.

Otherwise, costs of this scale will force further mill closures and tens and even hundreds of thousands s of additional job losses, especially given other expected, significant environmental regulatory costs.

Exports will drop, and imports will increase since no other county is contemplating requirements this extreme.

Comment: CECONY also operates some steam system boilers on residual oil in areas of New York City where the natural gas infrastructure is insufficient to provide natural gas in quantities capable of firing these boilers. Although it is the largest district steam system in the United States, the CECONY system only serves approximately 1,800 municipal, institutional, commercial, and residential customer accounts. The cost of wide-scale gas system improvements of a magnitude sufficient to fire these steam system boilers would be prohibitive over this limited customer base.

Comment: The NAM is the leading voice for the manufacturing economy in Washington, D.C., which provides millions of high-wage jobs in the U.S. and generates more than $1.6 trillion in GDP. In addition, 80 percent of NAM members are small businesses which serve as the engine for job growth.
The EPA's proposal to impose more emission standards on industrial boilers will cut across all sectors of the NAM membership, including the chemical, auto, metalworking, petroleum refining, and forest and paper sectors. New standards for industrial boilers will have an immediate impact on our members' bottom line.

Manufacturers are attempting to fully recover from the steepest economic downturn since the 1930's and bring back the 2.2 million high-wage jobs lost during the previous recession. Federal policymakers should create conditions that will lead to economic expansion and not stifle the vitality necessary to create jobs and technologies that will continue to improve the nation's air quality. Imposing stricter mandates on the manufacturing sector will not accomplish any of these objectives.

Comment: I joined the Pulp and Paperworkers Resource Council over 10 years ago when I saw American jobs leaving at an alarming rate. We’re hourly workers from competing companies, working together as brothers to save our jobs. The economy, higher fiber and energy costs added to the need for a profit, combined with increasing regulatory costs, can be the nail in the coffin. Creating new jobs is a must, but don't get rid of the remaining jobs we have left.

Our company is a leader in sustainability and has been for generations. We support efforts to protect the environment and have voluntarily worked to reduce emissions in our manufacturing operations. Together with other leaders in our industry, paper and forest products manufacturers have reduced air pollution from our operations by more than 50 percent in the past 20 years.

As you know, the industry is one of the most heavily regulated in the United States. It harms our ability to compete with manufacturers in countries that do not share our commitment to environmental performance. Despite this burden, new regulations, such as the Boiler MACT, continue to be proposed that would require additional investment with no substantial environmental benefit.

Comment: It is our concern that if Boiler MACT continues in its present form, the American forest products industry and the communities it supports will ultimately meet the same fate.

Our nation’s recent economic down turn has not been very kind to the forest products industry. In the past two years, our industry’s profits were approximately $1 billion. Over 40 mills closed, and another 150 had to take idled down time. Tens of thousands of high-paying jobs have been lost, and the way of life as we knew it has drastically changed. The capacity of these mills has been shifted to emerging overseas’ markets such as China and Brazil, where companies can operate with little or no environmental or labor regulations.

If these current standards are implemented, the cost to an already struggling industry will be devastating. As I have previously stated, our industry’s profits were approximately $1 billion. And that is for our whole industry, not just Smurfit-Stone Container -– the whole industry was $1 billion. For the past two years that’s about what we made.

To meet these new standards and be EPA compliant, our industry will have to spend approximately 6 to $7 billion, and this could be the final blow to the American forest products industry, forcing our companies to close their doors, move their operations overseas. When this happens, we will not only have lost a high-paying, tax-generating jobs that help support our country, we will also be multiplying the very same emissions that we are trying to control in the first place, causing the American people to lose all the way around.

Comment: In 2009 our Number 3 paper machine was shut down due to economic downturn. As a result of this shutdown, some 110 people were out of work for about a year. But it’s not just the mills that are affected; there is a ripple effect on the jobs in the community as well. There are 4 to 10 jobs related to every one job at the mill. As a result, many other families were affected during the machine’s downtime as well. Thankfully, this machine is back up and running in 2010, and most of the workers are back on the job. These jobs are so important to rural areas where median wages so very low even with mill workers’ salaries figured in.

I’ve painted you the picture of where I work and what we face, but there is a much larger picture. The paper and forest industry employs nearly 900,000 workers. The forest products industry has lost more than 350,000 jobs since the beginning of the downturn in 2006 –- a hundred thousand of these jobs last year alone. Approximately 75 mills have been closed in the last five years.

These mill closures were not due to Boiler MACT but the economy and foreign competition. China and Latin America are the major players and are not held to the same rigorous environmental standards as American companies face. We need a level playing field. The entire paper industry made only one billion dollars in the last two years, as you previously heard. The cost of Boiler MACT in the State of Georgia alone is going to be somewhere around $520 million, and across the industry in the next two to four years could be 6 to $7 billion.

The proposed Boiler MACT rule could damage the manufacturing sector's ability to recover during these hard economic times and is far more restrictive than needed to protect the environment.

Comment: The standards for new boilers are so stringent that boiler manufacturers cannot guaranty compliance, which will assuredly stifle investment in new systems that feed economic growth.

The total capital costs for the forest products industry alone are estimated around 7 billion for the next two to four years, which I heard mentioned earlier. And the cost for all manufacturing could be 20 to 50 billion. Those are huge numbers.

In Michigan and West Virginia, the states where SFK has operations, the boiler MACT costs for the forest products industry are expected to be approximately 270 million and 20 million, respectively. Those numbers are staggering by themselves, but take into account that the entire forest products industry only made one billion dollars in each of the last two years.

This will result in severe hardship and tens of thousands of job losses in the forest products sector alone. Given the cost of other likely environmental programs, the compounded effects will result in hundreds of thousands of job losses in a sector that lost 350,000 jobs since 2006.

Comment: In my position I often hear the comment, are they trying to regulate business out of this country. And our business has been cut in half over the last couple years as we are tied directly to the housing market. And we're also under increased pressure from the regulatory side from both OSHA and the EPA. And these new regulations do come at a price, despite what many of the speakers, I believe, felt here today. Industry does not have unlimited resources and funding.

Regulations such as this put a heavy burden on industry and will drive many manufacturers out of business and to other counties.

I urge you to, strike a balance with these regulations and work towards a cleaner environment but help us stay in business and stay in the country.

Comment Excerpt Number: 1

Comment: The proposed Boiler MACT rules, if adopted, present a potential financial impact that very likely could result in the closing of business and loss of jobs to nearly 100 people living in an area with an average unemployment rate of 13%. The closure of Keadle Lumber Enterprises would have a far reaching impact in the loss of revenue to area businesses, loss of tax revenue to federal, state and local governments, and the negative impact of one more empty manufacturing facility in a once thriving community. The potential costs of controls proposed while being exorbitant, will not necessarily meet limits and will most likely result in the abandonment of Biomass fueled boilers in favor of cheaper natural gas boilers. These natural gas boilers will increase costs to the facility making an already depressed industry even less competitive in the market place.

Comment: Millions of dollars worth of pollution equipment to every boiler would be the final blow to an already battered industry. Many, many, sawmills have been shut down for sometime, due to the awful housing market. I can give you a perfect example of one. There is another mill in our small rural town. It has been shut down for almost 3 years, now, and its 100 employees laid off. That company has diligently kept two employees working keeping their equipment greased, tested, and maintained for an expected start up at the first opportunity. That company had hopes of starting back up near the end of the year. I know they, now, can't even consider it with the Boiler MACT proposal facing them. How can they start up a mill when they can barely afford to do so under the best of circumstances, much less, when they will have to put out millions before they put the first employee back to work?

Here is another personal example from our operation: We have barely survived through the recession and for most of last year ran only 30 hours per week. We were able to survive primarily because we are an export mill cutting lumber for world markets and were not as damaged by the housing bust. (We are one of the good guys, helping the trade deficit.)

Comment Excerpt Number: 13

Comment: The rationale that supports the proposed approach for the Gas 1 subcategory applies equally well to biomass boilers and, therefore, provides ample support for adopting work practices instead of numeric emissions limitation for biomass boilers. For example, in the forest products industry alone, the estimated cost of complying with the proposed HAP emissions limitations for biomass boilers is $3.3 billion. This is an extraordinary cost that, in the context of the forest products industry, equals or exceeds the magnitude of the economic burden that EPA predicts for the Gas 1 subcategory. Similarly severe economic impacts are expected in other industry sectors where biomass boilers are widely use, such as the furniture, sugar, and agricultural products industries. Thus, there is strong economic justification for prescribing work practice standards for biomass boilers in lieu of numeric emissions limitations.

Comment Excerpt Number: 1

Comment: KapStone's main concern with the proposed Industrial Boiler MACT is the proposed standards are far more stringent than needed to assure protection of health and the environment from industrial boiler HAP emissions and do not strike a balance with economic health of the effected sources. As described in detail below, KapStone is committed to operating in an environmentally responsible and sustainable manner. The pulp and paper industry faces a withering global economic slump and fierce competition from overseas manufacturers. Therefore, it is imperative for mandatory environmental controls such as the Industrial Boiler MACT standard to be tailored as closely as possible such that health and the environment are protected without requiring unnecessary expenditures of time and resources.

Comment: As our company, together with the entire wood products industry, struggles to recover from the worst downturn in decades, the potential impact of the Boiler MACT rule may drive companies as ours out of business.
It is our belief that to comply with the proposed rule, we need to spend an estimated $8,000,000 to $10,000,000 in direct capital expenditures. This is more than we have spent on capital improvements over the last 5 years combined! Moreover, compliance would require estimated additional operating expenses close to $2,000,000 per year. We do not believe that the housing market (the main market for our products) can support such a cost increase, so the possibility of us closing down is very real. Tolleson Lumber Company has been in existence since 1919 and currently employs 280 people. At full capacity we employ 380.

Commenter Name: J.R. Randy Bush
Commenter Affiliation: Virginia Forest Products Association
Document Control Number: EPA-HQ-OAR-2002-0058-2402.1
Comment Excerpt Number: 1

Comment: Virginia's forest products industry is one of the State's largest manufacturing activities. A recent government sponsored economic study1 shows that forestry and agriculture comprise the largest economic segment of the Commonwealth, with forestry contributing $23 billion annually in total economic impact while providing jobs for 144,000 Virginians. Forests are the largest land use in the State, covering 62% of Virginia's land mass, and forest products related economic activity is found in every county and city of the Commonwealth.
Of the boilers initially identified in Virginia that would be impacted by this regulation, nearly half are attributable to paper, solid wood, or furniture manufacturing. It is estimated that through this regulation just the paper and solid wood boilers alone will have a capital cost of $230,000,000 ... with all impacted boilers in Virginia facing a potential capital cost of $930,000,000. And this is just for Virginia, nationwide the potential cost is over $18 billion! Recent economic conditions have placed a severe toll on the industry ... easily the worst since the Depression, with many facilities closing their doors either temporarily or permanently. As an example, studies have shown the number of sawmills in the State in 2009 is one-half of the total found in 1999, just 10 years previous. Any additional regulatory burdens placed on the industry, particularly those that have questionable cost vs. benefit ratios, will put many more facilities at risk.

A single unifying theme lies at the heart of our comments on the proposed Industrial Boiler MACT standard – the proposed standards are far more stringent than needed to assure protection of health and the environment from industrial boiler HAP emissions. As stated earlier, the membership of the Virginia Forest Products Association faces a withering global economic slump and fierce competition from overseas manufacturers. Therefore, it is imperative for mandatory environmental controls such as the Industrial Boiler MACT standard to be tailored as closely as possible such that health and the environment are protected without requiring unnecessary expenditures of time and resources.

Document Control Number: EPA-HQ-OAR-2002-0058-2387.1

Comment Excerpt Number: 1

Comment: Boralex owns six biomass electrical generating facilities in the US. Five are located in Maine and one in upper state New York. All are located in rural areas that provide a source of job opportunity to local residents and service related businesses. Each facility provides a significant tax base to the communities they reside in. Boralex provides over $75M annually to purchase processed biomass fuel, perform facility maintenance, pay employee salaries and to pay federal, state & local taxes, mostly in Maine and New York State. [See submission for list of Boralex facilities] Since 2004, Boralex has invested over $54 M into its biomass generating facilities to improve efficiencies, upgrade emission control devices and to maintain plant operating integrity. [See submission for capital investments to-date.]
Boralex continues to make substantial investment into the operations of its five operating biomass power plants. These plants provide good-paying jobs and benefits directly to over 150 people working at these facilities. Fuel procurement (fuel processing and transportation) provides an additional 400 jobs. Boralex contributes significantly to both local and state economies through taxes paid, fuels, equipment and consumables purchased and employment of area contractors during scheduled maintenance shutdowns. Operation of these facilities is being accomplished at a time when competition for energy sales is very aggressive, prices for renewable generation are low and the cost of operating biomass-fired power plants is substantial. The current limits imposed in the proposed MACT rule are going to present a significant and very costly challenge to Boralex. If the rule is implemented as written, Boralex could very well be faced with a decision to defer plant operations at their biomass electrical generating facilities, permanently close these facilities, or possibly relocate them out of the US.
As this tragedy unfolds, the economic well being and future of at least 500 people, either working directly to operate the Boralex biomass facilities or indirectly as fuel suppliers or other support services, along with countless others in Maine's biomass energy sector and over 18,000 people working in the biomass energy industry across the US will be placed in jeopardy. All those depending upon the success of this industry will be placed in the throes of a situation imposing unrealistic, unattainable and very costly demands, with insignificant environmental, health or societal benefit, while placing the collective futures of our employees and this industry in grave peril of extinction.

Document Control Number: EPA-HQ-OAR-2002-0058-2719.1
Comment Excerpt Number: 1

Comment: The memberships of the AEF and AFPC are concerned about the proposed Boiler MACT rule —the Maximum Achievable Control Technology rule for industrial, commercial and institutional boilers and process heaters — that was published June 4, 2010. Arkansas is in the midst of severe economic distress, as is the rest of the nation. Since June 1995, Arkansas has lost nearly 100,000 manufacturing jobs, roughly 40 percent of that sector's employment. The proposed Boiler MACT will stymie economic recovery for many industrial sectors, particularly for the forest products sector.

That sector employs over 29,000 workers, primarily in the south Arkansas area. In fact, the forest products sector is the single largest driver of the economy in south Arkansas, and has itself suffered serious decline in recent years due to foreign competition, market pricing and lack of product demand as the housing market has tanked. The added burden of compliance with the Boiler MACT proposed rule will, without a doubt, cost Arkansas jobs and investments. As one mill owner noted recently, environmental compliance costs in the forest products sector cannot be passed through nor is there a return on the investment. It is a direct cost that will replace planned efficiency upgrades and expansions.
The impact of the MACT is not limited to large wood products companies however. Costly regulatory burdens under Boiler MACT will be felt by municipalities, universities, government facilities, and commercial entities. It has been estimated that costs to these entities in Arkansas alone will total $490 million, with roughly $390 million borne by the wood products sector.

We understand that the Boiler MACT rule alone could impose tens of billions of dollars in capital costs at thousands of facilities across the country. As EPA develops a final Boiler MACT rule, the AEF and AFPC strongly encourages the Agency to consider the impact of the MACT on the economy of our struggling state, investments and jobs.

Comment: The US home construction industry is at near depression levels of business. Businesses that support the construction of housing in the US are dramatically impacted by the events that have unfolded since ~2007. Regulations requiring expensive control devices will further drive business off-shore to business friendly countries. Our facility, while a Title V Major source of VOC's from finishing operations, has a small wood fired boiler (19MMBtu/h) used to provide comfort and process heat. This water tube boiler was exempted under the 2004 Boiler MACT. Under Section E of the Preamble, EPA admits "We could not identify better HAP emissions reduction approaches that could achieve greater emissions reductions of HAP than the control technology combination (fabric filter, carbon injection, scrubber, and GCP) that we expect will be used to meet the MACT floor level of control". The regulation, as written, will probably result in many in the industry making a decision to shut down or move off-shore.

Comment: Under the proposed rules, facilities could spend millions of dollars on controls and still not meet emission standards. The additional costs will be passed on to consumers and the producer is no longer competitive. Production and jobs for many facilities could be relocated to foreign countries where little concern for the environment exists and will cause a greater detriment to the environment and our economy than burning legitimate fuels in properly functioning boilers.

Response: First part is cost question: will what is costed meet the standard
The EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs. The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). The analysis shows market responses with a very small increase in imports and a small job change.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 2

Comment: The boilers operated at Forest Products facilities are already regulated by a variety of environmental programs, and face even further regulation by additional programs being considered by EPA. The additional regulatory programs being considered by EPA will significantly increase capital and operational costs for the Forest Products Industry and jeopardize the long term viability of a healthy forest products industry (see Cumulative Burden White Paper – Appendix B).
AF&PA has studied the possible cumulative cost burden on forest products industry mills from the following regulatory actions, as illustrated in Appendix C:
* Boiler MACT revisions (for major HAP sources);
* Boiler GACT (for area HAP sources);
* CISWI revisions/new non-hazardous solid waste definition;
* Reopening other MACT standards for the pulp and paper and wood products sectors
* Regulation of hydrogen sulfide under section 112:
* Potential future inclusion of industrial boilers in CAIR;
* Lowering of NOx, SO2, and ozone NAAQS;
* Lowering and full implementation of the PM2.5 NAAQS; and
* Additional retrofit controls to enable states to meet reasonable further progress milestones under the Regional Haze Rule.

The cost burden for our facilities with industrial boilers, if all of these regulatory actions occur, could be $16.5 billion in capital over the next three to eight years and $1.7 billion in annual operating costs, for a total annualized cost of $3.7 billion. This represents four times the annual profits for the forest product industry the last two years. The anticipated control retrofits under the revised Boiler MACT are expected to comprise almost half of the cost impact. This analysis did not include the potential impact of the recently finalized PSD Tailoring rule which ignores the long standing principle of carbon neutrality and, like Boiler MACT, will discourage the use of biomass whether at existing boilers or new biomass boilers and potentially reverse the trend in the forest product industry's increasing energy production from biomass. A report entitled "Cumulative Cost Burden Analysis of Air Regulations Potentially Impacting the Forest Products Industry", which outlines the details of this tremendous burden of Clean Air regulations, is included in Appendix D.

Document Control Number: EPA-HQ-OAR-2002-0058-2601
Comment Excerpt Number: 3

Comment: Because of the costly control devices that would have to be installed, the pending Boiler MACT policy could restrict resources for potential investment and hiring, therefore, jeopardizing the future of the manufacturing industry and its important role in the state's economy.

The repercussions of the Boiler MACT rule would touch other key groups in the state as well. From businesses, local governments, and government research entities to universities and commercial facilities, the cost under Boiler MACT in Mississippi, alone, has been estimated at $360 million.

This rule would have far-reaching effects, costing billions of dollars for manufacturers and other groups in states throughout the country. Although I am certainly a proponent of reducing the health risks associated with toxic air emissions, I believe we must do so in a way that upholds the sustainability of the market. I urge you to consider alternative approaches that protect the health of our people and accommodate the critical need for jobs.

Response: The EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with
expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs. The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). This analysis was done on the national level for many reasons. Impacts on price level, international trade, national production, and jobs could not have been estimated if the analysis focussed on regional or state levels. EPA also does not have the necessary data to estimate impacts on individual

states. Even if EPA had the data a detailed estimate of individual state and industry responses would be beyond the scope of what could be accomplished for this analysis.

Comment Excerpt Number: 4

Comment: The proposed MACT standards for Major Source boilers as well as Area Source boilers would be highly detrimental to our business too. The cost to comply with these new, stringent standards would jeopardize our ability to continue in business. That in turn would negatively affect our employees, our contractors, our suppliers, and the local and regional community. AF&PA has estimated that these new rules would cost the wood products industry $6 to $7 billion dollars over the next four years. In our own State of Montana, they estimate that there are seven Forest Products in operation, and that it would cost $60,000,000 in capital costs to bring those boilers into compliance with the new MACT standards. That works out to an incredible $8,500,000 per boiler. Don Wolf, of Burns & McDonnell Engineering Co. of St. Louis confirms this when he says "…the average capital cost of retrofitting biomass-fired boilers will be nearly $5 million". Furthermore, he estimates that "…air-pollution-control retrofit projects/fuel-switching projects can take 18 months to three years from the start of compliance planning through engineering and construction to startup." Our company has struggled mightily over the last several years to survive the severe economic downturn. Our business simply could not bear an added expense of that magnitude.

Response: The EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs. The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). This analysis was done as a national analysis for many reasons. Impacts on price level, international trade, national production, and jobs could not have been estimated if the analysis focussed on individual entities. EPA also does not have the necessary data to estimate impacts on individual entities because much of it is proprietary. Even if EPA had the data a detailed estimate of individual entity responses for so many entities in so many sectors would be beyond the scope of what could be accomplished for this analysis.

Comment: AF&PA engaged Fisher International Inc. to assess the impact of the estimated compliance costs related to Boiler MACT and other upcoming air regulations on the economic viability of U.S. pulp and paper mills (see report in Appendix G). To estimate the impact of new air pollution control regulations on the U.S. pulp and paper industry, they used Fisher Solve, a proprietary industry database describing the assets and costs-of-production of each mill, and the estimated costs of controls that would likely be required for each mill to comply with the proposed Boiler MACT. Fisher projected the costs of compliance for each mill and calculated them as a percentage of the mill's costs of production. When compliance would increase a mill's cost-of-production by more than a sustainable amount, they listed that mill and its associated employment as being "at-risk." The results show that the Boiler MACT regulations alone, if they are incremental to the other pending manufacturing-related air regulations, would result in the closure of 30 mills employing 16,888 people or 14% of total employment at pulp and paper mills.

The pulp and paper mill jobs that would be at-risk due to air regulation changes support jobs in other industries that supply the pulp and paper industry and in local communities and throughout the U.S. due to the re-spending of worker incomes. A scholarly paper prepared by the Economic Policy Institute -- "Updated Employment Multipliers for the US Economy, 2003" -- was provided to Fisher by AF&PA. Table 9 of that paper indicates that for every 100 jobs in the paper industry, there are an additional 325 jobs sustained in other industries due to the purchase of supplies and the re-spending of worker incomes. Hence, the multiplier works about to 4.25. Applying the 4.25 multiplier to the job losses projected suggests that 72,000 jobs can be lost by imposing the proposed boiler MACT regulations (16,888 X 4.25 = 71,774).

Boiler MACT (and other potential upcoming Clean Air regulations) will adversely impact the sustainability of the forest products industry. Given foreign competition and the capacity of production, prices for various forest products (pulp, paper and wood products) are determined by world markets. In fact, the US share of paper capacity is declining and expected to continue to decline relative to emerging paper producing countries such as China [see submittal for chart showing global paper capacity]. Therefore, increases in production cost due to complying with overly stringent Boiler MACT limits (that exist due to inappropriate data, calculation, and technology assumptions) will not be able to be passed along to customers but instead borne by the mill or company. In the last two years, forest product industry profits have averaged just one billion dollars so absorbing twice that amount for a single new regulation ($1.7 billion) reinforces the conclusions of the Fisher International Inc. costs for Boiler MACT compliance and resulting job loss analysis.

The forest product industry and especially the pulp and paper sector is very capital intensive. Over the last fifteen years, the industry has failed to return its cost of capital (see submittal for chart showing costs of capital and returns over time) which in part has lead to many mill closures (over 150 in the last decade) and could prevent the ongoing viability of many more. This negative financial situation adds to the urgency of carefully assessing the magnitude of any new capital obligations through environmental regulations. Where there is discretion, and we believe the Clean Air Act provides as much as outlined below, EPA should embrace more reasonable emissions limits that reflect the variability of best performer boilers and avoid controls for threshold pollutants where risks are shown to be acceptable.

Comment: A single unifying theme lies at the heart of our comments on the proposed Industrial Boiler MACT standard – the proposed standards are far more stringent than needed to assure protection of health and the environment from industrial boiler HAP emissions. We are committed to operating in an environmentally responsible and sustainable manner. However, as an industry we are facing a withering economic slump and fierce competition from overseas. Therefore, it is imperative for mandatory environmental controls such as the Industrial Boiler MACT standard to be tailored as closely as possible such that health and the environment are protected without requiring unnecessary expenditures of time and resources. EPA has the legal discretion and technical justification to substantially reduce the burden of the standard while still providing ample protection to health and the environment.
EPA can provide reasonable approaches in its final Boiler MACT rule that will improve air quality and target investments strategically, preventing severe job losses and tens of billions of dollars in unnecessary regulatory costs.

Comment: We are extremely concerned that the proposed industrial Boiler MACT standards will impede manufacturing recovery in this country and create even more severe competitive disadvantages for our companies in the global marketplace. I call to your attention the following points:

At a time when our economy is fragile and our country faces almost 10% unemployment, this proposed standard would add a significant layer of costs for industry that will close factories, mills, and businesses, and cost thousands of additional jobs.

In the forest products industry alone, these rules could cost $6-7 billion over the next two to four years when the industry only earned one billion in each of the last two years. This will result in severe hardship and tens of thousands of job losses in this sector.

This regulation will no doubt encourage US manufacturing to move off-shore and will increase reliance on imported fossil fuels.

Comment: At its Newport News shipyard, NGSB owns and operates five residual oil-fired industrial boilers (consisting of three -powerhouse" stationary boilers for supplying process and building steam, and two barge-mounted boilers for supplying high pressure steam to ships under construction). NGSB also operates various natural gas or distillate oil-fired boilers to produce steam or hot water process heating and comfort heating in buildings and warehouses located at the Newport News shipyard and throughout the Gulf Coast operations. NGSB has determined that these boilers will be significantly, adversely affected by these regulations, if adopted as proposed.

Comment: Jobs directly associated with the sugar industry include those employed at the sugar mills, those employed in the agricultural operations, and administrative personnel. In Florida, the total direct employment in the sugar industry is approximately 5,000 persons; in Texas, it is 1,000 persons; and in Hawaii, it is 800 persons. Indirect employment (contractors, vendors, consultants, etc.) is many times these numbers.

The worst case impact of the proposed Boiler MACT rule is the complete shutdown of the sugar industry in the U.S and the moving of it overseas. In this case, the total U.S. employment loss would be approximately 6,800 persons. A less conservative estimate would be the closing of several mills and further consolidation of the industry. Consolidation would likely cut approximately 2,000 employees in Florida and 500 in Texas from the payrolls. Due to the locations of all the mills in or very nearby small agricultural-based towns, that depend 75% to 100% on these sugar mills for their local economy, these towns, such as the "Glades" areas of South Florida, will fall into financial ruin by the closing of these mills.

Comment: If properly designed to reflect the broad range of boiler designs and operational conditions, as well as manufacturers' emission guarantee levels, the Boiler MACT will stimulate the creation of jobs in the boiler and boiler-related equipment industry. To the extent that EPA develops a Boiler MACT rulemaking that is achievable in practice for boiler owners and operators, the proposal will create solid, well-paid, professional, skilled and unskilled manufacturing jobs attendant to the upgrade, optimization and replacement of existing boilers around the United States. In addition, service jobs associated with the installation and maintenance of these systems, as well as service jobs associated with required tune-ups and energy assessments will be created. These jobs will be significant contributions to our local, state and national economies – contributions that must not be overlooked or minimized.

Response: EPA attempted to estimate the increase in jobs due to the proposed regulation. All catagories were not captured quantitatively.

Comment: In order to support biomass facilities and other renewable energy resources, California imposes a public goods charge to provide incentives and financial support to make them economically viable. More than 70 percent of California's biopower generation from solid-fuel biomass facilities in the State receives funding from this program.

Despite State subsidies, the total generating capacity from solid fuel biomass has decreased from 994 megawatts (MW) in the 1990s to 667 MW today, despite a potential to generate 3,421 MW from biomass resources. Only one new facility has been developed since 2000.

The power plants also have existing power purchase agreements and would not be able to pass the cost of the retrofit on to utility ratepayers. The Energy Commission's analysis indicates that the existing biomass power plants would not be able to fund the retrofit needed to meet the MACT Rule and would discontinue operation.

Comment: I urge your reconsideration of the Boiler MACT rule. We are in perilous economic times and further regulation on our industries will simply be catastrophic. Industries in America are the most regulated in the world and are finding it increasingly difficult to compete in a global market. The proposed rule is unnecessarily stringent and costly.

Response: The EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs.

The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). The analysis did not show large changes in production, prices, or imports.

Comment: As proposed, capital investments of up to $50 million dollars would be necessary in order for the Puunene Mill boilers to comply with the Boiler MACT standards, assuming compliance with the standards is possible at all for the existing boilers. In addition, annual facility operating costs would be expected to increase by up to $6 million. These are costs which HC&S may simply be unable to bear, threatening the continued viability of the company, along with its 800 well-paying jobs and $100 million annual contribution to the local economy, at a time when Maui, like the rest of the nation, is already struggling to cope with a prolonged economic downturn and the job losses that have come with it.

Document Control Number: EPA-HQ-OAR-2002-0058-2718.1
Comment Excerpt Number: 1

Comment: It is vital to consider that manufacturers, including the food industry, are attempting to fully recover from the steepest economic downturn since the 1930s and bring back the 2.2 million high-wage jobs, including those in the food retail and food service industries, lost during recent years. FIEC strongly urges federal policy makers to create conditions that will lead to economic expansion and not stifle the industrial and manufacturing vitality necessary to create jobs and technologies that will continue to improve the nation's air quality. Imposing unduly strict mandates on food processors will not accomplish any of these objectives.

New and overly stringent standards for industrial boilers will have an immediate impact on many food producers bottom line without demonstrated environmental benefits. Compliance costs associated with these harsh and inflexible proposed rules will cost U.S. manufacturing jobs and hurt global competitiveness, just as the economic recovery attempts to gain more traction. Further, as described below, the severity of the proposed standards may lead to the revaluation of projects that otherwise would realize environmental improvements.

Comment: OFIC appreciates that the Environmental Protection Agency (EPA) has limited ability to take the current economic situation into consideration when promulgating the MACT and associated rules. However, Oregon is suffering from unemployment numbers far above the national average, and in some cases in rural Oregon TWICE the national average. OFIC urges EPA to consider the context of the rulemaking not as a factor inand-of-itself but rather as motivation to try to find every legal and administrative way to avoid the certain, draconian impacts on the forest sector that will occur if the proposed rule is implemented as written.

Comment: Our Company is working aggressively to emerge from creditor protection. At the same time, this regulation represents an additional capital cost for each individual facility – tens of millions of dollars in most cases. Based on a preliminary assessment, the Company estimates it will cost close to $200 million for all six of its US paper mills to meet new compliance standards, and we are not sure it can be done consistently with current technology. This dilemma puts several of our facilities and our jobs at risk. We are aware that in the U.S., this rule will cost the forest products industry almost $7 billion over the next two to four years – an amount that is not sustainable in today's economy.
Over the past ten years, our Company has permanently closed six pulp, paper and wood products facilities in the U.S. and indefinitely idled one due to high operating costs that prohibited them from successfully competing in the marketplace, and put thousands of our fellow employees out of a job.
The proposed rule is unnecessarily stringent and costly.

Document Control Number: EPA-HQ-OAR-2002-0058-3153.1
Comment Excerpt Number: 1

Comment: We believe the proposed Industrial Boiler MACT standards are far more stringent than needed to assure protection of health and the environment from industrial boiler emissions of hazardous air pollutants (I-IAPs). As AbitibiBowater emerges from Chapter 11 bankruptcy protection in the second half of 2010, we face a withering global economic slump and fierce competition from overseas manufacturers. Over the past ten years, AbitibiBowater has indefinitely idled one and closed six facilities in the U.S. due to high operating costs. In 2008, Augusta Newsprint was forced to take eleven days curtailment of operations due to the lack of newsprint orders. In 2009, thirty-nine days of curtailment were imposed on the Augusta mill, reflecting the continuing decline in the newsprint market. Therefore, it is imperative that the Industrial Boiler MACT standard be tailored to protect health and the environment without requiring unnecessary expenditures of time and resources.

Estimates show that $12-14 million in initial capital would be required for Augusta Newsprint Company to begin to make the necessary alterations to meet these stringent proposed limits, not including additional annual operating and labor costs associated with maintaining regulatory equipment, compliance tests, etc. With no return on investment and no economic gain, and at a time when we are already struggling to maintain profitability and to be a viable competitor in a declining newsprint market, the sustainability of Augusta Newsprint would be in jeopardy.

Comment: In 2010 Boulder County received grant funding from the US Forest Service, The Department of Energy and the Colorado Department of Local Affairs as well as Qualified Energy Conservation Bonds to install another 3.3MMBtu biomass boiler at the 150,296 square foot Boulder County Jail.
Boulder County supports the new HAP emission standards with the exception of the Particulate Matter (PM) limit of .03 lbs/BTU limit, based on Maximum Achievable Control Technology (MACT) for all new boilers, regardless of size. The cost to add the equipment to meet the PM

Standards on the boiler at the Boulder County Jail will be $110,000, which is more than a third of the cost for the biomass boiler by itself. This is a significant impact to the project cost and makes the small biomass boiler option financially challenging.

Commenter Name: William L. Kovacs
Commenter Affiliation: United States Chamber of Commerce
Document Control Number: EPA-HQ-OAR-2002-0058-2799.1
Comment Excerpt Number: 1

Comment: Clean Air Act (CAA) section 112(d) requires EPA to set emissions standards for new and existing sources of HAPs that achieves the maximum degree of reduction while taking into account the costs of achieving such reductions, any non-air quality health and environmental impacts, and energy requirements. The Boiler MACT standards proposed in this rule are significantly more stringent, and more expensive, than the earlier version of this Boiler MACT rule proposed by EPA in 2004. EPA estimates the new Boiler MACT will cost the regulated community—which consists of roughly 13,600 units—$9.5 billion in capital expenditures, $3.2 billion per year in total annual costs, and $2.9 billion in social costs.

When stacked on top of the various other costly regulations already in force or soon to be added by EPA and other agencies, the true cost of the Boiler MACT could be significant. For domestic manufacturers, the cost disparity between doing business in America and doing business “somewhere else” is growing rapidly. Boiler MACT is an expensive rule on its own; when combined with greenhouse gas permits, five to six new National Ambient Air Quality Standards, Clean Water Act expansion, chemical action plans, and the litany of other new major environmental regulations on EPA’s drawing board, the added costs for businesses can be extreme. The Chamber recognizes the role of federal regulation in seeking to assure public health and safety, protecting the environment, providing needed guidance about federal tax rights and obligations, and establishing fair and uniform rules of interstate commerce. Overregulation, particularly in the environmental arena, is a growing problem for a free enterprise system that could and should be focused on creating jobs and lifting the nation out of economic purgatory.

Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 1

Comment: The proposed Boiler Maximum Achievable Control Technology (MACT) rule has the potential to be very costly for NewPage. We have conducted a limited site-specific engineering review to determine the Boiler MACT compliance costs for our U.S. facilities. These preliminary engineering estimates indicate extraordinary capital expenditures and several million dollars in additional annual operating costs. These costs are significant and will put NewPage at a distinct disadvantage as we compete in a global marketplace with other paper producers located in jurisdictions that do not have to comply with these requirements. In order to remain cost competitive with foreign competition, we cannot pass-on these substantial compliance costs.

NewPage is concerned that without significant changes to the proposed Boiler MACT rule, U.S. manufacturing will need to spend billions of dollars to fund compliance requirements at a time of significant economic pressure with a struggling economy. As a result, additional manufacturing facilities will be closed and jobs will be shed. We are very concerned that mill closures may have to be the final fate for some of our facilities unless changes to the proposed rule are made to significantly lessen the financial burden for compliance.

Comment Excerpt Number: 1

Comment: It is obvious to us that the combination of the three proposed combustion rules in concert with the solid waste definition proposed rule constitute the largest rulemaking package from an applicability and impact perspective in EPA's history, with this Boiler/Process Heater MACT (Boiler MACT) rule having the greatest potential impact. The number of facilities and combustion units potentially subject to these rules is staggering. The data and analysis aggregated and developed by EPA is voluminous. The potential capital cost for this rule is estimated by EPA to be $9.5 billion, and industrial estimates are significantly higher. The collateral impacts of such a high cost and the continuing O&M costs will be significant to the affected sources, employment, and the U.S. economy in general when considered against the backdrop of the current economic troubles.

Document Control Number: EPA-HQ-OAR-2002-0058-2950
Comment Excerpt Number: 1

Comment: Forest products is one of the leading industrial sectors in Minnesota, generating over $8.6 billion in revenue and providing more than 36,000 jobs. The American Forest and Paper Association (AF&PA) estimates that the proposed Boiler MACT rule will cost the forest products industry in Minnesota more than $160 million at a time when these companies are working hard to emerge from the deepest recession in our nation since the Great Depression. The estimated cost for all affected boilers in Minnesota is $730 million, including other industrial sectors as well as commercial and government facilities.

We believe that the EPA proposed Boiler MACT rule will severely impact the forest products industry as well as other Minnesota industries and commercial and public facilities. The proposed rule is more restrictive than needed to protect public health and the environment with emission limits so stringent that they are, in some cases, not detectable or achievable. The cost to individual mills could be tens of millions of dollars at a time of fierce international competition and a weak economy.

Commenter Name: Wilson Jones, Jr
Commenter Affiliation: J.W. Jones Lumber Company
Document Control Number: EPA-HQ-OAR-2002-0058-3139
Comment Excerpt Number: 2

Comment: To even try to meet the limits would require expenditures much higher than our business could begin to afford; we will have to close our business.

The impact of this legislation would force the closure of our two mills and the loss of one hundred fifty jobs not including the impact on others in our area. Our two mills combined economic contributions to the economy include payroll of $6 million annually, payments to loggers and land owners for the purchase of logs of $16 million annually, purchases of supplies of $1 million and payments for outside contracted services of $1.7 million each year. In addition we pay local property taxes of $160 thousand each year. Many other mills have greater financial impact.

If the rules are implemented as proposed the forest products industry in our nation will not survive. Much of the forest products industry is comprised of family owned companies that have struggled to just stay open in the economic recession and the depression in the home building and real estate sectors of our nation’s economy. The proposed Boiler MACT Rules will nail the coffin on our industry with significant impact now and in future years on the cost of everything that uses wood and wood by-products.

Comment: One alternative to huge investments in control is to deliberately reduce our allowable production capacity to a level that would make our mill a non-major HAP source, however, this option of reducing production makes our mill non-competitive. We would then be subject only to the area source rules which may also prove to be very expensive for our company. Other alternatives are not any more palatable, but would include major changes in the processes for the sake of eliminating boilers at our site altogether. Again, we are talking about extremely expensive propositions in a down economy.

Comment: The predicted initial costs are astronomical to meet the proposed emission standards, and the millions of dollars it will cost to keep the pollutant controls running will hit industries hard and there is debate whether or not the emission standards can even be met at all. There will be plant closings and job losses that affect communities all over America. With the current economy and jobless rate, this does not bode well, and let's not forgot all the related jobs just to the pulp and paper industry such as logging and trucking. In an ever increasing globalization world, one must not be giving advantages to foreign competitors, many that do not even have to come close to meeting many emission standards that we meet today, so this law will just allow for more pollution to happen elsewhere as outsourced plants go elsewhere and not meet the currents standards that they are meeting in the USA.

Comment: These regulations will tremendously impact North Carolina's economy as our state has the highest volume of boilers in the country. Manufacturers are the backbone of our state's economy and we are concerned that the potential impact of the regulations could be unsustainable for North Carolina's manufacturers. Both small and large businesses are vulnerable to the costly regulatory burdens under the rule, as are municipalities, universities, government facilities, and commercial entities. It is estimated that the rule will cost North Carolina's industry alone $1.46 billion for compliance and tens of billions in capital costs for manufacturers across the country.
This is not the time to impose these sorts of costs on North Carolina businesses, when our state has already lost over 250,000 jobs during this recession. It will be counterproductive to economic recovery efforts to impose a standard that will hurt our nation's local economies which are already struggling to emerge from the recession.

Comment: The costs to individual manufacturing facilities could be tens of millions of dollars in additional capital expenditures. Total capital costs for the forest products industry alone are

estimated at about $7 billion and the costs to all manufacturing operations could range from $20 to $50 billion.
The paper industry is already struggling financially: many large producers have had to shutter or idle plants, permanently lay off thousands of workers, or even declare bankruptcy. Implementing the proposal as published would be devastating financially to many of our citizens, businesses and communities at a time when US unemployment already approaches 10% and our economy risks a double-dip recession — yet provides little, if any, additional public health protection.
As an employee of Graphic Packaging International, Inc. (GPI), the largest US producer of paperboard used in folding carton applications, I am concerned about how these regulations could negatively affect me personally — my job, income, family, retirement, health benefits, etc.

Comment: The impacts this proposed legislation will have on industry is guaranteed to affect the everyday lives of American citizens. Energy costs and costs of goods and materials will rise to cover the installation and operation of necessary control devices. Some companies may send work to overseas locations where more reasonable standards are set. It is even likely that some locations will need to shut down all together, as they will not be able to afford the necessary capital investment. The EPA estimates initial capital costs of $10.0 billion to comply, along with an added annual operating cost of $3,2 billion. The EPA further estimates the social costs of the proposed rule to be $2.9 billion and between 6,000 and 12,000 American jobs. These economic and social costs estimates may be overly conservative. The American Forest and Paper Association estimates the capital investment for all industries could range between $20 and $50 billion and between 70,000 and 181,000 jobs could directly be affected. Ultimately, this bill will unreasonably limit emissions from boilers with a significant cost to American pocketbooks and American jobs.

Comment: Our industry sector has been savaged by the economy and the volatility of fossil fuel prices. It is simply not an option to convert to exclusively natural gas as a fuel so as to maintain a bearable level of regulation. Biomass is a low-HAP fuel and should not be unduly penalized through the NESHAP process. Doing so will result in plant closures, unemployment and further flight of manufacturing operations overseas where the level of regulation is substantially lower. EPA must recognize that the impact of its rules will be increased HAP emissions through additional uncontrolled combustion of biomass and decreased domestic employment. Congress never intended such draconian effects from the NESHAP program.

Document Control Number: EPA-HQ-OAR-2002-0058-2964.1
Comment Excerpt Number: 17

Comment: EPA's own figures from the rule proposal show capital costs to achieve compliance of $9.4 billion and ongoing annual costs of $3.1 billion. This does not include figures for the natural gas and metal process units EPA proposes to subject to a work practice standard. Industry cost estimates are upwards of twice the figures given by EPA. On a per unit basis, EPA's figures show capital costs per boiler to be up to $7.8 million with annual costs per boiler of up to $2.8 million. Many larger facilities have multiple boilers.

In the current recessionary economy, a recessionary situation that does not at present have any clear ending date, cost impacts such as those detailed above, even if EPA's calculations are more correct than the far higher industry estimates, will be sufficient to imperil the operating status of many industrial plants. Hundreds of thousands of workers in the most heavily-impacted industries, among them pulp & paper, steel, and rubber, are represented by USW. Tens of thousands of these jobs will be imperiled. In addition, many more tens of thousands of jobs in the supply chains and in the communities where these plants are located also will be at risk.

Section 112 (d) (2) of CAA requires EPA to take into account the cost of the the standards it sets as it formulates its regulatory approach. In the case of natural gas boilers it clearly has done so. USW strongly urges EPA to look seriously at the significant cost impacts of this proposed rule and reformulate its regulatory approach for the remaining subcategories in a way that substantially reduces this potentially untenable cost impact and ensures the viability of these industries and the millions of jobs and the communities dependent upon them in the current difficult economic situation.

Document Control Number: EPA-HQ-OAR-2002-0058-2933.1
Comment Excerpt Number: 1

Comment: WMC strongly urges federal policy makers to create conditions that will lead to economic expansion and not stifle the industrial and manufacturing vitality necessary to create jobs and technologies that will continue to improve the nation's air quality. Imposing unduly strict mandates on the manufacturing sector will not accomplish any of these objectives.
New and overly stringent standards for industrial boilers will have an immediate and adverse impact on the ability of Wisconsin manufacturers to compete in an international marketplace, and will do so without demonstrated environmental
benefits. Compliance costs associated with these harsh and inflexible proposed rules will be considerable. For example, the compliance cost in Wisconsin is expected to be $680 million, including a $470 million direct hit to Wisconsin's pulp and paper industry alone. We are very concerned that these costs will result in manufacturing job loss at a time when Wisconsin is struggling to regain its economic footing.

Response: EPA acknowledges the comments. The costs of the rule have been decreased through changes to subcategories, emission limits (based on new data, data corrections, and the MACT floor methodology discussed in the preamble to the final rule).

Commenter Name: Tim Hagley
Commenter Affiliation: Minnesota Power
Document Control Number: EPA-HQ-OAR-2002-0058-2829.1

Document Control Number: EPA-HQ-OAR-2002-0058-2953.1
Comment Excerpt Number: 1

Comment: The recent world-wide recession and continuing economic difficulties have created extremely tough circumstances for the coal industry, manufacturers and other businesses in Virginia and the rest of the United States. These entities will be severely impacted by the proposed Industrial Boiler MACT rule standards and Area Source rule standards. As proposed, these standards are much more stringent than is necessary to assure protection of health and the environment from industrial boiler HAP emissions. The potential economic impact of these proposed regulations is also unacceptably severe. There are 92 boilers in Virginia alone that will be impacted by the proposed Boiler MACT regulations. Many of these belong to utilities or other entities that burn coal. The estimated cost of complying with the proposed Boiler MACT regulations in Virginia alone is $930,000,000. Nationwide the cost of complying with the proposed Boiler MACT regulations is estimated to be in excess of $18 billion. Consequently, the proposed Industrial Boiler MACT standards and Area Source rule standards must be extensively revised so that they are tailored to achieve health and environmental protection without requiring unnecessary expenditures of time and resources.

Comment: Our business will be directly and deleteriously affected by the proposed action. This is certain.
We build all types of boilers but the bulk of our work is targeted toward the solid fuel market. This includes coal and biomass units. We believe this will be the end for coal fired equipment altogether. Already difficult, companies will soon find it impossible to decide to improve their competitiveness by investing in a fuel-saving biomass boiler, as the increased capital expenditure will essentially kill many of the projects we have proposed. We are not sure but we could certainly predict that our workforce would be "down-sized"
Without the ability to incorporate this cost-saving fuel alternative, many of these companies will be hastened toward their demise in the hostile business environment we see today. It will be difficult to assess the number of businesses that will not be started, the number that will cease to exist and the number that will move off-shore as a result of this stifling action. At the very time when our country needs all of the breaks it can get to increase employment this action will cause many jobs to just never materialize, others to be lost and speed the day when China's economy overtakes our own. This is certain.

Comment: We have strong concerns about the proposed emissions limits for biomass-powered boilers and incinerators, as no current boiler could meet these proposed standards. Such regulations would harm our vital forest products industry and hurt the prospects for expanding our nation's green energy production and the jobs it brings.
While we strongly support the goals of achieving strong protections for public health and high environmental performance, we are concerned that there will be unintended consequences with the current draft proposal. Without careful reconsideration these regulations may unnecessarily harm Washington's critical forest products industry -- and that of other states in the union -- and our burgeoning efforts to utilize waste wood from the state's forest lands for renewable energy production.
The forest products industry is critical to all areas of Washington State, representing 11% of all manufacturing jobs and playing a particularly important role in rural, timber-dependent communities.
The sector provided over 45,000 jobs in 2005, generated approximately $16 billion in gross business revenue, and paid out over $2 billion in wages and over $100 million in tax receipts. [Footnote: http://www.ruraltech.org/projects/wrl/sfr/pdf/RetentionReport.pdf]

Comment Excerpt Number: 1

Comment: Our business, like many others, encounters many challenges. However, none threaten the continued existence of our business like the proposed Boiler MACT and CISWI rules. Why are these proposed rules a significant threat?
We estimate it will take $45 million in capital to comply. This is equivalent to 4 to 5 years of our normal total capital spend. When taking into account that a portion of our capital must be spent just to maintain operations, the compliance capital is equivalent to nearly 10 years of "growth and improvement" capital. Simply put, the millions we spend to become compliant with the proposed rules will replace investment needed to maintain competitiveness with competitors around the world who are not subject to the proposed rules.

In addition to the capital investment required to become compliant, we estimate that the ongoing incremental annual operating costs of the mandated controls will be in the $4 to $6 million range. We will be unable to pass these additional costs on to our customers as we face European and Asian competition (where the EPA proposed rules of course do not apply).

Comment Excerpt Number: 1

Comment: U.S. Environmental Protection Agency (EPA) regulations proposed for industrial boilers and incinerators as applied to biomass-powered forest products facilities threaten to hurt both the environment and jobs. I urge you to consider instead cost-effective and achievable standards that protect human health.

Families and communities across Missouri depend upon the forest products industry for their livelihood. These are good people who work hard for modest wages across the 14 million forested acres in Missouri. Seventy-four percent of the energy needs of their employing sawmills come from their wood by-products. Woody biomass is not only an affordable fuel, it is also a renewable fuel that is lower in greenhouse gas emissions than alternative energy sources like coal-fired electricity or propane fired boilers. Those operations that do not use their own woody byproducts sell them to others, providing up to 15% of a sawmill's income. This value as a fuel or income source is often the difference between profitability and layoffs or closure.

Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 1

Comment: The refinery location in the USVI results in several major differences from most mainland refineries and raises issues that are unique, but similar to those facing other remote and island major sources. HOVENSA's St. Croix refinery does not generate enough refinery fuel gas to meet all of its energy needs, and does not have access to a natural gas pipeline, as do all but a few mainland refineries. HOVENSA has no economically practical alternative to using residual fuel oil for an energy source, because the use of high cost distillates would have devastating economic impacts on HOVENSA. Equally important, the island location and the lack of a local reliable electricity grid or water supply mean that HOVENSA must be entirely self sufficient for steam, electricity and desalinated water. This magnifies the effect of Boiler MACT on HOVENSA, because HOVENSA must build and operate the utilities that most other major sources have access to by virtue of their location.

Comment: South Carolina industry faces a withering global economic slump and fierce competition from overseas manufacturers. Therefore, it is imperative for mandatory environmental controls such as the Industrial Boiler MACT standard to be tailored as closely as possible such that health and the environment are protected without requiring unnecessary expenditures of time and resources.

At a time when our economy is fragile and our country faces almost 10% unemployment, the government is adding a significant layer of costs for industry that will close additional manufacturing operations and businesses, and cost thousands of additional jobs by setting limits that are sharply below health-based protection thresholds.

Comment: Cost and jobs implications of the Boiler MACT
We cannot emphasize more forcefully the need to the EPA to completely re-think this rule. As written, it threatens countless companies to spend millions of dollars per boiler and many companies have multiple boilers – all without any financial benefit and at a time they can least afford it. This means that when companies are forced to spend capital on projects that do not create value, there is less capital available to hire workers, invest in energy efficiency, R&D etc.

As currently crafted, the Boiler MACT will result in a combination of undesirable outcomes including: enormous unproductive use of limited capital without financial benefit, higher operating costs that impact global competitiveness, increased annual fuel and electricity costs, less facility operating flexibility, the shutdown of the entire facility (not just the cogen unit), and if they shut down their cogeneration facility, higher electricity costs and net emissions.
In this fragile economic recovery, it is deeply troubling to consider the combined effects of tightening the National Ambient Air Quality Standards, Regional Haze, regulation of Greenhouse Gases under the Clean Air Act, and this proposed Boiler MACT rule. Companies are very concerned that they will not be able to pass these substantial costs on without losing significant market share to foreign competition.
The manufacturing sector is barely hanging on - running at production rates that are between 50-60% of capacity. As such, many of these facilities are “on-the-margin” which means they are either not profitable or marginally profitable because of the economic downturn. We are enormously concerned that the high costs of this proposed rule will leave companies no recourse but to shut down the entire facility, not just the boiler. This is due to the fact that many manufacturing sites require steam to heat processes and electricity to operate equipment. This is the primary reason that combined heat and power plants / co-generation facilities are so effective. Many of the facilities supply incremental amounts of electricity to the grid which enhances that system. If these shutdown then it will lead to greater dependence on the utility sector and less diversity in how power is supplied. If sites do not need the process steam and cannot afford the controls required by this action and shut down their cogeneration facility, they have no recourse but to buy high emission electricity from their local utility.
To further complicate things, since about 2000, the US manufacturing sector has consistently lost competitiveness versus competitors offshore. This means that the cost of operating in the US is higher than the cost of producing the same product in another country. Clear benchmarks are employment, investment and export/imports. Since 2000, the US manufacturing sector has lost almost 6 million jobs or 32%, investment as a percent of GDP is only about 2/3’s what it has been from 1980 to 2000 and our trade deficit has ballooned. The loss of 6.0 million manufacturing jobs at $48,266 per employee has also resulted in lost payroll of almost $289 billion per year and lost federal taxes of about $38 billion. Sadly, there is no indication that these trends have bottomed out and are beginning to turn favorably.
Despite these gloomy numbers, in 2009, the manufacturing sector contributed about $1.6 trillion value-added to the economy, provides 58% of US exports, employs 12 million people and spends $160 billion each year on domestic R&D. And, there is a growing recognition by Congress that a healthy growing export focused manufacturing sector is critically vital to the future of our nation’s economic and national security. However, to achieve these national goals, it is critically important that the EPA not impose unnecessary costs and must take great care to increase flexibility under this rule.

Document Control Number: EPA-HQ-OAR-2002-0058-2957.1
Comment Excerpt Number: 1

Comment: The WVMA is very concerned regarding the effects of the proposed rule on its members. This proposal is very far reaching and it is estimated that it would affect 1600 facilities and 13,555 boilers including 11,500 gas fired boilers across the country. This estimate includes the following sectors: 350 chemical manufacturing, 250 wood product manufacturing, 150 transportation equipment manufacturing, 125 food manufacturing, 100 fabricated metal product manufacturing, 75 pipeline transportation, 75 petroleum and coal products manufacturing, 75 primary metals manufacturing and 50 educational services facilities.
Not only are the proposed rules overly far reaching, the proposed rules will impose very stringent emission limits, monitoring and testing requirements for particulate matter, hydrochloric acid, mercury, carbon dioxide and dioxin. The emission limits for affected units will be based on fuel type and boiler design. To achieve the requirements of the proposed rules, industry will have to install multiple controls and complex monitoring systems. It is estimated that industry will,have to spend over $21 billion dollars in capital costs and close to $50 billion in on-going experiditures to comply with the proposed rules.
The proposed rules potentially impose tens of billions of dollars in capital costs and threaten job losses at thousands of industrial, municipal, university, federal and commercial facilities across the country. We are particularly concerned in West Virginia, where our manufacturing industry has suffered greatly in response to the changes in the regulatory climate and recent recession. It is anticipated that our already stressed members will be severely affected by the proposed Industrial Boiler MACT.

Comment: Initially, it is surprising that the federal government would propose such an extremely stringent, costly rule that will undoubtedly stifle industrial growth and operations at a time when the economy is so dismal. The national unemployment rate continues to hover around 10%, with the manufacturing sector and supporting industries being amongst the hardest hit. The impact from this rule, especially during these difficult economic times, may prove to be unsustainable; further eroding manufacturing operations and the jobs they create, as costs to individual facilities could easily be tens of millions of dollars. Since similar regulations are not being imposed anywhere else in the world, U.S. manufacturing will be put at an even worse competitive disadvantage. To further compound the situation, manufacturing in this country will become more expensive which will result in our exportation of jobs and pollution to other countries where less stringent requirements apply and dirtier fuels will likely be used to make the same product. Accordingly, any decrease in emissions resulting from this rule will be more than offset by uncontrolled, increased overseas manufacturing along with the emissions associated with shipping those foreign goods from the point of origin to the United States.

Response: The EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs. The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). The analysis did not show large changes in production, prices, or imports.

Comment Excerpt Number: 1

Comment: The domestic market for newsprint has declined from 10 million metric tons in 2001 to just 4.8 million today. In 2009, Ponderay Newsprint Company experienced market downtime, and employee benefit and headcount reductions. It has been estimated that the proposed Boiler MACT standards would require a $5 million modification to the fluidized bed boiler that cost $8 million to install and that already has Title V-approved pollution control equipment.

EPA has the legal discretion and technical justification to substantially reduce the burden of the standard, while still providing ample protection to health and the environment, and we urge you to do so.

Comment Excerpt Number: 1

Comment: Wisconsin's pulp and paper industry faces a challenging global economic slump and fierce competition from overseas manufacturers. This situation has existed for the past ten years. Mills in Port Edwards, Niagara, Neenah, Menasha, and Kimberly have closed during that time. In the last ten years paper industry employment in Wisconsin has dropped from 52,000 to 32,000. That's over $1 billion in annual wages lost.
We are concerned that compliance with EPA's proposed boiler MACT standards will be extremely expensive, if compliance can be achieved at all. EPA's estimated capital costs of $9.5 billion, a staggering estimate in its own right, appears to be low. Industry capital cost estimates for the forest products sector alone are estimated to be $6.8 billion. The estimated costs for Wisconsin are $680 million, with $470 million born by the forest products industry.

Commenter Affiliation: Industrial Energy Consumers of America
Document Control Number: EPA-HQ-OAR-2002-0058-2752.1
Comment Excerpt Number: 2

Comment: The EPA must not underestimate the seriousness of our concerns. We have solicited comments from a few of our companies of their estimated cost of compliance. The survey makes it clear why we are concerned.
1. A food processing facility: The cost of compliance for their biomass conversion cogeneration facility is $7 . 5 million. If that becomes the actual cost, consideration would have to be given to shutting down the plant and buying electricity from a utility which would increase their electricity costs and net emissions.
2. A chemicals and paper producer: The capital cost estimate for all US facilities are $600 million plus higher operating costs. That does not include costs associated with the issue of the "Definition of Solid Waste rule". They said that low-margin facilities could be closed rather than spend a lot of capital.
3. A food processing facility: Estimated capital costs for each of their three locations to be between $17 and $41 million and an increase in operation costs of $20 to $37 million over 20 years.
4. A paper producing company: Engineering estimates indicate capital expenditures of around $48.5 million to $116 million plus $1.82 million to $6.5 million in additional annual operating costs. They said these costs are significant and have the potential to put this company at a distinct disadvantage as they compete in a global marketplace. The impact of these costs, will put mills and jobs "at risk" when costs exceeded mill's cost-ofproduction by more than a sustainable amount and cash flow turns negative.
5. A chemical company: The company uses its boilers to self-generate power and steam by combined heat and power that delivers energy and efficiencies well above those achievable by

electric utilities. Estimated capital cost of $97 million to retrofit more than a dozen domestic boilers plus additional control of acid gas emissions add an additional $200 million of capital expenditures. The operating and maintenance costs are estimated at approximately $24 million per year.
6. Aspecialty chemical manufacturer: The Boiler MACT is going to cost about $8 million in capital costs and a minimum of $1 million of annual operating cost going forward.
7. A manufacturer: Capital cost estimate of $10 to $30 million and operating cost in the range of $2 to $ 5 million annually. The loss of dual fuel negotiating position would jeopardize the current favorable transport fee for natural gas of $450K per year and increase costs up to $1.65 million dollars per year. Also, the MACT cost could cause them to retire one boiler and purchase electricity from an electric utility, increasing their electricity costs and resulting in higher emissions.
8. A chemical and paper producer: Total capital cost for the 4 facilities is estimated to be $26 to $40 million plus higher operating costs.
9. A commodity and specialty chemical company: Total capital costs for three boilers are $100 million with increased operating costs of over $1 million annually that puts the jobs of 500 employees at risk. With the health based compliance alternative, the capital costs would drop to about $20 million.
On top of all of the above, this rule will result in significant fuel switching from coal, a reliable, low cost and low price volatile fuel, to natural gas, a high cost and very price volatile fuel. According to the EIA, the average cost of Appalachian coal from 2000 to 2008 was only $1.48 per mmBtu while natural gas was $6.10 per mmBtu - four times more expensive than coal. Natural gas is also the most volatile commodity in the world. The charts at the end of this report illustrate that natural gas is more than twice as volatile as coal which results in higher costs for industrial consumers.

Comment Excerpt Number: 2

Comment: Hampton has done a significant amount of work evaluating the proposed rules and emission limits and engaged the services of consultants to determine the costs for infrastructure modifications necessary to meet the proposed standards. Our consultants used actual source test data from our boilers, fuel analysis, and obtained estimates from emission control vendors. If the proposed standards for HCL, Mercury, and Dioxin/Furans remain as they are in the proposed Major Source rules, Hampton will be faced with capital improvements in excess of $10 million, with at least $2.5 million dollars in additional annual operating costs. Our customers, including Home Depot and Lowes, are not going to pay us any more for our lumber to reimburse us for these costs. They may simply decide to purchase less expensive lumber from a supplier outside of the United States.

In the past five years, Hampton and our employees have already had to make significant financial sacrifices to continue to operate our mills and modernize equipment to remain a viable company. Soaring health care costs, rising fuel prices, and the global housing recession all create very challenging times ahead. The news regularly reports the curtailment or the sale and demolition of sawmills throughout the United States and Canada. I believe that the impact of the regulatory burden and financial expenditures from your proposed regulations will cause more mill closures and loss of jobs in rural communities in Oregon and Washington.

Comment: In the past 15 years, many paper mills have closed across the country due to economic conditions, including some here in Georgia. Others in Georgia, North Florida and many other states are barely hanging on. Some mills have been down almost as much as they have operated in the last 2 years. Even when a facility has not shut down, it may have reduced its operations. Our company shuttered one paper machine in 2005 that cost union jobs. The paper industry competes in a global market place, and if costs are increased unnecessarily, we cannot succeed. My co-workers, my family, and I are increasingly anxious as we worry about the future of our industry and our jobs. Other good paying jobs are hard to find, especially in the rural areas where we operate, so when a paper mill, or even a paper machine, is shut down, the impact to a family due to job loss is immense. Our communities also suffer when mills close – the tax base shrinks, loggers lose their primary customer and other area businesses that support the mills lose a large part of their sales. And with the loss of jobs often comes reduced health care benefits, which carries a far greater public health risk than the emissions from an already well controlled boiler.

Comment: If dry biomass combustion units are included in a generic biomass category, many (if not all) of the remaining domestic operators will be forced to make a decision: either switch to package natural gas boilers – if natural gas is locally available – or discontinue domestic operations and send production overseas.

In today's economic climate, no furniture manufacturer will elect to invest significant capital and commit to increased operating expenses to install a control device of the type that would be required under the rule as written. We will use a typical North Carolina wood furniture manufacturing facility to illustrate the projected costs and negative issues associated with the rule as proposed. This facility operates two dry wood-fired boilers rated at 46.7 MMBTU/hr each, typical of the smaller boilers operated by our industry. The boilers provide process steam heat for the finishing line drying ovens and space heat for the multiple buildings that comprise the manufacturing facility. Total wood fuel consumption for the combined boilers is approximately 12,000 tons per year.

In the preamble to the proposed rule, the EOPA states that MACT for a boiler like the one at our example facility will comprise a fabric filter (for metals) with carbon injection (for dioxins and furans) plus a wet scrubber (for HCl), plus combustion improvements or a CO catalyst (for organic HAP). Furniture manufacturing boilers rarely have any of these types of control equipment, and the example facility is no exception. The existing units could not meet proposed MACT limitations as currently categorized, so we will reasonably assume that the EPA is accurate in its depiction of the control devices that would be necessary to meet MACT for the facility boilers. Assuming that a single set of control devices can service both boilers, the projected capital cost for MACT control equipment at the example facility is calculated using the AF&PA protocol as follows: $1,000,000 for a fabric filter (AHFA). $1,000,000 for carbon injection (AF&PA), $4,431,000 for a single wet scrubber (AF&PA).

The total estimated capital cost of $6,431,000 assumes that a CO catalyst will not be required, and that a single set of units can be located to service two combined stacks; operating costs are not included in this analysis. The projected cost of add-on controls will force every wood furniture manufacturer to evaluate discontinuing use of the carbon-neutral dry biomass and switching to the fossil fuel natural gas (assuming natural gas is available at the facility location). Instead of recovering energy from the dry biomass, it will probably be landfilled. Based on today's landfill fees, it is projected that the manufacturer would incur an additional annual cost of $528,000 to landfill the renewable fuel. In addition to the landfill fees themselves, the manufacturer would incur additional annual costs of $137,000 to transport the fuel to the landfill. Replacing the annual heat value in 12,000 tons of dry biomass would require 192,000 dekatherms of natural gas. At the current local spot market price of $5.50 per dekatherm, the additional fuel cost for natural gas would be approximately $1,100,000 per year. The resulting total annual projected cost of compliance for this facility would be $1,765,000, not including one-time costs associated with boiler refitting for natural gas and construction to provide gas line access to the facility.

The ultimate result of the proposed rule will be to force this facility and many others like it to shift production and jobs overseas.

It is impossible to avoid the conclusion that the proposed rule would have a profoundly negative effect on the wood furniture manufacturing industry. However, the negative effect goes beyond our industry alone and directly contradicts two key initiatives of the current administration: controlling greenhouse gas emissions, and decreasing our nation's foreign trade deficit.

Comment: In 2006 the state energy freedom fund provided $6 million to the Grays Harbor PUD to invest in a new biomass boiler used by the Grays Harbor Paper Company to generate process steam for the 100% recycled green paper plant and electrical power for the PUD. [Footnote: http://www.commerce.wa.gov/DesktopModules/CTEDPublications/CTEDPublicationsView.aspx?tabID=0&ItemID=6698&MId=863&wversion=Staging]
In 2009 the Port Townsend Paper Company received a $2 million dollar stimulus grant to upgrade its biomass boiler. This grant is being matched by $2 million in private funds generated by other energy saving projects in the mill. This boiler is now a part of a proposed $55 million cogeneration project that will provide the equivalent of 35 construction jobs for one year and will create 30 new jobs. In addition, it helps sustain the 290 permanent mill jobs.
Also in 2009, the Nippon Paper Company in Port Angeles received a combination of loans and grants of $2 million to support a planned $71 million investment to replace an existing steam boiler with a biomass boiler retaining 234 permanent jobs and adding 10 temporary jobs. [Footnote: http://www.commerce.wa.gov/site/1345/default.aspx]

A 2009 state study on pulp and paper boilers showed great opportunities for reduced fossil fuel usage and increased renewable energy production – but old boilers will need to be upgraded. [Footnote: http://www.chpcenternw.org/NwChpDocs/Pulp_and_Paper_EE_Boilers_and_CHP_092009.pdf]

With the capital costs involved and the current state of the market, it would be unfortunate if limited capital resources went into short term investments to meet unattainable standards rather than a longer term strategy of investing in aging infrastructure that can continue to create jobs and meet core business objectives while increasing renewable energy generation and environmental performance.

Comment: A single unifying theme lies at the heart of our comments on the proposed Boiler MACT rule — the proposed standards are far more stringent than needed to assure protection of health and the environment from industrial boiler HAP emissions and to fully meet EPA's obligations under the Clean Air Act. During the recent severe economic downturn, Boise was forced to close a pulp mill and two uncoated freesheet paper machines and indefinitely curtail operation of a newsprint machine resulting in about 430 direct jobs lost or about 9% of our workforce. Further economic pressures are expected due to fierce competition from overseas manufacturers as well as an onslaught of regulatory activity Therefore, it is imperative for mandatory environmental controls such as the Boiler MACT standard to be designed such that human health and the environment are protected without requiring unnecessary expenditures of time and resources.

Comment: EPA's stringent standards will have negative consequences on the beneficial use of secondary biomass materials, requiring significant investment and operating costs on biomass-to-energy plants that already meet health-based standards. These plants use forest, agricultural and urban-derived wood residues to produce renewable energy, managing materials that would otherwise be landfilled or open-burned. The plants in California already meet the State's stringent health-based toxic air emission standards. Take, for example, Covanta Energy Corporation's Oroville, California facility which combusts urban demolition wood and agricultural wood and residues, producing 20 MW of renewable electricity. The plant employs 24 people from the surrounding small communities and contributes $13 million dollars annually to the local economy. Since 1987 the facility has been subject to California's AB 2588 Air Toxics "Hot Spots" Program which requires assessments of the health risks of emissions of hazardous or toxic air pollutants. The AB 2588 program provides for the calculation of the cancer, chronic non-cancer, and acute non-cancer risks due to emissions from any specific facility, based on measurements of the toxic emissions from that facility, using an approved methodology, with the comparison of the results to established thresholds of acceptable risk. This program, a "Health Risk Assessment (HRA)," has been successfully and effectively employed in California for over two decades. Recently, the Butte County Air Quality Management District (BCAQMD) reported the results of its AB 2588 assessment for the Oroville facility, indicating a potential cancer risk of 0.42 in a million and chronic and acute hazard indices of 0.005 and 0.003 respectively.[Letter from David J. Lusk, Senior Air Quality Engineer, BCAQMD to Francisco Barriga dated March 12, 2010.] Cancer risks of less than one in a million and hazard indices of less than one are deemed acceptable by the BCAQMD. Risks are also below EPA's acceptable carcinogenic risk threshold range of 1 to 100 in a million. As this example shows, EPA's proposed standards would impose unnecessary and costly emission reduction requirements on biomass-to-energy facilities that currently meet applicable health-based standards.

Comment: Most of our State's industries are working hard to keep their plants open and keep their people employed in the current sagging economy. With unemployment figures hovering around 10%; federal, state, and local governments struggling to maintain fiscal stability; and severe limitations on capital project financing; it is difficult to imagine a more inopportune time for EPA to be imposing such a costly rule.
MCIC supports efforts to address serious health threats from air emissions and believes EPA can craft regulations that sustain both the environment and our competitive position in the world marketplace, while maintaining jobs for the more than 500,000 men and women that are currently employed in manufacturing here in North Carolina. Unfortunately, implementation of EPA's proposed Boiler MACT, as currently proposed, will work at odds with our collective efforts to reverse the current trend in job loss.

Comment: EPA's proposed rules also threaten the ability of struggling families and communities to protect and create jobs. Many parts of rural Missouri, ideal places for the growth and use of biomass, are struggling mightily in the current hard economic times. Rural workers just cannot handle more bureaucratic and expensive regulations from Washington that kill jobs instead of create them. Experts estimate EPA's proposed regulations will cost the forest products industry $7 billion. Killing just one job unnecessarily is not only unfair to struggling workers, it is unconscionable. The administration can hardly claim it cares about job creation if it finalizes regulations as proposed by EPA in this case.

Comment: If liquid-fired sources in locations without a natural gas supply are not exempted from the proposed BPH rule emission standards and allowed to follow an alternative work practice standard, Tesoro would likely not be able to continue operating its Kapolei Refinery. The closure of this refinery would make the fuel supply to local electrical generation plants less dependable, which could affect both the availability and the price that consumers pay for power.

While motor fuels could potentially be transported from the mainland to supply Hawaiian consumers, the added transportation costs would make those fuels more expensive. Tesoro is also a major fuel supplier to military installations in Hawaii. The cessation of refinery operations could adversely impact the fuel supply for military operations in this region.

Comment: EPA has inappropriately used opinions of selected experts in an economic analysis

In this RIA as in many recent RIAs where EPA considers the benefits of PM reductions, EPA used the results of an Expert Elicitation (EE) effort (Roman et al., 2008) effort as a direct input for the critical CRF for chronic mortality to quantify the economic benefits of PM reductions. First, it is inappropriate to substitute the opinion of any individual expert for actual scientific data or fact for use in a quantitative economic assessment. Second, the EE published by Roman et al. was sponsored and administered by EPA, introducing a potential policy oriented bias. As described below, the process used to select the experts and to elicit these opinions was clearly biased.

Our view on the current status of EE is consistent and supported by the recommendations of the National Research Council Committee on Improving Risk Assessment Approaches (CIRAA), a committee commissioned by EPA for the purpose of providing advice on improving risk assessment at EPA (NRC,2008). In the chapter on uncertainty and variability, the CIRAA express serious concerns with both the methodology and use of EE. This discussion was provided in the context of the specific EE report on PM which the Committee used as an example to express their concerns. This text appears on pages 93-95 of the report.

First, the CIRAA did not consider the information from the EPA PM EE report to be useful for weighing risk management options.

"Expert elicitation can provide interesting and potentially valuable information, but some critical issues remain to be addressed. It is unclear precisely how EPA can use this information in its risk assessments. For example, in its regulatory impact analysis of the National Ambient Air quality standard of PM2.5, EPA did not use the outputs of the expert elicitation to determine the confidence interval for the concentration-response function for uncertainty propagation but instead calculated alternate risk estimates corresponding to each individual expert's judgment with no weighting or comparing of judgments (EPA, 2006). It is unclear how that type of information can be used productively by a risk manager, inasmuch as it does not convey any sense of the likelihood of various values, although seeing the range of commonality of judgments of individual experts may be enlightening."

The CIRAA expressed serious reservations concerning the underlying cognitive tendencies that influence expert judgment and which cannot be accounted for. The reservations expressed by CIRAA are listed below, along with our comments on how they apply in the case of the EPA EE effort.

availability: the tendency to assign greater probability to commonly encountered or frequently mentioned events

EPA has placed high importance on chronic PM mortality in previous NAAQS reviews. The expert EE panel members were clearly aware of this fact, thereby introducing a bias to assign a higher probability to a commonly mentioned event.

anchoring and adjustment: the tendency to be over-influenced by the first information seen or provided in an initial problem formulation

In previous PM NAAQS reviews, EPA placed high importance on the results of the ACS study, a fact clearly known to the panel, especially since the panel included a number of co-authors of this study. EPA introduced further bias by emphasizing the ACS study in the background materials provided to the expert panel. EPA introduced the ultimate bias when they invited the lead author of the ACS study, Arden Pope, to make a presentation during the EE deliberations. The objective of the presentation was to address and dispel any limitations of the study that the experts may have had. All of these activities ensured that the ACS study would receive primary importance in the PM mortality risk estimates, thereby introducing serious anchoring and adjustment bias.

representativeness: the tendency to judge an event by reference to another that in the eye of the expert resembles it even in the absence of relevant information

disqualification: the tendency to ignore data or strongly discount evidence that contradicts strongly held convictions

EPA set up an expert selection process that was designed to maximize the number of experts on the panel engaged in the conduct of observational epidemiologists, with well know opinions on the key questions, which were: 1) are the association's causal (yes); 2) is there a threshold for the effects (no). This was achieved by basing the selection of the initial expert list on the number of publications. It is well known that is very easy to publish, for example, time-series observational air pollution studies. All one needs is access to publicly available air pollution and morbidity/mortality records and the standard programs to develop correlations between the two. Based on the pilot EE for which there was a different spectrum of experts and results, i.e., a higher percentage of those engaged in human clinical or toxicology research, EPA excluded most of these experts, who are known to have a higher tendency to have opinions different that than the "strongly held views". The few people who remained on the final panel with differing views were thereby marginalized, introducing a serious member disqualification bias. EPA then provided a list of studies that did not include those reporting no association between PM and mortality, or those suggesting that threshold for health effects may actually exist, depending on the methodology of analysis used. EPA thereby disqualified these studies from consideration.

belief in law of small numbers: the tendency of scientists to believe small samples form a population to be more susceptible than is justified

Based on review of the various science documents EPA has recently produced for criteria pollutants, we conclude that EPA now assumes that there exists for all criteria pollutants no threshold below which at least some individual may be affected by exposure. We term this the EPA doctrine of "infinite population susceptibility." The new causality scheme EPA has adopted for NAAQS reviews places unqualified high emphasis on the results of observational epidemiology studies of air pollution. These studies report very small relative risks that are 2 to 3 orders of magnitude below those that would normally be required to support causality. EPA continues to confuse these small relative risks reported in the studies themselves from observational epidemiology studies, with larger potential population risks derived from their risk assessment process, which are based on exposure to the general population. Therefore, we conclude that EPA has a near unqualified belief in the law of small numbers.

overconfidence: the tendency of experts to overestimate the probability that their answers are correct. In our view, many of the scientists EPA included on the PM EE effort fall in the category of those inclined to overstate the confidence in observational epidemiology data in general, and specifically, the results of the studies EPA selected to consider in this effort. First, the panel consisted of a high percentage of experts conducting observational epidemiology studies. These panel members have a vested economic and professional interest in promoting these types of studies. We note that many of the panel members have received EPA funding, and EPA continues to provide extensive funding for observational epidemiology research. Second, many of the key studies that EPA selected to focus on were authored by the panel members or colleagues, e.g. trained or worked at the same university. Therefore, these experts were in many cases opining on their own data, or the data of colleagues, introducing a significant bias towards being less critical of the findings, resulting in overstating the confidence in the results.

Given the concerns expressed by the NRC CIRAA on the methodology and use of EE in risk assessment, they argued against using EE results either qualitatively for risk assessment or management.

"Given all these limitations, there are few settings in which expert elicitation is likely to provide information necessary for discriminating among risk-management options. The Committee suggests that it be used only when necessary for decision-making and when evidence to support its use is available."

Response: The primary benefits estimates are derived from epidemiology studies examining two large population cohorts: the American Cancer Society cohort (Pope et al., 2002) and the Harvard Six Cities cohort (Laden et al., 2006). These are logical choices because both studies are well designed and peer reviewed. In addition, EPA estimated the range of benefits derived from an expert elicitation to characterize the uncertainty in the concentration-response function for premature mortality (Roman et al., 2008). In general, benefits estimates derived from the expert elicitation functions fall between results using the epidemiology studies.

Comment: The wood furniture manufacturing industry is especially vulnerable to shifting domestic production to overseas sources. Wood furniture manufacturing has experienced a sustained downturn described by the U.S. Department of Commerce as a “perfect storm” of negative factors related to the housing market, foreign dumping, and a host of new standards (flammability, formaldehyde, finishing material composition, and now the proposed new Boiler MACT rule). Domestic employment in our industry has contracted from 620,000 jobs in 1990 to an estimated 360,000 jobs today, while there has been a 519% increase in wood case goods furniture imports between 1998 and 2007. Between 2000 and 2008 270 domestic furniture manufacturing operations have closed, including 112 plants in North Carolina, 31 plants in

Virginia, and 30 plants in Mississippi. Although U.S. manufacturers in the past maintained near 100% production in the United States, most major manufacturers have now relocated major portions of their manufacturing operations to overseas locations such as China and Viet Nam. The overseas infrastructure is in place to easily incorporate additional wood furniture manufacturing, and economic pressure favors a shift from domestic to overseas employment. The proposed rule will represent a tipping point for remaining domestic manufacturers, and if implemented in this form we expect to lose a very sizeable fraction of remaining domestic production.
Fortunately there is light at the end of the tunnel for those manufacturers who have maintained domestic production, or who have at the very least mothballed rather than disassemble their domestic facilities. The Center for Industrial Studies projects moderate growth of the U.S. furniture industry in 2010, and Furniture Today reports that Industry analyst Jerry Epperson of Mann, Armistead & Epperson is forecasting that U.S. consumer spending on furniture and bedding will rise 3.7% in 2010 and another 7.1% in 2011. Some domestic manufacturers have reported plans to expand domestic production for the first time in several years, however they are waiting to see the outcome of influencing activities such as the proposed boiler rule before committing to the investment in domestic production.

Comment: Our company wants to modernize and become more energy efficient and less dependent on fossil fuels, especially foreign oil. Proposals like this chew up all the available capital so you end up with costly new controls on old boilers, instead of allowing gradual movement forward with new, efficient boiler technology. The best estimates now of the capital required for the proposed rule is $30 million just for our Valdosta Mill– that’s two to three times our annual capital & maintenance budget for the entire plant!

Comment: Requiring existing boilers to retrofit Hg and HCI control technologies, (such as activated carbon injection, carbon beds, or wet scrubbers) and CO control technology, (such as afterburners or catalytic oxidizers) to meet the proposed standards is a burden on these 20 to 25 year old power plants which may lead to the unintended consequences of shutdowns with the perverse result of higher long term emissions. These controls would be expensive, provide very small reductions, and would not likely be cost-effective. Also, note that these power facilities have Power Purchase Agreements (PPM) with the local utility and thus cannot pass on any of these emission control costs to the rate payers. Additionally, they have a very limited amount of profit margin. Therefore, the standards could likely cause the plants to shutdown. In northern California that would be a major issue, since this type of renewable energy plant replaces open burning of biomass. Furthermore, the shutdown of green power plants would lead to replacement with fossil fuel power plants, increasing emissions and diverging from the conservation, recycle, and renewable approach of the current administration and public attitude.

Comment: Based on data available, CBEA believes that the majority of the California biomass plants would be under CISWI or Major MACT sources, subject to the Boiler MACT rule and limitations on the set of five HAPs. Unlike the regulated utilities (Investor-Owned) and publicly-owned utilities (Municipal Utilities and Irrigation Districts, for example), which have the authority to recover costs from the electric ratepayers, the biomass power generation plants which sell power wholesale to these entities operate under set-price long-term contracts that provide absolutely no mechanism for recovery of costs that would be incurred by addition of new emission-control equipment. Therefore, even if added equipment could produce compliant emission levels, such equipment cannot be afforded by the biomass industry, leaving no other alternatives to
shutdown.

Comment Excerpt Number: 10

Comment: As reported by an AF&PA analysis, the forest products industry estimates the cost of compliance with the emissions limitations for biomass boilers would be $3.3 billion in that sector alone. In the preamble to the proposed rule, EPA recognizes that economic burden may justify an alternative compliance method. Because the costs to industry to achieve the proposed rule's very low emissions limitations would be incredibly high and could not be consistently achieved in practice, EPA should revise its approach for biomass boilers to ensure that these boilers are not penalized because they start with a cleaner fuel.

Document Control Number: EPA-HQ-OAR-2002-0058-2774.1
Comment Excerpt Number: 10

Comment: This proposed Boiler MACT regulation is calling for a biomass plant emission standards for the suite of five HAPS, or for CO (in the case of the few plants in California that may be "Area sources,") is unmanageable. Such a limitation would have devastating impacts on the biomass industry. The technology incorporated in converting unmarketable wood material into renewable energy does not currently lend itself to any known retrofits or modifications that would allow for such standards to be achieved. All of the California biomass power plants are currently regulated by the Air Pollution Control District or Air Quality Management District of jurisdiction, and all the biomass plants utilize Best Available Control Technology (BACT) for emission control, under California's typically strict air quality regulatory structure. To the extent that EPA continues on its course to drastically reduce the permitted levels of HAPS allowed, biomass plants will be shuttered. Agricultural residue burning will increase in the Sacramento, San Joaquin, Coachella and Imperial Valleys and during in-forest thinning operations throughout the State. Workers will be unemployed. Ultimately, green jobs will be lost and California's air quality will degrade.

Commenter Name: Allyn Ford
Commenter Affiliation: Roseburg Forest Products
Document Control Number: EPA-HQ-OAR-2002-0058-3163
Comment Excerpt Number: 13

Comment: This rule, as proposed, will cause serious economic damage to Roseburg Forest Products facilities in several states:

Existing Units:

As mentioned earlier, Roseburg Forest Products (RFP) owns and operates wood products facilities in several states. RFP has analyzed the financial impact this rule will impose on its biomass units as a result of this rule; in order to ensure that its estimated costs are realistic, RFP requested a third party to assist in this determination. This analysis has revealed that RFP will be subject to over $48.5 million in capital expenditures for additional control equipment, with additional annual operating costs of over $6.2 million.

To put this in a clearer, more complete perspective, RFP's capital expenditure for just its biomass boilers and their respective annual operating costs borne in each state includes:

California (1 unit):

Capital costs: $3.9 million

Annual operating costs: $500,000

Oregon (6 units):

Capital costs: $36 million

Annual operating costs: $4.7 million

Georgia (1 unit):

Capital costs: $3.7 million

Annual operating costs: $450,000

South Carolina (1 unit):

Capital costs: $4.9 million

Annual operating costs: $576,000.00

When compared to RFP's annual payroll amount of $140.5 million to employ 3,700 people, $48.5 million in additional capital costs with an ongoing annual operation cost of $6.2 million is staggering. Imposing standards as strict and expensive as this on an industry utilizing clean, green energy sources in order to obtain a negligible decrease in emissions will seriously impact our ability to produce product and provide jobs.

New Unit:

In addition to the excessive costs associated with existing units, RFP has determined costs associated with a specific unit that would be considered a "new unit" under the proposed rule. RFP has seriously considered replacing an existing unit with a new unit that would be capable of producing green, biomass-generated electricity according to the Administration's stated goal. After spending quite some time researching what would be required of this specific new biomass unit, we find the costs of complying with the proposed rule shocking.

In order to comply with this rule, a new boiler would need to install:

An ESP $3.19 million
HCI Control injection and
Activated Carbon injection at $1.01 million
CO Catalyst at $0.62 million
NOx Catalyst (NSR req'd) $1.35 million
For a total of $6.17 million

Annual operating costs associated with this proposed new boiler are steep:

1. To meet the proposed rule's mercury standard, the boiler's emissions would need to be reduced by 0.0028 lb/hr. Removing this amount of mercury will require injecting activated carbon at a rate of 50 lb/hr. At the current purchase price (not including transportation costs) the annual cost of activated carbon will be $438,000.00 to remove 23 pounds of mercury.

2. Meeting the proposed rule's HCI standard will require injecting sodium bicarbonate at a rate of 110 lb/hr in order to remove 18 lb/hr of HCI (which originates as salt that has been taken up by the tree). This results in an annual sodium bicarbonate usage of 963,600 pounds, for a total annual purchase price (not including transportation) of $79,500.

A possible alternative for HCI would be to install a wet scrubber at the end of the stack. Not considering what the water quality/permitting implications would be, a system for this boiler would evaporate 77 gallons of water per minute; 4,620 gallons per hour; or 36,960,000 gallons per year. Probably not a good option for our thirsty world.

3. Both of these injection systems obviously place an enormous additional load on the ESP, requiring that it be sized large enough to accommodate the massive load of particulate headed its way from upstream pollution control devices.

4. In addition, CO catalyst is known to have a short life expectancy, needing to be replaced at least every 1 to 2 years. The cost associated with this replacement is $320,000.00.

5. The incremental cost of energy needed to operate all this pollution control equipment is anticipated result in a significant increase over current costs.

6. Finally, where will all this pollution control waste go? Ultimately, it will be placed in a landfill at a cost of approximately $30 per ton or $21,000 per year.

As you can see from the well researched example above, the capital and operating costs on a single unit will be significant. As a result, fewer investments will be made in biomass power generation.

Comment: The use of the Morgenstern et al. (2002) methodology and assumptions to estimate the effect of the proposed rule on employment is improper. The Morgenstern methodology is based on general data in four large industrial sectors during a 12 year period (1979 to 1991) which includes 1990 the date of the Clean Air Act Amendments. Morgenstern's methodology does not identify the direct effects of environmental regulation on employment, it measures the effect of reported environmental expenditures on employment at a time when environmental regulation was in it's infancy. The period studied cannot be considered analogous to this proposed regulation for the following reasons:

During the early years of environmental regulation and the associated environmental expenditures studied, control costs were on the order of $500 per ton of pollutant abated. Today proposed rule has costs of $27,000 per ton of PM abated for existing biomass fuel fired sources, $40,000 per ton of PM for liquid fuel fired sources and $95,000 per ton of pm for coal units.

Environmental regulations in the early days and those costs were directly related to production processes and increases in costs affected all producers in an industry similarly. These proposed regulations affect utility (steam) costs and are not directly attributable to any production process. Costs for compliance will vary greatly across individual industries with little chance for pollution abatement activities or byproduct developments to lessen the costs.

The proposed regulations will eliminate several currently utilized byproduct reutilization programs such as coal fly ash reutilization in concrete because the activated carbon required to control Hg and/or dioxin/furans renders fly ash unsuitable for use in concrete mixes.

The costs for compliance will require much larger capital investments than the process specific regulations which were studied by Morgenstern et al. (2002). The capital investments required under this proposed rule will require financing which may not have been required for the much smaller capital investment required during the period studied by Morgenstern.

Morgenstern studied general cost and employment data in four specific large industries affected by environmental regulation. This regulation affects both large and small industries as well as commercial and institutional entities. These later two affected entities are not subject to the "demand effect" described by Morgenstern because they are not involved in production. Similarly, their operations cannot be subject to a "factor-shift effect" because there are not involved in production and therefore, post regulation production technologies will not have the same impact on employment as in industry. Unlike a production facility complying with environmental regulation of production processes, commercial and institutional entities with boilers affected by the Boiler MACT will not be able to substitute labor for other production inputs as production choices become more flexible over

time as US EPA (and Morgenstern) indicates results in positive job gains. These entities cannot substitute labor for other production inputs because the Boiler MACT affects utility costs and steam production not production costs.

In the years studied by Morgenstern, the United States was a leading industrial nation and under little economic pressure to compete internationally for industrial jobs. However, the advances in the international shipping industry which occurred beginning in the late 1980s and continuing through the present have resulted in international competition for industrial jobs. The US must compete with lower labor costs, lower tax rates and lower environmental costs in other countries competing for industrial jobs. The proposed regulation on industrial, commercial and institutional boilers, puts additional cost pressures on US industries not incurred in other industrializing nations who are competing for the industrial jobs which are jeopardized by the proposed rule.

Morgenstern's methodology assumed large plants bear most of the regulatory costs and this assumption may have been proper for large industries like the pulp and paper, plastics, petroleum and iron and steel industries studied by Morgenstern. This assumption is not transferrable to the Boiler MACT which requires compliance for all affected units and therefore affects large and small industries as well as large and small commercial and institutional entities.

For the above reasons, the Morgenstern et al. analysis is not analogous to the Boiler MACT. All of the above indicates that the economic impact analysis and the regulatory impact analysis conducted for this proposed rule underestimates costs, overestimates benefits and underestimates job losses and as result should be revised with a more reasoned analysis.

Response: The principal argument of the comment is that the data used in the 2001 study, which covered the petroleum, pulp and paper, plastics, and iron and steel industries over the period 1979-91, are not relevant to the proposed boiler MACT. The commenter asserts that the effects found, even if transferrable to the boiler MACT industries, were based on average abatement costs of $500/ton whereas the new regs involve costs as much as two orders of magnitude higher. Further, he argues that 'environmental regulations in the early days and those costs were directly related to production processes and increases in costs affected all produces in an industry similarly.'

While it is true that the costs in this rule are much higher than the ones considered in the study, and there is certainly a possibility of nonlinearities in the employment effects, no evidence of such nonlinearlties is offered. As for the assertion that the cost increases affected all producers in an industry similarly,it is doubtful that this is the case. The plant-specific Census data used demonstrated a remarkable amount of heterogeneity of cost impacts associated with the observed environmental expenditures.

The claim that the industry is starkly different from the four industries studied is not supported. On average the study found an (insignificant) gain of 1.5 jobs per $1 million in added environmental spending. In two capital-intensive industries studied, plastics and petroleum, there were small but significantly positive employment effects which were linked to (pro labor) factor shifts and relatively inelastic estimated demand. Several of the industries studied are covered by the boiler MACT. The fact that advances in international shipping put greater cost pressure on US industry may be true, but it is not clear how large an effect that would have.

Comment: These high costs coupled with adverse environmental detriment will also have a negative consequence on jobs and the economy as well, as few if any businesses would find it possible to comply with such an absurd requirement. In order to avoid this consequence, the proposed rule(s) need to be substantially modified.

Comment Excerpt Number: 34

Comment: Because of the need to dynamically adjust the fuel balance in the refinery and to remain in operation when fuel gas producing units are offline or running at reduced rates, a remote facility must have the capability to burn oil in many of the units at the facility. Similarly, because of the need for spare capacity and redundancy, there are more units to maintain operations, often of a smaller size. The effect is that Boiler MACT will have a disproportionate effect on these remote oil fired facilities. For example, HOVENSA has 23 dual fuel heaters and boilers burning residual fuel.
It should also be noted that these add-on controls will consume power and utilities which must be generated by HOVENSA from additional fuel burning. The increased emissions from the utility demand will, in this case, offset perceived gains from the emissions controls required under Boiler MACT. The magnitude of these power and utility demands might also require the affected remote facility to install additional utility systems (including combustion units), increasing the overall cost of compliance and add more air emissions.

Comment: Due to all the reasons highlighted above and in many other comments to this rule, EPA has proposed rules that violate section 112 of the CAA, are far more stringent than necessary, and are completely unworkable even for the industry leaders. The costs of implementing the proposal greatly outweigh any potential benefits. If put into effect, EPA's proposal would deal another hard blow to the already struggling economy and force some companies to shut their doors. This is not what Congress had in mind when it required MACT Floors to be set at a level "achieved in practice." 42 U.S.C. § 7412(d)(3).

Document Control Number: EPA-HQ-OAR-2002-0058-3220
Comment Excerpt Number: 1

Comment: Forest products is one of the leading industrial sectors in Minnesota, generating over $8.6 billion in revenue and providing more than 36,000 jobs. AF&PA estimates that the proposed Boiler MACT rule will cost the forest products industry in Minnesota more than $160 million at a time when our companies are working hard to emerge from the deepest recession in our nation since the Great Depression. The estimated cost for all affected boilers in Minnesota is $730 million, including other industrial sectors as well as commercial and government facilities. In light of the huge cost impacts, it is imperative that the boiler MACT rule be legally and technically sound, and not result in costs that are unnecessary to protect public health and the environment. We believe that the proposed rule falls far short of this standard.

Response: EPA acknowledges the comments. The costs of the rule have been decreased through changes to subcategories, emission limits (based on new data, data corrections, and the MACT floor methodology discussed in the preamble to the final rule).

Document Control Number: EPA-HQ-OAR-2002-0058-2720.1
Comment Excerpt Number: 17

Comment: Estimates of employment impact derived from Morgenstern et al.: The Regulatory Impact Analysis uses two techniques to estimate the changes in employment due to the proposed rules. The first is a longstanding method used by EPA in many previous analyses. This technique looks at the output decrease in the relevant sectors and uses an estimate for jobs per unit of output to calculate a projected decrease in employment. This "demand effect" technique for projecting changes in employment is described in the Economic Analysis Resource Document issued by the Office of Air Quality Planning and Standards in April of 1999. [Footnote: OFFICE OF AIR QUALITY PLANNING AND STANDARDS, EPA, OAQPS ECONOMIC ANALYSIS RESOURCE DOCUMENT at 5-42 to 5-43 (1999).] It contains an implicit assumption that the result of environmental regulations will be price increases and that these price increases will result in lower sales for regulated entities.

However, this type of employment projection is incomplete. The agency correctly identifies that there are at least two types of employment effects from environmental regulations which are not included in the "demand effect" calculation: the "cost effect" and the "factor shift effect." [Footnote: RIA at 4-6 to 4-7.] The "cost effect" recognizes that, for a given level of output, expenditures on reducing pollution often require additional employees. The "factor shift effect" recognizes that production can be more or less labor intensive after compliance with an environmental regulation.

The size of each of these effects and the direction of the "factor shift effect" are all empirical matters and will likely vary from industry to industry and from regulation to regulation. In order to estimate these effects, EPA uses econometric estimates from a 2002 paper by Morgenstern et al. [Footnote: RIA at 4-7.] This paper estimated the employment effects of spending on environmental policies across a number of industries. [Footnote: Richard D. Morgenstern, William A. Pizer & Jhih-Shyang Shih, Jobs Versus the Environment: An Industry Level Perspective, 43 JOURNAL OF ENVIRONMENTAL ECONOMICS AND MANAGEMENT 412, 412 (2002).] As the RIA recognizes, the point estimates do not perfectly correspond to the analysis that EPA is doing. The range of industries analyzed is not the same and the paper uses older data.

Nevertheless, this technique at least recognizes and has the possibility of capturing effects that the traditional techniques of estimating employment effects cannot. This makes the estimates derived from the Morgenstern paper at least as valuable as the traditional techniques of estimating employment effects. The adoption of this technique by EPA could attract additional interest in this area and encourage economists to publish new studies on the topic with newer data.

Response: EPA acknowledges the comments. The costs of the rule have been decreased through changes to subcategories, emission limits (based on new data, data corrections, and the MACT floor methodology discussed in the preamble to the final rule).

Emission Impacts

Comment: Switching from Coal to Biomass, Preamble IV D

What is the basis for stating that switching from coal to biomass would result in similar impacts on HAP's emissions? What organic HAP's would increase and why would lower non-Hg metallic HAP's not compensate for any increase?

Response: This statement was referring to aggregate emissions, and there was no attempt to compare individual pollutant emissions between coal and biomass. The CO emission factors for biomass are higher than coal for the stoker and FB subcategories and so overall emissions would be higher.

Comment: Balancing CO reductions with nitrogen oxide (NOx) reductions already in place in ozone non-attainment areas
Many states that have been designated non-attainment for ozone, including New Hampshire, have worked diligently over the past 15 years to reduce ozone through the reduction of NOx emissions. Since forcing down CO emissions can result in increases in NOx emissions from fuel burning devices, this current effort to control organic HAPs through reductions in CO may negate the efforts conducted by states to improve ozone levels. NHDES encourages EPA to balance CO and NOx emission levels to achieve optimum boiler efficiency as well as minimize the impact on state's efforts to reduce ozone.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2.

Commenter Name: Jay C. Moon
Commenter Affiliation: Mississippi Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2690
Comment Excerpt Number: 7

Comment: EPA's focus on individual HAPs has resulted in a failure to recognize the critical interplay between emissions controls and emissions of other pollutants. For example, we are concerned that the controls necessary to meet the stringent emissions limitations for CO will result in increased energy usage, with the concomitant increase in emissions of NOx and other pollutants. Further, EPA failed to account for this interrelationship in its economic analysis.

Response: See the Preamble for response. The CO limits in the final rule have been revised to higher limits, and as such the use of CO oxidation catalyst controls will be limited. Limited use of CO controls will mitigate the emissions impact from their use and so was not considered in the analysis.

Commenter Name: Arthur N. Marin
Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 12

Comment: Many NESCAUM states have adopted, or are in the process of adopting, standards for ultra-low sulfur heating oil; it is imperative that EPA's proposed regulations do not impair state efforts to reduce sulfur emissions from these sources. NESCAUM recommends that EPA analyze the multi-pollutant benefits gained by encouraging the use of 15 ppm ultra-low sulfur heating oil and incorporate these requirements, when appropriate, in the final rule. NESCAUM recommends that EPA, at a minimum, create two additional categories of boilers: one for units smaller than 1 mmBtu/hr and another for “limited use” boilers.

Response: The EPA thanks the commenter for their input, but there was not enough emissions data from specific facilities to consider ultra-low sulfur oil as a separate subcategory. If data is provided this topic may be revisited in the future. The commenter had provided only general emission factors for different fuel types which are not considered in this analysis.
The EPA agrees with the commenter about limited used boilers, and a separate limited use subcategory for units operating less than 876 hours has been implemented; see the Preamble for a full response. The EPA has not incorporated a deminimus size threshold into the rule, but expects that many of the extraordinarily small units will meet the definition of a hot water heater. Further, the only requirement for small units is a tune-up and the tune-up is expected to be a relatively simple exercise, for small units this exercise is similar to tuning a home furnace.

Document Control Number: EPA-HQ-OAR-2002-0058-2697.1
Comment Excerpt Number: 5

Comment: BTE facilities required to install an oxidation catalyst to meet the proposed CO emission limit may have space limitations or other engineering constraints which would prevent the installation of the additional control equipment. For example, the temperature regimes at the catalyst placement site may not be high enough for the catalyst to function properly. In this case, additional heat (by co-firing) will be needed to get the exhaust temperature within the required temperature range. This co-firing will result in an increase of NOx and other pollutants and may also trigger NSR in California. ARB recommends U.S. EPA perform a more thorough analysis on the feasibility of existing facilities to meet the proposed standards.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2690, excerpt 7 regarding emission increases from CO controls and the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2 regarding NSR.

Commenter Name: Chris Greissing
Commenter Affiliation: Industrial Minerals Association
Document Control Number: EPA-HQ-OAR-2002-0058-2740.2
Comment Excerpt Number: 9

Comment: This variation will be especially true for low nitrogen oxide ("NOx") boilers which can generate more CO even when operating at maximum efficiency. These boilers may not be able to meet the MACT limits for CO because in order to reduce NOx emissions they operate at a lower temperature and inherently result in more incomplete combustion. Failure to recognize this fact creates a tension between controlling NOx emissions and controlling CO emissions, and likely would result in increases in NOx emissions. EPA should take into account that achievement of lower NOx emissions increases CO emissions in identifying which boilers are the best performers. CO standards should be sufficiently flexible to accommodate the effects of low-NOx boilers. In the alternative, boilers equipped with low-NOx burners could be classified into a separate subcategory.

Response: See the Preamble for discussion of the relationship between CO and NOx. The EPA has not included a separate subcategory for low-NOx boilers, see the response to comment EPA-HQ-OAR-2002-0058-2916, excerpt 2.

Commenter Name: Donald R. Schregardus
Commenter Affiliation: Department of Defense
Document Control Number: EPA-HQ-OAR-2002-0058-2763.1
Comment Excerpt Number: 11

Comment: In the cost benefit analysis, EPA failed to consider the detrimental effects of increased criteria pollutants (in particular, nitrogen oxides (NOx)) as a direct result of employing combustion control technologies for the control of CO.

Extensive data from the boiler community and EPA shows that reductions in combustion-related CO are accompanied by increases in emission levels of NOx. However, EPA states in the preamble at page 32048 that the rule will result in substantial reductions of NOx and all criteria pollutants. Many boilers in the solid fuel subcategories are located in either former or current ozone non-attainment areas and are permitted with strict NOx limitations through various regulatory mechanisms such as New Source Performance Standards or New Source Review to ensure the NOx emissions do not adversely impact State efforts to attain the National Ambient Air Quality Standards (NAAQS). Elevated NOx emission levels that result from the installation of CO controls can place a source at risk of potential violations of existing permit limits. When establishing CO emission standards, EPA should ensure the limits are achievable and do not result in an increase in NOx emissions that violate applicable limits or hinder State efforts to attain or maintain compliance with the NAAQS.

EPA should reevaluate each source used to establish the CO MACT floor to determine the impact on NOx emission levels, permitted NOx levels, and installed NOx controls that will result from limits placed on O emissions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2.

Commenter Name: Melvin E. Keener
Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)
Document Control Number: EPA-HQ-OAR-2002-0058-2824.1
Comment Excerpt Number: 19

Comment: CRWI believes that EPA is overestimating the degree of reductions SO2 that will be achieved by HCI control.

As EPA knows, HCI absorbs readily in water at most pH's. As a result, most wet scrubbers designed to control HCI operate at acidic pH's. On the other hand, SO2scrubbing requires pH's above 8.5 (alkaline). Operating controls for an alkaline scrubber are much more difficult due to the formation of carbonates in the process. This can lead to plugging and more frequent cleaning. For this reason, facilities that wish to control HCI will operate their scrubber at acidic pH's because it will achieve the same results with fewer maintenance problems. Consequently, technology to control HCI will not necessarily control SO2.

Response: No data was available to distinguish between acidic vs alkaline wet scrubbers and their potential effect on emission reduction calculations. Based on available information it is shown that both HCl and SO2 are reduced in proportionate amounts. If a boiler needs to reduce its HCl by 50% to meet the MACT floor, then this same 50% reduction is used for SO2 emission reduction calculations; however, scrubbers are shown to remove 95-99% SO2 and thus the calculations would be low if a scrubber is operated at full efficiency.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 124

Comment: Another potential consequence of increasing excess O2 to minimize CO is increased NOx emissions. Typically, NOx emissions decrease with decreasing excess O2 over the normal operating range (Relationship Figure below, left). Thus, tuning to optimize efficiency also is consistent with low NOx emissions. [Footnote: EPA, 1983. Combustion Efficiency Optimization Manual for Operators of Oil- and Gas-Fired Boilers. EPA-340/1-83-023, Stationary Source Compliance Division, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Washington, D.C.] Raising the excess O2 level to minimize CO would have exactly the opposite effect on NOx.

Single-digit CO levels are likely to be difficult to achieve in many boilers and process heaters via the combustion system. The design, operating and condition characteristics of boilers and process that influence CO emissions vary widely among different units, even within the same design category. While reducing CO to optimal levels is beneficial with respect to energy efficiency and emissions of HAPs, NOx, and greenhouse gases, reducing CO below this level is likely to drive these factors in the opposite direction.

Each boiler or process heater will have its own unique signature profiles of NOx, CO and smoke versus excess O2 because of the design and condition of the unit, burner design characteristics, air in-leakage, the distribution of air-fuel ratios among individual burners in a multi-burner unit, the level and variability of process operation, the type and composition of the fuel fired, ambient conditions and other factors. It is not unusual to find two boilers at the same facility of identical design, fuels and vintage, but with different operating characteristics. Thus, just as it is not possible to recommend a single target excess O2 level for all units, it is not possible to predict what minimum CO level all boilers and process heaters can achieve. Operating a unit at a condition which minimizes CO will almost certainly not be the optimum condition for low NOx emissions and high thermal efficiency. Operating at excess O2 levels higher than the optimum operating range will increase energy consumption and consequently increase emissions of CO_2 and NOx, and offset any reductions in HAP emissions that may be achieved.

[See submittal for graph of typical relationships between CO, hydrocarbons, and efficiency with excess oxygen in practical combustion systems.

Recommendation: Take account of the impact of the proposal on energy efficiency and pollutant generation in determining the CO emission limit that should be imposed.

Response: See the Preamble for response on how we addressed and revised CO limits.

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 146

Comment: The numerical emission limits being considered would necessitate combinations of emission controls that have adverse effects on each other. In other words, the presence of one control technology could prevent a second control technology from operating at optimum performance. As an example, a primary control for Hg emissions involves the injection of activated carbon into the flue gas. The mercury is oxidized on the active sites on the carbon particles. The oxidized form of Hg can then either be recovered by the particulate control equipment or by a scrubber (since oxidized Hg is soluble). The oxidation reactions only occur at temperatures below about 350ºF. The effectiveness of the activated carbon for oxidizing Hg is dependent upon the amount of time that the carbon has to attract the Hg to one of its active sites. The use of activated carbon injection for Hg control is negatively affected by the presence of sulfur trioxide (SO3). SO3 occupies the active sites on the carbon, taking away those sites from the Hg. Even a few parts per million of SO3 can have a significant negative impact on the Hg removal that is achieved by activated carbon injection. Small amounts of SO3 are generated as part of the combustion process for sulfur-containing fuels, even natural gas, while the bulk of the sulfur in the fuel is oxidized to SO2. However, other control devices, such as CO oxidation catalyst or SCR NOx reduction catalyst, will convert an additional percentage of the SO2 to SO3, resulting in poor Hg removal.

It is likely other negative interactions occur, but since the needed combination of technologies is undemonstrated all of those concerns cannot be anticipated or discussed.

Recommendation: Only impose numerical emission limits where the combination of necessary controls is demonstrated and fully evaluated.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2702.1, excerpt 214.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 170

Comment: Stack testing at maximum chloride and mercury levels will result in significant chloride and mercury emissions that would not normally occur, since most boilers and process heaters never actually run maximum chloride and mercury fuels. While the amount of unnecessary, excess chloride and mercury emissions may be relatively small for any one boiler or process heater, the national total will be significant because of the large number of boilers and process heaters subject to this requirement. The claimed mercury emission reductions for this proposal should have been reduced to account for these emissions. In fact, the Agency must show that the excess emissions generated by the testing requirement do not result in this rule increasing national chloride and mercury emissions, as it may.

Recommendation: Estimate the excess chloride and mercury emissions that result from the requirement to perform performance tests at maximum chloride and mercury levels and incorporate those emissions into the record and into the emission calculations associated with this rulemaking. Demonstrate that, considering these excess emissions, the proposal actually results in a net decrease in emissions of these pollutants on a unit by unit basis and on a national basis.

Response: The maximum chlorine and mercury (worst-case conditions) are based on fuels which would reasonably be combusted at the unit and therefore EPA expects that facilities firing “worst case” fuels would capture fuels they would use sometime in the future, instead of solely for the reason of compliance. We would expect that units will use a variety of compliance techniques including purchasing of specified fuel types with a maximum level of chlorine and mercury content in order to remain in compliance with the standard. For calculating emissions reductions the baseline values were based on prior performance testing under these same maximum chlorine and mercury criteria, so emission reduction calculations are based on worst-case conditions. EPA also notes that it is common practice to require performance testing at worst-case conditions.

Comment Excerpt Number: 204

Comment: Claim: The Department of Energy has conducted energy assessments at selected manufacturing facilities and reports that facilities can reduce fuel/energy use by 10 to 15 percent by using best practices to increase their energy efficiency. Many best practices are considered pollution prevention because they reduce the amount of fuel combusted which results in a corresponding reduction in emissions from the fuel combustion. The most common best practice is simply tuning the boiler to the manufacturer's specification.

Comment: Major source typically have energy management systems, so experience at sites without such systems does not apply. No explanation is provided on how EPA concluded that this 10 to 15% number was translated into a nationwide reduction of 1% for major sources and we see no basis for that claim. Furthermore, the cited best practice is not applicable because the rule proposal requires tune-ups to minimize CO, not to tune to the manufacturers specifications. As discussed in our comments on the tune-up provisions, tuning to minimum CO significantly reduces energy efficiency.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3122, excerpt 25.

Comment: Additional Source Constraints
Effects of Putting Multiple Controls in Series on Units.
A.
The limits being considered for Boiler MACT would necessitate combinations of emission controls that have adverse effects on each other. In other words, the presence of one control technology could prevent a second control technology from operating at optimum performance.

A primary control for Hg emissions involves the injection of activated carbon into the flue gas. The mercury is oxidized on the active sites on the carbon particles. The oxidized form of Hg can then either be recovered by the particulate control equipment, or by the scrubber (since oxidized Hg is soluble). The oxidation reactions only occur at temperatures below about 350ºF. The effectiveness of the activated carbon for oxidizing Hg is dependent upon the amount of time that the carbon has to attract the Hg to one of its active sites.

The use of activated carbon injection for Hg control is negatively affected by the presence of sulfur trioxide (SO3). SO3 occupies the active sites on the carbon, taking away those sites from the Hg. Even a few parts per million of SO3 can have a significant negative impact on the Hg removal that is achieved by activated carbon injection. Small amounts of SO3 are generated as part of the combustion process for sulfur-containing fuels, while the bulk of the sulfur in the fuel is oxidized to SO2. However, other control devices, such as CO oxidation catalyst or SCR NOx reduction catalyst, will convert an additional percentage of the SO2 to SO3, resulting in poor Hg removal.

Comment Excerpt Number: 216

Comment: There will be adverse environmental effects for those units that can use wet scrubbers. This is because there are very high water use requirements for scrubbing. Finally, EPA states that 330,000 tons of CO_2 would be reduced under rule. It is not clear where EPA obtained this data or whether the reference should have been to reductions in SO2. This would be similar to the information EPA includes in Table 14. 75 FR 32041.

Response: EPA has adjusted the subcategories to a single solid fuel group that will require less units to install add-on HCl control devices. Further, the Agency has adjusted the assumptions of the analysis to consider dry injection removal at areas that do not have wastewater discharge permits. The reference to 330,000 tons of CO_2 noted by the comment is carbon monoxide emission reductions, see 75 FR 32040. EPA has revised its estimated emission impacts in the final rule.

Comment: Efforts to maximize boiler efficiency, and reduce NOx emissions, have also been accomplished by reducing excess air levels until the point where CO emissions begin to climb. Operation at excess air levels which result in CO emissions in the 100-400ppm range provides the most efficient balance between stack heat loss and lost potential energy from incomplete CO oxidation.

* Reducing CO to extremely low levels will require increased excess air levels which reduce efficiency, increasing the amount of fuel that must be fired and therefore increasing the total mass of other criteria pollutants (i.e. NOx, SO_x, PM, etc.).

In some cases boiler designs have been optimized to provide the smallest possible footprint, leaving furnace dimensions that are just large enough to provide CO burnout to reasonable levels. Thus, very low CO emissions would require a combustion chamber space heat release rate on the order of 50,000 Btu/cubic foot. Very few package boilers have this low of a space heat release rate. Most are in the range of 80,000 to 100,000 Btu/cubic foot. Additionally the design of these boilers by necessity will have some by-passing or leaks from the furnace side to the convection side causing CO quenching.

The chart shows computed NOx and CO as a function of temperature and residence time. Chart shows that for low NOx, the adiabatic temperature must be below ~3,000 deg F. Once all mixing is complete, to achieve 1ppm CO requires 0.01 seconds of additional residence time at 1,900 deg F. This increases to 0.05 seconds of additional residence time at 1,650 deg F and to 0.10 seconds at 1,450 deg F.
Typical industrial package boilers have a total flame residence time of about 0.2 seconds. The exit temperatures range from 1,600 to 2,000 deg F depending on the size of the combustion chamber. The flame mixing typically requires about 0.1 to 0.15 seconds for non-premixed flames, leaving only 0.05 to 0.10 seconds for CO burnout. The range of temperatures in the radial direction varies from 400 deg F at the wall to 2,800 deg F in the center of the flame. To achieve 1ppm CO would require the flame to be very narrow, long and well away from the cool walls to avoid CO quenching (which occurs at ~1,500 deg F).

[See submittal for list of references for graph of NOx and CO vs time, temperature at 10% EA premixed.]

[See submittal for graph of NOx and CO vs time, temperature at 10% EA premixed.]

Comment: Criteria Pollutant Concerns: The Proposed Rule relies on Carbon Monoxide emissions as a surrogate for organic HAP emissions. While this may seem to be a logical and simplified approach, Boilers and Process Heaters must also achieve Nitrogen Oxides emissions limitations. Forcing higher oxygen levels in combustion units to achieve extremely low Carbon

Monoxide emissions limitations will make compliance with Nitrogen Oxides emissions limitations more difficult, if not impossible.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2.

Commenter Name: Dale A. Riddle
Commenter Affiliation: Seneca Sustainable Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2866.1
Comment Excerpt Number: 5

Comment: Seneca's operations will actually decrease the amount of HAPs emitted into our local airshed once our renewable energy plant is up and running. As discussed above, open burning results in substantial increases in HAP emissions as compared to controlled combustion. Seneca will provide 25% of its fuel from sources that otherwise would be burned under the Oregon Forest Protection Laws in the field. In its paper published by Paul Lemieux of EPA's National Risk Management Research Laboratory, Benzene emissions from the open burning of Douglas-fir slash were estimated at 196 mg/kg. This means that by diverting enough slash from open burning to constitute approximately 25% of our fuel needs, Seneca's plant will result in more than a 7-tonper-year reduction in Benzene emissions. Emissions of other organic air toxics, such as styrene and toluene, are similar orders of magnitude higher than the emission rates associated with our controlled combustion in our renewable energy plant and, as noted above, the reduction in motor vehicle trips and the elimination of natural gas in our dry kilns will also reduce HAP emissions, such that our renewable energy plant is estimated to reduce total HAP emissions by more than 20 tons per year.

Response: The EPA thanks the commenter for their input, but the EPA did not have ample time or data to analyze the potential impacts the rule may have on open burning.

Comment: Mercury emission limits for major and area sources will help states meet their Clean Water Act Total Daily Maximum Load's (TMDL) for mercury. Because mercury is a regional pollutant, no state alone can impose air emission limits for mercury to fully address their mercury water quality impairments. In approving Minnesota's TMDL for mercury impairments, EPA agreed that it will use its authorities to address mercury as a regional pollutant and establish standards that will reduce releases of mercury to the atmosphere. The MPCA supports EPA's proposed standards for mercury from major and area source standards, and believes they will significantly reduce outstate contributions to mercury atmospheric deposition in Minnesota.

Response: EPA thanks the commenter for their input.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 10

Comment: Optimizing combustion to minimize CO emissions comes at the price of increased nitrogen oxide ("NOx") emissions. MidAmerican's significant experience with retrofitting low NOx burners with over-fire air on large coal-fueled boilers has demonstrated that optimizing the combustion process to reduce NOx increases CO and, the converse is, likewise, true – when adjusting combustion to control CO, NOx increases. The EPA does not appear to have taken this increase in criteria pollutant into consideration when setting these very stringent CO limits. In conclusion, the Boiler MACT should allow facilities to implement combustion optimization instead of proposing compliance with stringent and, in some instances, unattainable CO emission limits.

Response: See the Preamble for response on how we addressed and revised CO limits, and their relationship to NOx.

Comment Excerpt Number: 15

Comment: In addition, the combustion performance of gas fired boilers strongly depends on positions of fuel nozzles, air damper stroking, burner register positions, etc. In order to attempt to comply with a CO level of 1 ppmvd @ 3% O2 on a 30 day rolling average these adjustments will have to be made more frequently than from an annual tune-up. The operator will have to frequently shutdown the equipment, make these adjustments, and then restart. Such cycles will increase annual emissions because CO is higher during shutdowns and startups. Hourly CO CEMS data from a Gas2 low CO emission boiler at one of our sites was extended to a 30 day rolling average. The following plot shows that it would be extremely difficult to keep such a boiler in compliance even with minimal equipment adjustments. [See submittal for figure "CO Histogram – 30 day rolling average, Boiler 1."]

Note: Each bar represents the % of time that CO is above a certain concentration between 2 and 4 ppmv.

Response: Noting the low CO limits for the Gas 2 category at proposal, the EPA has adjusted these limits to a more reasonable number which should minimize the adjustments and impact on boiler operations.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 16

Comment: The proposed CO Level of 1 ppmv at 3% Oxygen Should Not Be Promulgated Because it will Have An Unintended Consequence to Increase Thermal NOx Emissions. The addition of more fuel to increase the load and combustion source firing temperature may result in a small reduction of CO concentrations from boilers and heaters. However, this same increase is not fuel efficient and will also result in an increase of thermal NOx emissions from this same source. Increasing NOx emissions in order to reduce CO emissions is not a good approach to solving air pollution problems. NOx emissions are a precursor to ground level ozone formation and EPA is currently reconsidering the level for the 8-hour ozone standard. Without doubt, a lower ozone standard will require the reduction of thermal NOx emissions. Thus, EPA should not promulgate a CO level that will in turn cause NOx emissions to increase.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 124 regarding emissions increases and the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2 regarding the impact on ozone non-attainment areas.

Comment Excerpt Number: 2

Comment: * Control technologies – There are 5 different pollutants regulated by Boiler MACT – PM, CO, HCl, Hg and dioxin/furan. The control of these pollutants can directly impact emissions of other pollutants or impact the performance of existing pollution control devices:
o Pollutant interactions – The most notable is the relationship between NOx and CO (and possibly dioxin/furan). The inverse relationship between NOx and CO is well established. The generation of both pollutants is a function of combustion conditions in the furnace – excess air, time, temperature and turbulence. CO emissions are minimized by having high excess air and significant time at high temperature and turbulence. These same conditions maximize NOx emissions. Most industrial boilers control NOx emissions by controlling combustion conditions in the furnace utilizing a combination of techniques including low excess air, low NOx burners, staged combustion, and flue gas-recirculation. The requirement to also control CO emissions may require development of a strategy for controlling one of the two by controlling combustion conditions and the other by back-end cleanup. If it turns out that the most cost effective solution is to control CO in the furnace and NOx by back end clean-up, existing NOx control systems will have to be replaced with SCR or SNCR.
o Interaction Between Control Technologies – Control of Hg and dioxin/furan may require utilization of activated carbon injection (ACI). The additional particulate loading in the gas stream will have to be collected by the PM control device. The net impact on PM emissions won't be known until the ACI system is operational and stack PM emissions are measured.
In these situations, the optimal control strategy would be a staged implementation consisting of installation of new control technology to address the Boiler MACT pollutants followed by corrective action to address the impact on other pollutants or pollution control devices. The time constraints make this impractical and compliance costs may increase as a result.

Comment Excerpt Number: 1

Comment: We respect EPA's job is to protect air quality. However, the existence of biomass boilers to receive woody material means that hundreds of thousands of tons of forest slash is burned in controlled combustion rather than in open burn piles. As EPA research has previously established, routing biomass to boilers has a profound beneficial impact on hazardous air pollutant emissions. For example, in its paper published by Paul Lemieux of EPA's National Risk Management Research Laboratory, benzene emissions from the open burning of Douglas fir slash was estimated at 196 mg/kg. [Reference: Lemieux et al, Emissions of Organic Air Toxics from Open Burning: A Comprehensive Review; Table 6; Progress in Energy and Combustion Science 30 (2004)] The estimated benzene emissions from the controlled burning of Douglas fir slash in a biomass boiler is less than 5 mg/leg. This means that every ton of slash burned in the forest results in approximately 40 times more benzene than had that same ton been burned in a biomass boiler. By adding unduly burdensome regulations that force wood products companies such as ours to stop burning biomass, EPA will cause.the diversion of slash to open burning with the net result being a significant increase in hazardous air pollutant emissions.

Document Control Number: EPA-HQ-OAR-2002-0058-2833.1
Comment Excerpt Number: 2

Comment: We request that EPA carefully consider the attached comments. Future costs for the proposed rules are likely unaffordable and could seriously jeopardize the future operation of TASCO facilities and all other U.S. sugar beet companies. Reductions in domestic sugar production would shift operations to other countries with less stringent emissions control requirements. As a result, net overall worldwide emissions would actually increase as a result of these proposed rules.

Response: The EPA may only consider U.S. emissions when considering emissions impacts from this rule, so while the EPA appreciates the comment, considering worldwide emissions is outside the scope of this rule. See the Memorandum "Revised Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source 2011" in the docket for a discussion of costs specific to the affected US facilities.

Commenter Name: Robert Thornton
Commenter Affiliation: International District Energy Association
Document Control Number: EPA-HQ-OAR-2002-0058-2918.1
Comment Excerpt Number: 4

Comment: Low emissions in one pollutant may negatively affect the ability to reduce emissions of other pollutants. The proposed standards are seriously flawed because they fail to recognize the interactivity of a range of pollution controls. For example, emissions of CO and NOx are inversely related. Reducing NOx emissions leads to increasing CO emissions, while reducing CO emissions leads to increasing NOx emissions.
It appears that of the 14 MACT floor pool sources used to set standards for liquid fuel boilers, 6 of the 14 sources do not have low NOx burners. It is likely that these sources, operating with low CO emissions, had high NOx emissions. Sources that have installed low NOx burners may have higher CO emissions.
The proposed MACT standards put regulated entities in the untenable position of being unable to meet both the proposed MACT standards as well as current standards for non-HAP emissions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2740.2, excerpt 9.

Comment: As a company running several manufacturing plants in an ozone non-attainment zone as well as impacted by PM2.5 non-attainment we are particularly interested in any action that has the potential to increase NOx emissions. Concerns have been raised by the Wisconsin Department of Natural Resources that the pollution control approaches required for other pollutants in the rule may have the unintended consequence of increasing NOx emissions. Tremendous efforts have been made in Southeastern Wisconsin resulting in measurable improvements to the air quality and the state is now on track to comply with both the federal ozone and PM2.5 standards and anything that may set back those efforts are cause for concern.

Response: See the Preamble for response.

Commenter Name: Ted Michaels
Commenter Affiliation: Energy Recovery Council
Document Control Number: EPA-HQ-OAR-2002-0058-2831.1
Comment Excerpt Number: 5

Comment: EPA's pollutant-by-pollutant approach fails to account for the interrelationships among pollutant emissions. Emissions from combustion/air pollution control systems are interdependent – the presence or control of one can affect the control of others. These interrelationships must be considered in order to assure that unit emission reductions are effective for all pollutants, not just one at time. Examples of these interrelationships are: Carbon Monoxide (CO) and Nitrogen Oxides (NOx) – CO is a product of incomplete combustion of organic materials and a function of oxygen levels, temperature, air/fuel mixing (turbulence) in the combustion zone, and residence time. NOx formation is dependent on the amount of fuel-bound nitrogen compounds, air-to-fuel ratio, and flame temperature. Because combustion conditions affect both pollutants the two are interrelated. Attempts to control CO can lead to increases in NOx and vice versa. In California, biomass-to-energy facility operators meet NOx permit limits in part by balancing the combustion process between emissions of CO and NOx with the result that CO emissions are significantly higher than EPA's proposed Major Boiler MACT standards. Attempts to reduce emissions of CO would result in increases in emissions of NOx, leading to an untenable situation. The submittal contains two graphs that plot hourly CEM-measured CO and NOx readings over a ten day period at two stoker-fired California biomass-to-energy boilers – Burney Mountain Power in Burney and Mount Lassen Power in Westwood. The plots demonstrate the inverse relationship between CO and NOx. The third graph shows the same interrelationship using 24-hour average plots over an annual period at Burney Mountain Power.

These concerns are echoed in a report by the Maine Department of Environmental Protection which analyzed CEM and stack test data from 19 biomass boilers, stating "Test data demonstrated the relationship between NOx and CO. As NOx levels increased CO levels decreased and vice versa."[Maine Department of Environmental Protection, "Carbon Monoxide Variability in Maine Wood Fired Boilers, February 2010, page 2. Attachment to letter from James P. Brooks, Bureau Director, State of Maine Bureau of Air Quality to James Eddinger, USEPA, February 4, 2010.] The Maine DEP stated "We are also concerned that EPA may develop standards that do not take into account the NOx controls required for many of the Maine facilities and the effect that controlling for CO, which inversely affects NOx, as well as other pollutants."[3 Letter James P. Brooks, Bureau Director, State of Maine Bureau of Air Quality to James Eddinger, USEPA, February 4, 2010.] See Attachment 1 which includes both the Maine DEP report and letter.

Nitrogen Oxides (NOx), Total Particulate Matter (PM), and Opacity – Selective Non-catalytic Reduction (SNCR) is frequently used for combustion source NOx control. SNCR involves injecting a reagent (urea or ammonia) into the furnace where it reacts within a temperature window to chemically reduce NOx. Control efficiency is limited by reagent/flue gas mixing and reaction kinetics. When pushed to higher performance unreacted ammonia "slip" increases which in the presence of SO_3 and HCl in the flue gas forms condensable ammonium sulfate/chloride particulate matter and potentially high opacity stack plumes.

Sulfur Dioxide, Hydrogen Chloride and Mercury – Boiler burning wastes or fuels with significant sulfur and chlorine contents will form mercury species (e.g., mercury chloride) that are easier to collect using carbon adsorption and PM control systems. Boilers burning wastes without sulfur and chlorine emit mercury in elemental form which is harder to collect.

These interrelationships show the technical incompatibility of setting floors on a pollutant-by-pollutant basis.

Response: See the Preamble for responses on how we addressed CO limits, control device interactions, and the pollutant-by-pollutant approach.

Commenter Name: David M. Kiser
Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 6

Comment: Combustion processes have been "tuned" in recent decades to reduce emissions of NOx. NOx reduction technology, i.e., starving the combustion process of oxygen and lengthening the combustion zone to reduce peak flame temperature, is in direct conflict with conditions needed to minimize CO. Current "optimum" combustion conditions or technology cannot achieve the proposed limits on a continuous basis. Attempts to lower CO will increase NOx emissions and result in adverse permitting and environmental consequences.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 124 regarding emissions increases and the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2 regarding the impact on NOx permits.

Document Control Number: EPA-HQ-OAR-2002-0058-2998.1
Comment Excerpt Number: 7

Comment: But unlike natural gas, which is generally stored as a commodity when not consumed, coke oven gas must be flared as a waste gas to ensure a safe environment if not immediately usable at a facility. As a result, creating incentives which cause operators of coke oven gas-fired units to fuel-switch (even to natural gas) would result in significant net emissions increases. That is because the facility would necessarily combust both the coke oven gas (at a flare) and the additional fossil fuel necessary to generate sufficient heat for its operations. Simply put, any standard that creates a disincentive to recover energy from process gases is bad for the environment and thus contrary to the goals of the CAA. Extending work practice tune-up standards to coke oven gas or process gas-fired boilers will ensure that there is no environmentally detrimental incentive to displace coke oven gas or process gas with natural gas or other fuels in the boiler and flare those recoverable energy sources.

Response: EPA has modified the definition of natural gas to be consistent with the boiler New Source Peformance standards, incorporate a fuel specification for hydrogen sulfide and mercury content, and also added an exemption from the rule for boilers that serve as control devices for other MACT source categories. EPA expects these changes will increase the number of gases qualifying as gas 1, thereby reducing the impact that process gases will be flared. We have continued to measure the costs to the remaining gas 2 units, mostly units firing coke oven gas, as costs associated with controlling these units instead of the costs of flaring the gases. EPA does not have the information available to determine how many of the remaining gas 2 units will install control vs. flare the gas and purchase natural gas.

Commenter Name: Allyn Ford

Commenter Affiliation: Roseburg Forest Products
Document Control Number: EPA-HQ-OAR-2002-0058-3163
Comment Excerpt Number: 9

Comment: Additionally, most of Roseburg Forest Products facilities are already required to control NOx emissions at the lowest achievable levels and have no room in their NOx permit limits for combustion modifications to reduce CO, since these modifications universally have an inverse impact on NOx emissions. Roseburg Forest Products questions whether EPA looked at the NOx emission rates of the best performing 12% of sources, from which the CO limits were established, to ensure that those sources are not only compliant with permit limits, but also have demonstrated no significant impact to NAAQS. It is possible that the best performing sources of CO emissions do not struggle with the opposing NOx emission limitations that many other facilities face. EPA is proposing opposing pollutant requirements that will likely lead to facilities being out of compliance with either CO or NOx limits at any given time.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2697.1, excerpt 2.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 13

Comment: CO and NOx emissions are both dependent on the residence times and temperatures of the flue gas in the firebox, but in different ways. Low CO emissions are favored by high firebox temperature, high O2, rapid mixing, and long residence times. NOx is an undesirable combustion byproduct favored by high temperatures, high O2, and rapid mixing via "thermal", "prompt", and "fuel" NOx mechanisms. As CO decreases, NOx increases and vice versa, so emissions control in any fired equipment is a trade-off between the two. See submittal for Figure 8.

For NOx control, designers aim to reduce both temperature of the furnace and time that the reactants and products of combustion stay in the furnace, while ensuring adequate heat transfer to the process or boiler tubes. However, complete oxidation of CO is needed for very low emissions like 1 ppm, which approaches "ideal" combustion. To do this, high temperatures are required > 1900 F and long residence times. However this is impractical to achieve in industrial equipment where large heat sinks quickly quench the flames. Most industrial package boilers have approximately 0.2 second of total residence time in the furnace, of which 0.1-0.15 second is required for flame mixing. The remaining 0.05-0.1 second of residence time is what can be tolerated before the flue gas is quenched by the colder process or boiler tubes. For most boilers and process heaters achieving low NOx emissions, there is insufficient time at temperature to oxidize CO to 1 ppm.

Response: See the Preamble for response on how we addressed and revised CO limits.

Commenter Name: Chris Korleski
Commenter Affiliation: Ohio EPA
Document Control Number: EPA-HQ-OAR-2002-0058-2818.1
Comment Excerpt Number: 20

Comment: Many boilers in ozone non-attainment areas have also been modified to achieve reductions in NOx emissions. The first basic step in controlling NOx emissions, especially industrial sized boilers, is to apply combustion modifications which can result in higher carbon monoxide emissions. It is not clear that the evaluation EPA performed in proposed its MACT rule addresses the necessity to meet NOx requirements or the physical changes that have been made to boilers in order to meet these limits stemming from other EPA rules. In some cases, staging the combustion and increasing residence
time in the- combustion zone could theoretically result in more complete combustion ,c)f organic HAPs. Or in other types of modifications, less complete combustion may be achievable while meeting the NOx requirement. At a minimum, US EPA needs to recognize that NOx requirements are in place for boilers which may impact the ability to meet the proposed carbon monoxide emission limits (refer to discussion on CO emission limits).

Response: See the Preamble for response on how we addressed and revised CO limits.

Commenter Name: American Crystal Sugar Company and Michigan Sugar Company
Commenter Affiliation: Patricia Hansen and Steven Smock
Document Control Number: EPA-HQ-OAR-2002-0058-2970.1
Comment Excerpt Number: 23

Comment: We do have concerns that the proposed rule is overly aggressive. As stated above there is evidence that a significant amount of the data and resulting emission limits need to be closely examined. The MACT floors need adjustment. Failure to do so may result in an impossible situation for nearly all boiler operators. Any reduction in domestic sugar production as a result of the proposed regulations will result in an increase of imported sugar. This has the potential for actually resulting in a world wide net increase in air pollution emissions since the US is a leader in efficient production and few sugar exporting countries have the same level of emission control. The impact evaluation of the rule must include this likely scenario.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2833.1, excerpt 2 regarding emissions from importing sugar and the Preamble for a response regarding limits.

Commenter Affiliation: USEC, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3122

Comment Excerpt Number: 25

Comment: Energy audits/assessments — 1 percent efficiency improvement. The assumed energy efficiency improvement is questionable. The proposal and WA assume that many units are operating inefficiently and that unit owners have not evaluated unit efficiency. This is likely not the case and the assumed efficiency improvement will not occur because the proposal will have the unintended consequence of decreased efficiency because of the CO emission standard. A normal step taken to reduce CO is to increase excess air (oxygen). This reduces unit efficiency because although there is more complete combustion, more heat is exhausted with the excess air. Additionally, a second unintended consequence is an increase in NO emissions because there is more oxygen available to form NO, while in the critical temperature range.

Response: Boiler tune-ups can improve the efficiency of a boiler from 1 to 5%, depending on its operating characteristics. While some boilers may have performed tune-ups there is still a large percent which have not. Using these two factors, an estimated efficiency improvement of 1% is considered a conservative estimate. See the preamble for a discussion on NOx emissions and boiler efficiency as they relate to the CO limit.

Commenter Affiliation: USEC, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3122
Comment Excerpt Number: 36

Comment: CO emission limits and work practice standards. The CO emission standard could result in reduced efficiency and increased NOT emissions. A normal step taken to reduce CO is to increase excess air (oxygen) this can reduce unit efficiency because although there is more complete combustion more heat is exhausted with the excess air. Decreased efficiency results in more fuel burned and increased emissions.

Additionally, NOT emissions can increase because more oxygen is available to form NO„ while in the critical temperature range. Affected units with NOT emission limits may find it difficult or impossible to simultaneously achieve both CO and NO, emission limits. This is especially relevant to those affected units where steps have been taken to reduce NOT emission through low-NO„ burners, flue gas recirculation, etc. If there is a net increase in other emissions, including NO,, the benefits of regulating non-dioxin organic HAPs (using CO as a surrogate) under the MACT are questionable and should be reconsidered.

An increase in NOT emissions will impact ambient air quality and increase social costs. Decreased efficiency will result in an increase in many air pollutants. These negative costs impacts should be included in the cost impact analysis.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 124.

Comment Excerpt Number: 53

Comment: Most boilers are designed to mix fuel and air at an appropriate ratio, and to provide sufficient residence time for the fuel to combust completely. Obviously, these factors are fuel-dependent. A gaseous fuel will require less time for complete combustion than a liquid fuel, which in turn requires less time to burn than a solid fuel. The need for longer residence time is why the radiant section s in solid-fuel fired boilers are larger than for gas-fired units. The size of the boiler is typically optimized to allow for complete combustion, while minimizing the cost of construction materials. If the construction cost were not a concern, a new boiler could be designed with additional residence time to complete the combustion process and minimize CO emissions.

Unfortunately, increasing the size of the furnace is not an option for existing units. For these units, the strategy for reducing CO emissions is typically to raise the level of excess oxygen. The increase in oxygen concentration has two positive effects. First, it acts to overcome poor distribution of the fuel. Second, it increases the flame temperature, which speeds up the combustion reactions, allowing more complete combustion to occur for the same residence time. However, there are a number of negative impacts associated with operating a boiler at higher levels of excess oxygen. Many boilers do not have sufficient fan capacity to run with elevated excess oxygen at the high end of the load range. Therefore, these units would not be able to operate at capacity under this strategy. A site might have to add another boiler to offset the reduction in steam generating capacity.

Minimizing excess oxygen in boiler applications is a key feature for maximizing boiler efficiency. The boiler efficiency is defined by the amount of combustion air that is present, and the difference between the ambient temperature and the stack exhaust temperature. The more air that is heated up through the combustion process, the more heat is lost to the atmosphere, causing the boiler to be less efficient. A less efficient boiler will require more fuel to be fired to produce a given amount of steam. The additional fuel firing results in higher operating costs, and higher greenhouse gas emissions.

Minimizing excess oxygen is also a primary strategy for reducing NOx emissions from a boiler. The NOx formation mechanisms are dependent upon the temperatures in the flame zone, and the stoichiometry. Reducing the level of excess oxygen reduces the peak flame temperature, which reduces the rate at which the nitrogen in the air dissociates. There is less monatomic nitrogen available to be oxidized to form "thermal NOx". Similarly, if there is less oxygen present, the monatomic nitrogen is less likely to be oxidized (and more likely to react with a second monatomic nitrogen to form diatomic nitrogen). This reduces both the amount of thermal NOx, and the "fuel NOx" (NOx that is formed by the release of fuel-bound nitrogen). Therefore, increasing the level of excess oxygen will result in higher NOx emissions.

Comment: Low-NOx burner (LNB) designs for gas-fired boiler applications manipulate the stoichiometry within the flame to minimize NOx formation. These designs establish a fuel-rich zone for the initial phase of combustion, and then add air at a later stage in the outer regions of the flame. In the initial phase, there is not sufficient oxygen available to form significant amounts of NOx, and in the secondary phase, the flame is much cooler, which also inhibits NOx formation. However, these burners often operate with CO emission up to 10 ppmvd in the upper part of the load range. At mid loads, the CO begins to increase near 50 ppmvd, and at low loads, it may exceed 100 ppmvd. These low-NOx burners will not be able to achieve CO emissions as low as 1 or 2 ppmvd. As the EPA is on the verge of establishing a lower ozone standard, many more facilities will likely be installing low-NOx burners.

The data from units used to determine the floor for the Gas1 boilers and heaters were reviewed to better assess the quality of the proposed CO limits. Specific information was obtained for 23 of the 91 units in the floor calculation (about one fourth of the sources). Of the 23 units that were investigated, 7 were no longer in service [We expect that the parent companies have already communicated these shutdowns to EPA as part of their comments.] In addition, the analysis showed that none of the units were equipped with state-of-the-art low-NOx burners, and many were equipped with conventional burners that were more than 30 years old (contrary to EPA's contention in the floor memo that replacement low-NOx burners will result in lower CO emissions). As stated previously, LNB are designed to stage the flame, and as a result have higher CO emission rates. A great majority of these units are smaller process heaters, which are not equipped with combustion controls or O2 analyzers. As such, they are typically operated at higher levels of excess air as a safety precaution, which is inefficient, but does serve to minimize CO emissions.

Response: See the Preamble for response on how we addressed and revised CO limits.

Commenter Name: Jim Griffin

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 55

Comment: The requirements of the National Fire Protection Act (NFPA) specify the minimum total airflow at which a boiler can operate, which is independent of the boiler load. This value is commonly 25 or 30 percent of the total airflow. As a result, boilers that are operating at loads less than 25 percent experience increasing levels of excess air because the fuel flow is decreasing with load, but the air flow remains fixed. The amount of excess air can become sufficiently high that it acts as a heat sink and reduces the flame temperature. The cooling of the flame slows the combustion kinetics, and often produces higher CO emissions. Therefore, low CO emission limits could restrict the minimum load capability of a boiler. Since boilers are often run at minimum load (either in warm standby mode, or due to low steam demand), this results in the boiler "idling" at a higher load than was previously necessary. Obvious outcomes of operating at higher load are increased fuel costs and a relative increase in greenhouse gas and other pollutant emissions.

Response: See the Preamble for response on how we addressed and revised CO limits.

Document Control Number: EPA-HQ-OAR-2002-0058-2845.1
Comment Excerpt Number: 61

Comment: The controls necessary to meet EPA's stringent proposed emissions limitations for CO will result in increased energy usage along with increased emissions of other pollutants.

EPA's proposed CO emissions limit arbitrarily and capriciously fails to recognize the dependency between CO and other emissions, which makes this rule impossible to implement in either process heaters or boilers. Requiring such extraordinarily low CO levels will have an adverse impact on other emissions such as NOx, PM, greenhouse gases (GHG) and even HAPs. Reducing CO to extremely low levels will require increased excess air levels which reduce efficiency, increasing the amount of fuel that must be fired and therefore increasing the total mass of other pollutants (i.e. HAPs, GHGs, NOx, SO_x, PM, etc.). For example, CO and NOx emissions are both dependent on the residence times and temperatures of the flue gas in the firebox, but in different ways. For most boilers and process heaters achieving low NOx emissions, there is insufficient time at temperature to oxidize CO to 1 ppm. As CO decreases, NOx increases and vice versa, so emissions control in any fired equipment is a trade-off between the two.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 124.

Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 79

Comment: The proposed rule, which is a hazardous air pollutant rule, does not actually calculate HAP emissions from gas fired units and the potential reduction as a result of the proposed rule.

Based on a review of the supporting documents of the proposed rule, it appears EPA did not calculate the emission reductions or estimate the benefits associated with the HAP reductions. Failure to provide this information undermines the assessment of rule impacts, cost-effectiveness, and beyond the floor considerations.

EPA needs to calculate the HAP baseline and emissions post rule implementation to properly characterize the rule impact and costs, and to update the RIA.

Response: Emission estimates are provided for CO, THC, VOC, PM, Hg, non-Hg metals, dioxins/furans, HF, SO2, and HCl. It is demonstrated that VOC includes organic HAP, and to the extent that VOC are reduced, organic HAP would be reduced as well. No specific individual organic HAP calculations were estimated.

Secondary Impacts

Document Control Number: EPA-HQ-OAR-2002-0058-0849.1
Comment Excerpt Number: 5

Comment: Biomass boilers should be given special consideration. Biomass boilers are carbon neutral and beneficial to the environment. My mill has two biomass boilers. EPA should encourage the continued operation of biomass boilers. By setting unreasonable limits on biomass boilers, EPA will drive industry towards fossil fuel when EPA should be favoring biomass use.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Document Control Number: EPA-HQ-OAR-2002-0058-0849.1
Comment Excerpt Number: 2

Comment: The Boiler MACT rule needs to be fixed. The rule, as proposed, will actually discourage industry from using biomass over more traditional fossil fuels or natural gas.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Thomas J. Christofk
Commenter Affiliation: Placer County Air Pollution Control District
Document Control Number: EPA-HQ-OAR-2002-0058-1598.1
Comment Excerpt Number: 1

Comment: The Placer County Air Pollution Control District does not support the MACT standards for biomass boilers for major and area sources as proposed. The proposed biomass boiler MACT standards have not been properly determined and will lead to adverse outcomes. Compliance would require the addition of "beyond the floor" control techniques that are not cost effective or required to protect human health or the environment. Some may even result in higher NOx emissions. Biomass boilers in Placer County (and throughout California) are already subject to existing regulatory permitting and inspection programs which ensure that boilers do not cause adverse impact to human or environmental health or degrade local air quality. Closure of existing plants and prevention of new plants would lead to significant increases in air emissions, as biomass wastes will be open burned or land-filled. Additional fossil fuels will need to be combusted to make up for the biomass energy.

Response: See the preamble for revised emission limits.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute and National Petrochemical and Refiners Association
Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 3

Comment: The indirect consequences of some of these proposed requirements also were not included in the information provided to OMB. For instance, under the control schemes evaluated by EPA and used as a basis for their cost and burden estimates, the proposed CO limits for gas and oil would require increased fuel and electricity use and, as a result, increase CO_2 emissions. In fact, emissions of all pollutants other than CO would increase because of this increased fuel use. The low CO requirements proposed here will potentially lead to units being unable to meet the latest NOx emission limits set in other rules (e.g., NSPS Ja) and in State Implementation Plans (SIPs). This interaction calls into question the regulatory basis for those other rules and SIP requirements.

Response: See the preamble for discussion on CO limits.

Commenter Name: Thomas J. Christofk
Commenter Affiliation: Placer County Air Pollution Control District
Document Control Number: EPA-HQ-OAR-2002-0058-1598.1

Comment Excerpt Number: 4

Comment: PCAPCD believes that the standards are not needed to protect human health and the environment, and will likely lead to undesirable outcomes. District biomass boilers have been determined to pose low risk to human health, the environment, and ambient air quality. Existing boilers may be required to add Hg and HCl control technologies, such as activated carbon injection, carbon beds, or wet scrubbers and CO control technology (afterburners or catalytic oxidizers) to meet the proposed standards. These would be expensive, provide very small reductions, and would not likely be cost-effective. The standards might cause boilers to either stop utilizing biomass wastes or shutdown. This would significantly increase criteria, air toxics, and greenhouse emissions because the biomass wastes would be open burned (or land-filled), and additional fossil fuels would be required to replace the renewable energy that is produced by the biomass boilers.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: Flambeau River Papers is a pulp and paper mill that has been in operation in Park Falls since 895. This mill has numerous boilers, the largest of which is the coal and biomass coal-fired boiler, number 6. Number 6 produces approximately 60 percent of the energy needs for the pulp and paper mill on a daily basis. In the four years we have owned and operated the

mill, we have been able to increase the efficiency of the boiler while at the same time decreasing our usage of coal from an historic average of 60 tons a day to being virtually free of coal today. The mill's previous owner's reliance on fossil fuels is truly what drove the mill into bankruptcy back in 2006. Sky rocketing fossil fuel costs, including coal and natural gas, increased the energy costs from a budget of approximately $400,000 a month to over 1.4 million a month. It was with this in mind that we made the commitment to ourselves, and the 13 employees at the mill, that we would become the first pulp and paper mill in North America to be fossil-fuel free. Because of that commitment, Flambeau River Papers has been able to reduce its carbon footprint by approximately 92,000 tons a year since 2005. This is another reason why we invested over $3 million to develop a new industrial biomass fuel boiler that burns at approximately 10,000 Btu's per pound to replace the coal that was used in the number 6 boiler in Park Falls. And it's the reason we are continuing to partner with the Department of Energy on a second generation biofuels project that we built next to the pulp and paper mill, and it will produce 17 million gallons of second generation transportation fuels, electricity, and have enough steam left over to replace 00 percent of the natural gas needs at the pulp and paper mill. With Flambeau River biofuels heat sinqed, the pulp and paper mill will be the first pulp and paper mill in North America to become fossil-fuel free. At Johnson Timber we utilize a small biomass boiler to produce the heat and steam required for the approximately 147 heating days at this facility. The biomass utilized by this boiler is bark from our manufacturing process. We have used this biomass for heat and steam for over 30 years so we can have that facility be virtually fossil-fuel free as well.
Our current plans to become fossil-fuel free at our facilities and continue to employ approximately 400 people through our organization in the forest products industry, however, is in jeopardy through the proposed stringent Boiler MACT rules. The pulp and paper mills in North America have been utilizing renewable biomass fuels for many decades. Approximately 65 percent of the energy needs in our industry come from carbon-neutral biomass. It would be unfortunate for this proud industry to have to cut back away from carbon-neutral fuel and have to convert to fossil fuels to meet the proposed rules.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Affiliation: See transcript for detailed list of commenters
Document Control Number: EPA-HQ-OAR-2002-0058-1876
Comment Excerpt Number: 32

Comment: The proposed rule would cause many biomass boilers to convert to natural gas because that would be the only option they could afford. If Coastal switched, its annual natural gas cost would be $10 million a year and 150,000 tons of wood fuel would pile up somewhere. If all U.S. softwood panel and lumber producers switched, the annual cost would be $1- to $2 billion, we would consume 1- to 2 percent of total U.S. natural gas withdraws, which would significantly disrupt the natural gas market, and 20 million tons of wood fuel would be piled up somewhere to rot, which definitely wouldn't be green.

Response: EPA is not requiring fuel switching to natural gas in the final rule. Further, based on the data from best performing units in the biomass subcategory several units firing biomass are meeting the final emission limits. Therefore, EPA does not expect all of the units firing biomass to switch to natural gas as a compliance option; as a result, the EPA determined that the estimated landfilled biomass and increased natural gas usage noted by the commenter are overestimated. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Comment: The boilers that are in use in the pulp and paper mills, in this state, have gone predominantly to biomass rather than natural gas or other fossil fuels. We are trying to push for carbon neutrality. We have a great deal of biomass available in Texas for use in our boilers and we are adapting that as much as we can.
We would like the EPA and the other -- both state and federal governments that are responsible for energy policy to pull together and to see if -- if -- make sure that what we do in one area doesn't impair the incentives that are in place for biomass use.
And we would just urge EPA to look at that issue and to make sure that all of these policies are running consistently with each other.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: The proposed regulations will negatively impact the use of biomass fuels for industrial boiler use. The wood products industry has been using clean wood residuals as a primary fuel for decades. In other words, we were green before green was cool. The current administration touts the use of biomass fuels as part of

the new energy policy. On one hand, the USDA has given away over $148 million under the BCAP program for fuels that were already being used and now these regulations will restrict the use of these biomass fuels in the future. Any new business models that may be contemplating the use of biomass fuels may find the cost of the regulation prohibitive. To me this is another case of one body of government not acting in concert with the direction of another body of government.
Conversion of a wood products plant to natural gas is not economically viable. In our case, we have calculated that the increase in operating costs to use natural gas to be $31 million annually. That would be a 34 percent increase in operating costs at a time when the industry has sustained multiple years of losses, and would not be economically sustainable.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: The forest industry has been, and continues to be, the largest consumer of biofuels. The rule as proposed ironically would impede environmental progress that many companies are achieving through greater and more efficient use of carbon-neutral biomass and would force the use of fossil fuels, which is face far less stringent requirements under the proposed rule.
Norbord suggests that the EPA requires this approach to recognize the carbon-neutral contribution of the biomass boilers in existence and ensure that these boilers are not penalized because they used an inherently cleaner fuel from the start.

Response: The carbon emissions from biomass is not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Comment Excerpt Number: 1

Comment: CECONY, as a member of the Clean Energy Group, endorses the comments provided by that group under separate cover. CECONY's individual comments, provided below, focus on the proposed rulemaking's regulation of liquid fuel and the way MACT floor values have been established for liquid-fueled units. Specifically, the Company is concerned with both a perceived deficiency in the data collection process and the adverse impact to Company steam system operations that will likely result from the rulemaking's failure to subcategorize liquid-fueled units. The use of residual oil in the CECONY steam system is essential to the maintenance of that system's reliability. During the coldest winter months, the New York State Public Service Commission requires that limited natural gas supplies be preferentially provided to residential and commercial customers. It is during such periods that the maximum output of the steam system is required for heating, and, consequently, the steam system boilers use residual oil as fuel to increase the availability of gas for residential and commercial use. This ability to use residual oil in the steam system boilers ensures that there is sufficient natural gas for preferred customers and that there is sufficient steam to heat the commercial and institutional buildings within the CECONY district steam system.

Response: See the preamble for discussion regarding subcategory definitions.

Comment: We employ more than 52 Oregonians and hope to be able to expand our employment by at least 40 people directly and an additional 20 people indirectly with the completion of the planned 35 Megawatt biomass electric facility in Klamath Falls.

As a timber company, we will be supplying the wood chips and forest waste to the proposed Klamath Biomass Facility as well as other timber users, which, we are told by the Oregon Department of Environmental Quality, will be subject to this proposed rule.

With the unemployment rate hovering around 9.5% nationally and 14% regionally and with talk of a "double dip" recession and/or a "jobless" recovery, every existing job and every projected new job is precious. This is the wrong time to expand these rules that will increase costs for existing and proposed boilers which may impact existing and new job development.

Development of biomass power facilities will provide for increased forest health and lower the potential for catastrophic wildfires on both public and private land. In a state where wildfires are the major contributor to our carbon footprint, the potential to reduce wildfires, generate renewable electricity and create jobs is a win/win for the environment, forest health, business and the public, in general.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass.

Document Control Number: EPA-HQ-OAR-2002-0058-1874
Comment Excerpt Number: 2

Comment: Our company has, in the past, seriously considered installing new biomass boilers fitted with turbines that can generate clean, "green" power to meet our Nation’s growing demand for renewable energy. Unfortunately, the stringent limits proposed in the Area Source and MACT rule will make projects that are already marginally economical to be that much less so, meaning that in our case, these projects will not occur. This rule will serve to significantly dis-incentivize new biomass power projects, which until now, had been promoted by both State and Federal programs.

We believe that EPA’s goals can and must be reached without the huge regulatory compliance costs that would cripple the industry’s competitiveness and eliminate our economic and environmental contributions. We urge you to reconsider the proposed rule and continue to work with the regulated community to arrive at an effective and workable solution.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 discussing biomass.

Comment: Also, the Boiler MACT is expected to require installation of up to five different air pollution control devices that will conflict with other existing control requirements. EPA should not ignore the practical capabilities of controls and the variability in operations, fuels, and testing performance across the many regulated sectors.

Response: See the preamble regarding revised emission limits and interactions of control devices.

Commenter Name: Randy Stoeckel
Commenter Affiliation: Johnson Timber Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-1975.1
Comment Excerpt Number: 5

Comment: EPA's proposed Boiler MACT can be crafted in a more balanced way that sustains both the environment and good jobs and doesn't hurt our ability to compete against imported products. If EPA were to provide more flexible approaches in the final Boiler MACT rule and appropriately address the diversity of boilers and fuels in use, it could achieve its goal while preventing severe job losses and billions of dollars in unnecessary regulatory costs. I urge you to consider the cost to American companies for a small reduction in controlled pollutants when our competitors or wildfires dump many times more into the earth's atmosphere every hour. Boiler MACT in its current form is pushing the use of Natural Gas. Is increasing the use of fossil fuels really what is intended?

If the money needed to improve the lower limits on biomass boilers were used to prevent California brush fires how many or how much pollutants would be removed from our air? If we indeed [live on] one planet does it make sense to remove a small amount for a large sum of money when the same amount of money could make a large improvement in other parts of the nation or world?

Response: The emission limits and compliance options are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: The Boiler Rule -– and the identification of non-hazardous materials that are solid waste – the Waste Rule.

As proposed, these two rules threaten to eliminate the longstanding environmentally beneficial practice whereby furniture companies generate heat and process steam at their plants by combusting wood fuel generated from the furniture manufacturing process.

The proposed rules are of great concern to those of us who represent furniture manufacturers and the employees of those companies. Unless altered, the rules could actually have the perverse environmental affect of forcing the transition of furniture manufacturing facilities from the use of wood as a fuel to the combustion of fossil fuels while simultaneously forcing the disposal in the landfills of a clean, high BTU renewable fuel in the form of wood generated from the furniture manufacturing process.

At one facility located in North Carolina we currently estimate that in order to do fuel switching away from the combustion of wood fuel, we estimate an annual cost of $200,000 to dispose of this wood biomass. We also estimate that for that one facility an additional 12,000 tons of wood biomass fuel would be diverted to the landfill.

We also estimate that in order to do fuel switching and move away from wood biomass and switch to natural gas at that one facility with a small Fire tube boiler would cost $1.1 million to fuel switch and continue its operation today.

Response: The solid waste definition pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking.

Comment: There are unintended consequences of proposing emission standards that would require the installation of control devices that have not been demonstrated to achieve the proposed numeric emission limits and that would, in actuality, increase energy consumption and increase emissions.
There are unintended consequences of requiring the installation of pollution control devices that have not been demonstrated collectively to achieve the standards. For instance, the proposed CO limits for gas-fired units will require operating at much higher oxygen levels than typical, which will lead to increased fuel use and, as a result, increased CO_2 emissions. This is also true for oil-fired units. In fact, emissions of all pollutants other than CO will also increase because of the increased fuel use. Remarkably, the proposal does not indicated how the low CO levels will be achieved. Are we to take this as an indication that EPA's own analysis shows that it's unachievable? TO complicate matters, EPA has also included in this proposed rule precedent-setting energy assessment and ongoing energy management requirements that apply well beyond this source category which, we believe, will further highlight the inconsistency between the low CO levels and the optimum operation of boilers and process heaters.

Response: See the preamble for discussion on CO limits and technical conerns of control devices.

Comment: Imposing severe and unattainable emission limitations on sources that use or may use locally available alternative fuels such as bio-based fuels, landfill gas, and process off-gases, will decrease the use of alternative fuels and put greater demand on conventional fossil fuel use to the extent that continued operations are justified. These impacts are counter to the stated administration goals of improving national energy efficiency, reducing greenhouse gases, increasing national security, and increasing employment.

Response: See the preamble for discussion of achievability of emission limits, how we adjusted CO levels, and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Document Control Number: EPA-HQ-OAR-2002-0058-2207
Comment Excerpt Number: 1

Comment: People still burn their yards to kill insect pests and just last year the Federal government PAID us to burn thousands of acres of timberland to cut down on the fuel supply and decrease the risk of wild fire. We do some of this every year anyway, last year we just got paid for it.
Our boiler is used to burn sawdust that is generated by sawing lumber. The steam is then used to dry our lumber. The fuel is the same material (pine trees) that we were paid to burn last year. If this fuel was not burned we would have to pay someone to dispose of it and we would have to burn natural gas or fuel oil to dry our lumber.

Response: It is not our desire to preclude operators from burning biomass. The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Comment Excerpt Number: 2

Comment: If the ruling is written into law as proposed, the future of the U.S. biomass renewable energy market will be significantly impacted. Most new plants will not be feasible from a financial perspective given the high costs associated with the integration of needed technologies and equipment. There will be a significant increase in the cost to make power and Utilities will be forced to pass this onto the consumer. Resulting in a much higher price for electricity. Thus, it is believed that the proposed ruling will discourage, if not eliminate, new development of renewable biomass power. We believe that this is not the intent of the current Administration from an energy or economic policy perspective. As a form of renewable energy. biomass energy is CO, neutral hence does not contribute (0 the global green house gas emissions. Furthermore, producing energy form biomass clearly helps our rural economy and energy security.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 2

Comment: We do not have a boiler, but instead we dry our lumber with a direct fired natural gas kiln. As an engineer, I have had a long range plan of converting our drying system from natural gas (a fossil fuel) to a steam kiln with a biomass burning boiler (our own sawdust – a carbon neutral renewable resource). The plan included a co-generation system to produce electricity for our plant and possibly some of the community. We have cancelled all work on that project because of Boiler MACT. This was one of the plans for the future to make us more efficient and help our company survive in a competitive world. Now this won't happen, at least until these restrictive proposals are defeated. Even then, I don't know if I would ever recommend this, when some group at the EPA could shut down a system with few regulations that do not even have to be approved by Congress.

On the one hand, government wants us to use more biomass and at the same time creates regulations that make that impossible. I don't understand it.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Troy Runge
Commenter Affiliation: Wisconsin Bioenergy Initiative
Document Control Number: EPA-HQ-OAR-2002-0058-2353.1
Comment Excerpt Number: 2

Comment: The hydrogen chloride (HCl) limit will require many biomass fuel boilers to install scrubbers or inject an alkaline sorbent such as lime. The mercury (Hg) limit would require many boilers to install powdered-activated-carbon-sorbent injection systems, although sufficient data does not exist to know whether activated carbon injection is capable of reducing mercury emissions to the levels required by the new rule. The Carbon Monoxide (CO) and dioxin/furan limits will pose additional challenges for most biomass boiler projects as little emissions testing has been conducted to understand the magnitude of these emissions or how best to control them. Therefore, the stringent emission limits may force new biomass fuel boiler projects either to significantly upgrade their existing pollution-control equipment or consider switching to natural gas. Ultimately, this additional hurdle for the use of biomass will increase the use of fossil fuels, which is counterproductive to President Obama's energy policy and Wisconsin's investment in bionenergy.

We believe the proposed EPA Boiler MACT rule has the following negative unintended consequences:

The rule may severely limit and/or potentially eliminate the use of agricultural biomass fuels, threatening the development of a new local, renewable energy market.

The rule may increase either the facility costs and/or agricultural biomass fuel costs (e.g. fuel may have to be processed to remove minerals) so significantly that these homegrown fuels could not compete with imported fossil fuels like coal or natural gas.

Without agricultural biomass fuels, additional pressure would be put on wood resources (as a substitute for coal), potentially increasing the cost of woody fuels and distorting existing forest products markets, thereby threatening sustainability of harvesting.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 4

Comment: If owners or operators of combination boilers anticipate difficulty complying with the proposed CO standard, they may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. This unintended consequence of replacing biomass with coal is contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: John Williams
Commenter Affiliation: Maine Pulp and Paper Association
Document Control Number: EPA-HQ-OAR-2002-0058-1913.1
Comment Excerpt Number: 4

Comment: The limits being considered would necessitate combinations of emission controls that would have adverse effects on each other. For example, the conditions that affect the optimum emissions of CO may run contrary to minimizing emissions of NOx. Although NOx is not address in the Boiler MACT proposal, the northeastern states, including Maine, have focused on the control and reduction of NOx emissions to improve ozone. Another example is the use of activated carbon for mercury control. The presence of sulfur trioxide (SO3) can have a negative impact on carbon injection mercury removal. Small amounts of SO3 are generated during the combustion of sulfur-containing fuels. SO3 interferes with mercury removal by occupying active sites on the carbon.

Response: See the preamble for discussion on revised limits.

Commenter Name: Troy Runge
Commenter Affiliation: Wisconsin Bioenergy Initiative
Document Control Number: EPA-HQ-OAR-2002-0058-2353.1
Comment Excerpt Number: 6

Comment: The proposed MACT rule may disallow whole regions from developing new businesses in renewable biomass energy and encourage the continued use of coal fired boilers which have limits 10 times greater than biomass boilers.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Don Grimm
Commenter Affiliation: Hood Industries, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2352
Comment Excerpt Number: 14

Comment: In addition, biomass is a "clean" fuel in many of the same respects as the Gas 1 fuels. Perhaps more importantly, biomass-fired boilers produce no net GHG emissions, which make the combustion of biomass an important tool in managing and reducing the Nation's carbon footprint. Similarly, biomass is an abundant, renewable domestically-produced fuel that can help reduce reliance on foreign sources of fossil fuel and, thus, improve the Nation's energy security. Prescribing stringent HAP emissions limitations on biomass boilers will create a significant barrier to the continued use and expansion of biomass fuels and incentivize the use of less desirable fossil fuel alternatives.

In light of the inordinate costs of complying with the proposed HAP emissions limits for biomass boilers and the strong policy reasons for promoting the combustion of biomass, EPA has ample justification to prescribe work practices rather than HAP emissions limitations for biomass boilers.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Name: Kevin Bilbrey
Commenter Affiliation: Clarke County Pole and Piling Co, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2414.1
Comment Excerpt Number: 1

Comment: The proposed rules will have a detrimental effect on our company. Our company currently produces untreated wood poles and piling that are primarily utilized by wood preservation companies. After treatment, the wood poles are used primarily by electric utility companies for transmission and distribution of overhead lines to their customers. Treated wood piling is utilized by pile driving companies for foundation support as part of commercial, residential and municipal construction projects. We are currently installing a boiler that will burn wood biomass generated by our on-site pole and piling peeling operations. Steam generated from our boiler will be used a newly constructed on-site dry kiln to remove moisture from the wood poles and pilings prior to being sold to our customers.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass use.

Commenter Name: Raymond J. Nutting
Commenter Affiliation: County of El Dorado Air Quality Management District
Document Control Number: EPA-HQ-OAR-2002-0058-2713.1
Comment Excerpt Number: 1

Comment: The County of El Dorado has significant and highly productive agricultural and forested land integrated with urban and rural populations producing a wide range of biomass wastes. Although there is currently only one permitted biomass boiler operating in the county, the Board supports programs and plans for new facilities to convert biomass wastes into renewable energy in properly designed, operated, and controlled facilities. Such biomass utilization has shown to provide significant reductions in particulate matter, toxic pollutants, and greenhouse gases as compared with alternative disposal methods of open burning, land filling or in-field degradation.

The AQMD Board is very concerned with the potential consequences of the proposed regulations and does not support the new Maximum Achievable Control Technology (MACT) standards for industrial boilers for major sources and area sources. The proposed boiler MACT standards have not been properly determined and if implemented will result in multiple adverse outcomes. Compliance with this regulation will require existing facilities to install expensive and mostly untested "end of pipe" control technologies, which are not proven necessary to protect human health or environment. Such scenario will almost certainly cause significant increases in local and regional levels of particulate matter, toxic pollutants and greenhouse gases since unmanaged biomass wastes will be consumed by wildfires, through prescribed burning or be land filled. It will be necessary to burn more fossil fuel to accommodate for lost biomass energy.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: Advantages of utilizing biomass will diminish under the EPA proposed rules at the same time other departments of the government are encouraging and even subsidizing biomass facilities.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Joe O'Rourke
Commenter Affiliation: F.H. Stoltze Land and Lumber Co
Document Control Number: EPA-HQ-OAR-2002-0058-2418.1
Comment Excerpt Number: 1

Comment: These proposed rules will have a significant, detrimental impact on our company and on our employees.

We are a family-owned sawmill located in Columbia Falls, MT. We produce up to 70,000,000 boardfeet of lumber per year. We have been in business in the same location since 1923. We employ 117 people.

We have a bank of four boilers that are now 100 years old. Those boilers burn woody residues that are a byproduct of sawmill lumber production. We are currently examining replacing these old boilers with a newer boiler system that would also be capable of power generation. The cogeneration boiler would produce both process heat for our lumber drying operations, as well as generating electrical power that would be sold as renewal, carbon-neutral (green) energy to the power grid.

The EPA proposed rules referenced above would not only make our goal of generating a combination of process heat and green power from a renewable resource, much more difficult, it would threaten the very existence of our business and the jobs of our employees.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Jon Geenen
Commenter Affiliation: United Steelworkers

Comment Excerpt Number: 1

Comment: If the rules go into effect as written they will create a huge incentive to every industrial user of renewable biomass to switch to natural gas, contrary to the intent of Congress and contrary to the stated policy of the current administration.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Claude Audet
Commenter Affiliation: Boralex, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2387.1
Comment Excerpt Number: 2

Comment: Boralex contributes significantly to improving the environment by utilizing wood residues generated at saw mills, pulp mills and large bark piles that, in the past, posed substantial environmental threat to ground and surface water and posed risk of fire through spontaneous combustion. Trees targeted for harvesting are done so in a sustainable manner. The saw logs and pulp wood are removed for market with only the tree limbs and branches remaining. The branches and limbs are chipped, purchased by Boralex and used as a part of the biomass fuel source at its facilities. This biomass is waste wood it is NOT the trunk portion of the tree that has marketable opportunities. Combustion occurs under controlled conditions and emissions are reduced using control devices which, at a minimum, meet EPA's Best Available Control Technology (BACT) criteria. When the biomass is combusted under controlled conditions in our boiler furnaces, no additional CO_2 impacts occur.
Conversely, letting these wood residues decompose in the forest will cause greenhouse gases such as methane, a greenhouse gas that is 25 times more potent than CO_2 to be emitted directly into the air. It also takes time for the decomposition process to occur. During that time, the limbs and branches cover the forest floor, significantly slowing forest regeneration. Forest fires are also known to occur as a result of poor forest management practices. Forest fires often result in tremendous amounts of combustion by¬products being released uncontrollably into the atmosphere. Significant environmental, societal and economical impacts often result, such as wildlife habitat destruction and surface and ground water pollution, all of which can take many years to recover. The threat of loss of life from an uncontrolled forest fire is always present and, economic losses are often staggering.
Combustion of biomass for energy production makes sense. Biomass displaces fossil fuels (a significant climate change benefit) and moves our nation closer to energy independence, a goal that we should all share and do our utmost to obtain.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Jack Carter
Commenter Affiliation: Weyerhaeuser Company
Document Control Number: EPA-HQ-OAR-2002-0058-2797.1
Comment Excerpt Number: 2

Comment: We are concerned with how biomass is treated as a fuel category, which touches on the MACT floor/technical feasibility issues discussed above and on many of the issues noted in our Specific Comments section that follows. Because Weyerhaeuser is a major grower and provider of timber and manufacturer of wood and pulp/paper products, we have a significant interest both in the markets for the primary timber resources and secondary materials that end up as biofuels or biomass fuels. As on-site energy producers and consumers, most of our mills use significant quantities of biomass for fuel in its various forms and from a variety of sources. While some amount of fossil fuels are used at most mills and some smaller mills use only fossil fuels, most of our mills primarily use biomass to fuel their boilers and process heaters. In fact, using 2009 data as a snapshot, among our five U.S. pulp mills the median biomass-sourced fuel energy consumed for on-site energy production was 91% of the total on-site fuel energy consumed. For our major and area source wood products mills in the U.S. that utilize biomass fuels, the median biomass fuel energy was 85% of the total on-site fuel energy consumed. Btu basis, estimated from all biomass fuels used to fire on-site boilers and process heaters during 2009. For pulp mills this includes recovery furnaces combusting the biomass contained in the recycled pulping liquors. Our mills also marketed some 4800 billion BTUs in biomass residuals fuels energy to third parties in 2009. And although we do not have a specific estimate, we expect an even larger additional amount of biomass fuel is derived from our timber and forest residuals sales to third parties. Use of these renewable biomass fuels supports the Nation's goals to reduce dependence on foreign energy sources, reduce the greenhouse gas footprint of energy production, and to incent the long-term keeping of working forest lands as forest. The AWC and AF&PA comments go into more detail on the Forest Products Industry significant use of biomass to self-satisfy energy needs and the NAFO comments address the growing use and importance of this renewable resource nationwide. For example, the AWC and AF&PA comments identify that there are over 800 boilers and process heaters at wood products facilities in the U.S. and the majority of these boilers burn biomass.
Unfortunately, EPA creates a set of disincentives for biomass use because of how the proposed emission limits have been set and because of problems with EPA's use of the emissions data for several of the HAPs.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Jay Galloway
Commenter Affiliation: Tolleson Lumber Company
Document Control Number: EPA-HQ-OAR-2002-0058-2452.1

Comment Excerpt Number: 3

Comment: Ironically, the proposed rule will drive companies to switch from burning renewable biomass to burning nonrenewable fossil fuel (natural gas) – the very opposite to protecting the environment!

Response: EPA recognizes that the situation of each affected entity is different, and although some facilities may opt to switch to natural gas in lieu of biomass combustion, the data show that many biomass facilities are at or below the final emission limits. This suggests that many facilities will adopt biomass fuel specifications or install controls in order to meet the emission limits. Furthermore, EPA has determined that changes from the proposal have reduced economic impact on many biomass facilities; see the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Commenter Name: James P. Brooks
Commenter Affiliation: Maine Department of Environmental Protection, Bureau of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-2746.1
Comment Excerpt Number: 4

Comment: Reducing CO is likely to increase NOx, or will create the need for additional NOx control. This is contrary to other air quality efforts to address regional haze and interstate transport. Many Maine facilities have installed SNCR or low NOx burners to meet current NOx standards. The Maine DEP is concerned that the effort and expense necessary for many facilities to comply with the proposed standards will have little real impact on the pollutants of concern that EPA is directed to address in Section 112 of the Clean Air Act.

Response: See the preamble for discussion on CO limits.

Commenter Name: Arthur N. Marin
Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 4

Comment: NOx reduction strategies for ozone reduction may be negated if CO limits for HAPs are too low. For example, lime kilns have experienced exceptionally high NOx values (1100 ppm NOx) resulting from CO controls. [See submittal for graphical example of this tradeoff, which is a plot of annual NOx vs. CO emission rates (lb/mmBtu) obtained from stack tests at a paper mill waste fuel incinerator.]

Response: See the preamble for discussion on CO limits.

Commenter Name: Robert Ellerhorst
Commenter Affiliation: Michigan State University
Document Control Number: EPA-HQ-OAR-2002-0058-2816.1
Comment Excerpt Number: 4

Comment: Maximizing combustion efficiency must be balanced with the potential increase of nitrogen oxide (NO.) emissions that could occur when combustion efficiency is associated with high chamber temperatures. Maintaining reduced NO levels is of particular concern to MSU in order to comply with current air use permit limits for NO as well as Clean Air Interstate Rule (CAIR) ozone season requirements.

Response: See preamble for discussion on relationshipo between CO and NOx emissions.

Commenter Name: Kevin Bilbrey
Commenter Affiliation: Clarke County Pole and Piling Co, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2414.1
Comment Excerpt Number: 4

Comment: This is absurd given the fact that wood biomass is greenhouse-gas neutral and the government continues to encourage the increased use of biomass as a renewable energy. Wood biomass produces no net addition of CO_2 since the CO_2 emitted is equal to the CO_2 removed from the atmosphere in the creation of wood fiber.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Robert Klemans
Commenter Affiliation: Florida Electric Power Coordinating Group Environmental Committee
Document Control Number: EPA-HQ-OAR-2002-0058-2733.1
Comment Excerpt Number: 6

Comment: EPA HAP Regulation of Biomass. FCG believes that renewable fuels should be considered as part of a diverse energy supply portfolio, and our members are pursuing options, such as biomass, that can help us continue to provide reliable and affordable energy to our customers.

Economic renewable energy resources are unevenly distributed across the United States and the Southeast. Currently, one of Florida’s most promising economic renewable resources is biomass. Most renewable resources provide an intermittent supply of energy, but biomass generation is capable of producing a reliable supply of baseload energy, making it extremely beneficial.

However, the stringent limits and requirements in the proposed IB MACT decrease the prospect of producing reliable renewable energy from biomass. Florida needs the capability of producing renewable energy from biomass. FCG believes the proposed stringent emission limits within the proposed IB MACT may hinder the technologic and economic drivers for new and biomass conversion projects in Florida.

EPA should encourage the combustion of biomass as substitute fuel for coal or oil as a matter of good public policy. The combustion of biomass will become increasingly important to utilities if renewable energy standards are adopted by more states and are possibly applied to all states as a result of federal mandates. Biomass is an abundant and renewable domestically-produced fuel that can help reduce reliance on foreign sources of fossil fuel. Prescribing stringent HAP emissions limitations on biomass boilers will create a significant barrier to the continued use and expansion of biomass fuels.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Tim Keneally
Commenter Affiliation: KapStone Paper and Packaging Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-2673.1
Comment Excerpt Number: 9

Comment: EPA should understand that KapStone may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. This unintended consequence of replacing biomass with coal is contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.

Response: See the preamble for revised emission limits.

Comment: Section 112(h) Work Practices for Natural Gas-Fired Boilers Over 10 mmBtu/hr Are Appropriate as a Matter of Policy.

The application of work practices to natural gas-fired boilers/process heaters also is justified as a matter of public policy. As EPA notes in the preamble, requiring natural gas-fired boilers and process heaters to install costly add-on controls may create a disincentive for switching to natural gas. The proposed work practices approach for natural gas boilers/process heaters eliminates the disincentive that would be created by stringent emissions limits that penalize the low-HAP emissions of this fuel. As noted earlier in these comments and as demonstrated by EPA's database for this rulemaking, natural gas-fired boilers and process heaters have some of the lowest HAP emissions and therefore pose very low risk. Consequently, many auto facilities already have expended large amounts of capital switching to natural gas as a means to minimize regulatory concerns.

For example, a number of facilities have converted coal-fired boilers to burn natural gas (with some having fuel oil back-up and/or ability to burn landfill gas as well) over the last couple decades, which has helped areas comply with new, more stringent National Ambient Air Quality Standards (NAAQS). For those facilities that have not converted, stringent emission limits that necessitate costly add-on controls will serve to discourage further conversions to lower HAP fuels. Specifically, if both coal-fired boilers and natural gas-fired boilers are subject to stringent emission limits and require costly add-on controls for purposes of complying with the limits, coal will be more attractive given the historically low price of that fuel. Furthermore, add-on controls will decrease boiler efficiency and increase fuel consumption. These are "absurd results" that run contrary to EPA's efforts to encourage industry to increase energy efficiency and move to cleaner, lower-polluting fuels. These policy considerations further bolster EPA's decision to impose work practices on larger natural gas-fired boilers and process heaters.

Response: Natural gas boilers do not have emission limits but must follow work practice standards.

Comment: Wwe believe that EPA should take into consideration how this rule could affect the emissions of non-HAP pollutants and whether the rule produces the greatest overall air quality and public health improvement. For example, the proposed Boiler MACT requirements for carbon monoxide (CO) may cause increases in greenhouse gas and nitrogen oxide (NOx) emissions. The EPA's current approach to regulating air emissions does not prioritize pollutants for comprehensive air quality management and in some cases may exacerbate air quality issues.

Response: See the preamble for response regarding CO emission limits and their impacts on other pollutants.

Comment Excerpt Number: 26

Comment: To meet the proposed Boiler MACT limits may require controls in some circumstances, such as wet scrubbers, that will come into conflict with the effluent guidelines for wood products mills that prohibit discharge of process wastewaters. Certain air pollution control devices that generate process wastewater have previously been exempted from this effluent guideline when used at facilities also covered by the Plywood and Composite Wood Products (PCWP) MACT Rule (subpart DDDD). 40 CFR Part 429, the Timber Products Processing Point Source Category states that "there shall be no discharge of process wastewater pollutants into navigable waters" for facilities covered under subparts B, C, D and M (dry process hardboard, veneer, finishing, particleboard, sawmills and planing mills). In conjunction with the PCWP rule, these subparts were narrowly modified to allow discharge from air pollution control devices (APCD) associated with controlling HAP emissions covered by PCWP. However, mills in the wood products industry subject to Part 429 cannot legally discharge wet scrubber or other wet control device blowdown that are installed to comply with the Boiler MACT because they constitute process wastewaters. Scrubbers and wet electrostatic precipitators may be required by some wood product industry boilers subject to Part 429 in order to comply with these air standards. If EPA chooses to insist on compliance with numerical emissions limits in this situation, then the effluent guidelines definition of "process wastewater" in 40 CFR §429.11(c) must be amended to exclude wastewater from air pollution control devices on boilers and process heaters complying with the major source or the area source NESHAP. We refer EPA to the AWC comments on this issue, which provide more detailed descriptions of the APCD wastewater volumes and other relevant information to support a similar recommendation.

Comment: When faced with a decision to comply with the proposed rule for Gas 2 units, sources will have one of three basic options: (1) install the high cost controls EPA describes on page 32025 of the
proposed rule that would be needed for Gas 1 units – fabric filter, a wet scrubber, and an oxidation catalyst system, (2) flare (or install a thermal oxidizer) the process gas (and burn additional natural gas to make up for the lost heating value, and (3) install a new boiler just for the process gas. Any of these three options will be very costly. When faced with the difficulties of retrofitting existing boilers with air pollution control systems never envisioned (i.e. no space or structure available) or the expense and permitting difficulties of installing a new unit (not to mention the challenges of finding equipment that would meet the proposed new unit emission standards), we believe many facilities would opt for the flaring option.

At one of Eastman's facilities, we have estimated increased natural gas costs of $5M per year to replace lost heating value from just one process gas system that currently is burned in six existing gas-fired boilers. At one of our facilities, we operate three ethylene plants, each of which is highly integrated and burns its own process gas (primarily hydrogen and methane – no HAPs) for energy recovery in the ethylene plants' cracking furnaces and waste heat boilers. Natural gas is supplied to provide additional fuel as needed for these combustion units. While the cracking furnaces would be exempted from the Boiler and Process Heater MACT per proposed §63.7491(f) , the six waste heat boilers would be subject to the Gas 2 subcategorical standards. While we have no stack test or CEMS data on these units to judge their performance, we doubt these units could comply with the proposed CO standard. Due to anticipated prohibitive costs to install air pollution control devices such as fabric filters and oxidation catalyst systems, Eastman would likely decide to flare this process gas and replace it with natural gas at an estimated annual cost of $3.5 M. The increased VOC emissions from flares (less efficient than boilers) and the increased NOx emissions from the flaring, while legal, would be an unfortunate outcome of compliance with the proposed rule.

Response: See the preamble for discussion of achievability of emission limits, how we adjusted CO levels, and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: The proposed unachievable emission limits applicable to landfill gas units are in direct conflict with programs EPA has put in place to promote the advantageous use of this fuel. EPA established the Landfill Methane Outreach Program (LMOP) in 1994, which, according to EPA's website, is a voluntary assistance and partnership program that encourages the use of landfill gas as a renewable, green energy source. [Footnote: See http://www.epa.gov/lmop/basic-info/index.html (emphasis added).] EPA's website explains that the agency "launched LMOP to encourage productive use of [landfill gas] as part of the United States' commitment to reduce GHG emissions under the United Nations Framework Convention on Climate Change."

[Footnote: See http://www.epa.gov/lmop/basic-info/index.html (emphasis added).] By preventing emissions of methane through the development of landfill gas energy projects, LMOP strives to assist businesses, states, energy providers, and communities in protecting the environment and building a sustainable future. [Footnote: See http://www.epa.gov/lmop/basic-info/index.html (emphasis added).] EPA notes on its website that there are 519 operational landfill gas energy projects in the U.S. EPA also estimates that approximately 530 other landfills are good candidates for projects to turn their gas into energy. [Footnote: See http://www.epa.gov/lmop/basic-info/index.html (emphasis added).]

As EPA describes on its website, landfill gas is extracted from municipal solid waste landfills and then collected where it is processed and treated for further use. [Footnote: See http://www.epa.gov/lmop/basic-info/index.html (emphasis added).] Depending on the design, up to 60-90% of the methane emitted from a landfill is captured by a landfill gas energy project thereby significantly reducing a potent GHG. [Footnote: EPA explains on its website that "methane is a very potent greenhouse gas that is a key contributor to global climate change (over 21 times stronger than CO_2). Methane also has a short (10-year) atmospheric life. Because methane is both potent and short-lived, reducing methane emissions from MSW landfills is one of the best ways to achieve a near-term beneficial impact in mitigating global climate change." Id.] According to EPA's website and recent presentation materials from EPA, landfill gas can be used to generate electricity and is currently powering close to 1 million homes (supplying 13 billion kilowatt-hours). Landfill gas also can replace fossil fuels in industrial and manufacturing operations or can be upgraded to pipeline-quality gas where the gas may be used directly or processed into an alternative vehicle fuel. [Footnote: See http://www.kdheks.gov/waste/workshops/works10/presentations/hamburg-EPALMOPsuccessstories-2010.pdf] In fact, according to the DTE Biomass Energy's website, landfill gas is processed to a degree that it is of natural gas quality and can be injected directly into the natural gas pipeline distribution system for use by consumers. [Footnote: See http://www.dtebe.com/services/pipelineGas.html.]

In light of the importance of encouraging the use of landfill gas as a renewable green energy fuel as evidenced by EPA's LMOP efforts and projects, the Auto Group urges EPA to impose work practice standards on landfill gas boilers/process heaters at major sources instead of emission limits. As explained above, landfill gas is an important energy resource and EPA should promote the continued use of this fuel rather than prevent boilers/process heaters from combusting landfill gas because these units are incapable of meeting the proposed emission limits (or some other emission limit that EPA believes represents the average of the best performing 12%). Furthermore, the use of landfill gas reduces the GHG load and offsets the use of other fossil fuels, which are higher in HAP emissions and are non-renewable. Penalizing major sources using landfill gas-fired boilers/process heaters by imposing an unachievable emission limit does not make sense from a policy perspective.

If finalized as proposed, the emission limits applicable to landfill gas units will have the result of severely restricting the future use of landfill gas and could, in all likelihood, lead to this beneficial fuel being once again flared or routed to other devices that may not be as efficient in combusting landfill gas or as effective in reducing other potential emissions (e.g., GHGs) as the boilers/process heaters currently being used. It is important to utilize the energy that landfill gas can provide and reduce the GHG load associated with the use and dependence on other fossil fuels. For these reasons, EPA should impose work practice standards on landfill gas units similar to what is being proposed for natural gas and refinery gas units.

Response: See the preamble for new subcategory definitions and discussion of CO limits.

Comment Excerpt Number: 171

Comment: Large integrated chemical plant sites strive to be as energy efficient as possible. One way to promote energy efficiency is to capture off-gas from petrochemical and chemical plant off-gas streams and re-use these streams as fuel in a variety of combustion sources. Plant sites are designed to use many types of “gas 2” streams as a fuel in order to have energy efficient operations. If gas 2 fuels are subjected to stringent emission limits instead of work practice requirements, the rule likely will force facilities to dispose of process off-gases in other types of combustion sources including flares, which results in more natural gas being used, inefficient operations, and an increase in greenhouse gas emissions.

Response: See the preamble for discussion of achievability of emission limits, how we adjusted CO levels, and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: Most boilers are designed to mix fuel and air at an appropriate ratio, and to provide sufficient residence time for the fuel to combust completely. Obviously, these factors are fuel-dependent, as a gaseous fuel will require less time for complete combustion than a liquid fuel, which in turn requires less time to burn than a solid fuel. The need for longer residence time is why the radiant sections in solid-fuel fired boilers are larger than for gas-fired units. The size of the boiler is typically optimized to allow for complete combustion, while minimizing the cost of construction materials. If the construction cost were not a concern, a new boiler could be designed with additional residence time to complete the combustion process and minimize CO emissions.
Unfortunately, increasing the size of the furnace is not an option for existing units. For these units, the strategy for reducing CO emissions is typically to raise the level of excess oxygen. The increase in oxygen concentration has two positive effects. First, it acts to overcome poor distribution of the fuel. Second, it increases the flame temperature, which speeds up the combustion reactions, allowing more complete combustion to occur for the same residence time.

However, there are also a number of negative impacts associated with operating a boiler at higher levels of excess oxygen. The residence time of combustion gases in the furnace decreases, resulting in less time for complete burnout of intermediates such as CO. Many boilers do not have sufficient fan capacity to run with elevated excess oxygen at the high end of the load range. Therefore, these units would effectively be derated by such a strategy. A site might have to add another boiler to offset the reduction in steam generating capacity. If the excess oxygen is increased to very high levels, CO and hydrocarbon emissions will increase and flame stability is impaired, mainly because this leads to a cooler flame.

The minimization of excess oxygen in boiler applications is a key feature for maximizing boiler efficiency. For a given fuel, the boiler efficiency is defined by the amount of combustion air that is used, and the difference between the ambient temperature and the stack exhaust temperature. The more air that is heated up through the combustion process, the more heat is lost to the atmosphere, causing the boiler to be less efficient. A less efficient boiler will require more fuel to be fired to produce a given amount of steam. The additional fuel firing results in higher operating costs, and higher greenhouse gas emissions.

Minimizing the level of excess oxygen is also a primary strategy for reducing NOx emissions from a boiler. The NOx formation mechanisms are dependent upon the temperatures in the flame zone, and the stoichiometry of the fuel and oxygen introduced into the furnace. Reducing the level of excess oxygen reduces the peak flame temperature, which reduces the rate at which the nitrogen in the air dissociates. As such, there is less monatomic nitrogen available to be oxidized to form ‘thermal NOx’. Similarly, if there is less oxygen present, the monatomic nitrogen is less likely to be oxidized (and more likely to react with a second monatomic nitrogen to form diatomic nitrogen). This reduces both the amount of thermal NOx, and the ‘fuel NOx’ (NOx that is formed by the release of fuel-bound nitrogen). Therefore, increasing the level of excess oxygen will result in higher NOx emissions.

Comment: The effluent limitations guidelines for the Timber Products Processing Point Source Category in 40 CFR part 429 subparts B (Veneer subcategory), C (Plywood subcategory), D (Dry Process Hardboard subcategory), and M (Particleboard Manufacturing subcategory) prohibit the discharge of process wastewater pollutants. “Process wastewater” is defined quite broadly, with only a few exclusions. See 40 C.F.R. § 429.11(c). Facilities within these source categories would be prohibited from discharging the blowdown from a wet scrubber installed on a boiler or CISWI unit. Additionally, numerous other types of facilities that manufacture structural and engineered wood panels that are not covered by the cited effluent guidelines (such as medium density fiberboard) have NPDES permits that prohibit the discharge of process wastewater pollutants, based on a Best Professional Judgment determination that extrapolates from the effluent guidelines.

For these types of facilities, installing any scrubber or a wet electrostatic precipitator to meet new HCl or PM limits may not be practicable. Many mills subject to a zero-discharge requirement already must go to great lengths to manage the wastewater they already generate, and they would be unable to accommodate any additional generation of substantial amounts of wastewater. Many of these facilities are in rural areas where public sewer systems are unavailable, and if they cannot discharge their wastewater pursuant to an NPDES permit they have no feasible means for disposing of it. (In some cases, it might be theoretically possible to truck the wastewater to a commercial wastewater treatment facility or publicly owned treatment plant, but the cost would be prohibitive.)

Response: See the response to comment EPA-HQ-OAR-2002-0058-2797.1, excerpt 26.

Comment: While we believe that a work practice standard would be the best way to deal with the range of circumstances that might be presented at wood products facilities, if EPA insists on settling numerical limits on HCl and other pollutants that could require the installation of wet air pollution control devices, EPA should further modify the definition of "process wastewater" in 40 C.F.R. § 429.11(c) to exclude "wastewater from air pollution control devices on boilers and process heaters … for Industrial, Commercial, and Institutional Boilers and Process Heaters at major source facilities (40 CFR 63 Subpart DDDDD) and for Industrial, Commercial, and Institutional Boilers at area sources (40 CFR 63 Subpart JJJJJJ)." As is currently done for wastewater from air pollution control devices installed to meet the Plywood and Composite Wood Products NESHAPs, the excluded wastewaters would be subject to effluent limitations developed by the permit writer on a Best Professional Judgment basis. See 69 Fed. Reg. at 45,965.

Commenter Name: Ronald W. Gore
Commenter Affiliation: Alabama Department of Environmental Management
Document Control Number: EPA-HQ-OAR-2002-0058-2465.1
Comment Excerpt Number: 1

Comment: The proposed rules impose severe emission restrictions on the combustion of biomass. Since many facilities may not be able to afford the controls required to meet the proposed MACT limitations, it appears that the proposed rules will drive these facilities towards the combustion of natural gas to meet energy requirements. Since biomass is a renewable source of energy, this appears to run contrary to the current Administration's stated desire to move away from fossil fuels and towards renewable sources of energy.

Alabama, along with other States, is facing mandatory renewable energy targets in the future. For obvious reasons, wind, solar, geothermal, and many other renewable sources are not viable in Alabama. Biomass appears to be the primary alternative. Our State may not be able to meet its goals if biomass usage is discouraged.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Ronald W. Gore
Commenter Affiliation: Alabama Department of Environmental Management
Document Control Number: EPA-HQ-OAR-2002-0058-2465.1
Comment Excerpt Number: 2

Comment: Given the current Administration's desire to regulate Greenhouse Gas emissions, it is perplexing to the Department that the EPA would drive facilities away from utilizing what may be considered a 'carbon neutral' fuel. Furthermore, when combined with the recently proposed solid waste definition, it appears that the fate of wood residuals may be landfills, where it will decay into methane, which has a CO_2 equivalence of 25:1.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits. Also, the solid waste definition pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking.

Document Control Number: EPA-HQ-OAR-2002-0058-2736.1
Comment Excerpt Number: 3

Comment: The proposed regulation creates, what would be assumed as, unintended consequences for using Landfill Gas as a fuel source, where stringent emissions limits will be applicable, stack testing will be required, CEMS / COMS installation and operating requirements may be applicable, and additional record keeping requirements, as well as the additional costs of compliance will be realized. The proposed regulation would drive up the cost for continued development of Landfill gas as a fuel source, force the site to revert back to Natural Gas, and future landfill gas utilization projects would be abandoned. As proposed, this regulation presents a negative connotation from EPA that Landfill Gas, used as a source of fuel, has no benefit to the environment and should receive no regulatory amnesty similar to natural gas or refinery gas.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: Biomass power has long served as an important and reliable alternative source of electricity. It is a pillar of long-standing renewable portfolio standards adopted in many states, especially in California. Looking forward, biomass is included as one of the renewable technologies eligible for the Renewable Energy Standards proposed in several bills before this Congress. Indeed, according to the Congressional Research Service, biomass power represents over half of the total renewable energy generation in the United States.

Biomass power plants nationwide divert millions of tons of material that otherwise would have been disposed of through more polluting methods such as landfilling or open burning. The use of woody biomass and agricultural residues as fuel in biomass boilers dramatically reduces the emissions of particulate matter, carbon monoxide, and nitrogen oxides that would be byproducts of open burning. In addition, biomass material derived from forest management activities provides further emissions benefits by reducing the risk of wildfire and improving forest health. More specifically, the Colmac plant on the Tribe's reservation diverts over 1,000 tons per day of wood wastes that would otherwise be deposited in landfills to biodegrade, burned in the open fields, or. left on the forest floor to rot or eventually burn in either a prescribed burn or in a wildfire.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 7

Comment: If implemented as proposed, the MACT regulations will have a significant impact on the ability of biomass-to-energy facilities to continue to operate in the State and the State's ability to meet its 33 percent renewable energy goals by 2020.

Development of biomass as an energy source is very important to the State of California. The State, through Governor Schwarzenegger's Executive Order S-06-06, establishes a 20 percent target for biomass within its established State goals for renewable generation for 2010 and 2020. Currently, generation from biopower resources provides about 20 percent of California's renewable energy or an estimated 2.8 percent of California's total in-state power generation.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Arnold Schwarzenegger
Commenter Affiliation: Governor Arnold Schwarzenegger

Comment: It is noted that lowering CO increases nitrogen oxides (NOx) emissions, i.e., the lower the CO limit is set, the higher the NOx emissions will be. This will be contrary to federal, state, and local programs aimed at reducing ground-level ozone concentrations by reducing NOx emissions.

Response: See the preamble for discussion on CO limits.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 54

Comment: Finally, it is very poor public policy to discourage the beneficial use of process and other off-gasses and, thereby, increase the demand for and use of fossil fuels. In fact, it reverses EPA‘s previous efforts to encourage such use. For example, EPA has been encouraging beneficial reuse of landfill gas for the last decade and of process vents since at least the early 1990s [Footnote: Since the early 1990‘s the Part 60 and 63 regulations have encouraged combusting regulated vent streams as fuel, by waiving performance tests and monitoring where the vent is combusted as or with primary fuel.] For some facilities, it will be much more economical and incur much less compliance liability to incinerate Gas 2 streams, rather than send them to fuel uses. The energy needed to replace the lost heat capacity and the additional energy needed to incinerate the Gas 2 streams will come from additional fossil fuel production and use. This will result in a net increase in national emissions, waste natural resources and increase imports of fossil fuels.

Recommendation: Combine the two proposed Gas 1 and Gas 2 subcategories and apply only a revised tune-up requirement as discussed further in Comment Section V.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: It is also important that the Agency fully evaluate the negative environmental impacts of forcing sources to install the full suite of controls needed here. The two primary environmental issues are the increased energy use required and the generation of additional emissions resulting from the control. Because oxidation catalyst requires a higher stack temperature than is optimal for a boiler or process heater some thermal efficiency will be sacrificed on each unit that has to install this technology. To achieve this will increase firing rates. Additionally, the controls themselves use electricity and generate solid and/or liquid wastes, the disposal of which requires energy (as well as cost and burdens). Because stack temperatures are not quickly quenched if oxidation catalyst is in place, dioxin/furan emissions are directionally increased. Furthermore, oxidation catalyst oxidizes SO2 to SO3, resulting in increased emissions of particulate (as sulfuric acid aerosol). The activated carbon systems needed for Hg and dioxin/furan control generate carbon particulate.

Recommendation: The Agency should include in its evaluation of the controls required for complying with this proposal the increased energy use and additional emissions that result from the controls.

Response: See the preamble for discussion on control device interactions.

Comment: Theoretically, complete combustion will occur when the exact amount of oxygen necessary to chemically convert all of the fuel to combustion products is present. For pure hydrocarbon fuels (containing only C and H), the combustion products are carbon dioxide (CO_2) and water (H_2O). If less than the theoretical amount of oxygen is added, there is insufficient oxygen to convert all of the CO to CO_2. As less oxygen is added, CO increases and CO_2 decreases. If more than the theoretical amount of oxygen is added, CO remains zero and the excess oxygen simply mixes with and dilutes the combustion products. Because the excess oxygen (and nitrogen, if the oxidant is air) absorbs heat that is lost in the stack gases and hence lowers thermal efficiency, the optimum theoretical operating point for maximum thermal efficiency is with exactly 100% of the theoretical air required for complete combustion (i.e., zero excess O2).

Practical Relationship Between Excess O2, CO, Efficiency and Safe Operation

Thermal efficiency in boilers and process heaters is typically defined in terms the percentage of chemical energy in the fuel converted to heat and transferred to the working fluid (steam, process feed, etc.). The majority of lost heat normally consists of latent heat in the stack gases and uncondensed water vapor. CO and unburned carbon (hydrocarbons, soot, char, etc.) are combustible, and as such represent lost thermal energy. Under normal combustion conditions with low combustibles, the thermal energy loss is usually insignificant compared to other losses (except perhaps with solid fuel-fired units where unburned carbon can be significant). Only when combustibles rises to very high levels for CO, thousands of ppm do they begin to contribute significantly to efficiency loss. Elevated CO also indicates atmospheres that are corrosive to metals at high temperatures and hazardous to personnel if exposed, so there are reasons besides efficiency loss to maintain low CO.

In practical systems, complete combustion is generally not achieved when the theoretical amount of oxygen is added because of imperfections in fuel-air mixing and other factors. Because of this, boilers and process heaters operate with a certain amount of excess O2. CO typically begins to rise steeply as excess oxygen is reduced and approaches zero (Figure 2, left). In oil-fired systems, smoke (soot) concentration also rises, typically before CO appears. The point of maximum thermal efficiency is typically within 1 or 2 percent above zero percent excess O2, defined by the tradeoff between increasing heat losses due to heat absorbed by dry gases as excess O2 increases and increasing CO as it decreases. The exact point at which the optimum is reached depends on the furnace, burner design and other factors unique to individual units.

While it would maximize thermal efficiency to operate at the point of maximum efficiency, variations in air and/or fuel flow, especially during load swings, can potentially reduce excess O2 below the optimum, raising CO emissions. Operating with too little oxygen can extinguish the flame creating potentially explosive conditions in the combustion chamber, or trip the flame safety system (if so equipped) shutting down the unit. Due to mixing imperfections in practical systems, elevated CO also can lead to regions of the furnace gas that are deficient in oxygen, which leads to accelerated high temperature metal corrosion that can decrease the life of tubes, tube hangers, and other components and cause tube leaks and/or structural damage. These conditions are impractical and potentially dangerous. Therefore, it is a best practice to define the minimum excess O2 that can be reached while maintaining CO and smoke below moderate levels during tuning, then raise the excess O2 operating level above this point to provide a margin of safety. Guidelines for tuning industrial boilers typically give a modest CO level (e.g., 100 to 400 ppm) or, for oil-fired units, a Bacharach smoke spot number “SSN” or “BSN” - (e.g., SSN of 2 for distillate oil and SSN of 4 for residual oil) as the maximum levels commensurate with minimum excess O2. These limits are typically reached at excess O2 levels between 0.5% and 3.0% for gas-fired units and from 2.0% to 4.0% for oil-fired units. There are a number of references on boiler and process heater tuning that describes this general process of combustion tuning for optimum efficiency and low emissions. [Footnote: EPA, 1983. Combustion Efficiency Optimization Manual for Operators of Oil- and Gas-Fired Boilers. EPA-340/1-83-023, Stationary

Source Compliance Division, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Washington, D.C.; Baukal, C.E. and Schwartz, R.E. The John Zink Combustion Handbook, CRC Press, Danvers, MA, 2001.]

Elevated CO emissions also can occur when excess O2 is too high (Figure 2, right). Flames are stabilized by recirculation of heat and radical species present at high temperatures from the flame back to the burner. At very high excess O2 levels, fuel concentrations and flame temperatures are low, reducing flame stability. Air velocity at the burner may exceed the flame speed, resulting in ignition instability and flame blow-off. It is very unsafe to operate in this region because potentially explosive fuel mixtures may be created in the combustion chamber that can cause severe mechanical damage and personnel hazard if the mixture in the furnace suddenly reignites from contact with hot surfaces. Most boilers and process heaters cannot reach this point at full load because of air supply limitations. However, this may occur in some systems at reduced load such as during normal turndown operations or during startup and shutdown.

Adverse Impacts of Minimizing CO

The discussion above emphasizes the optimization of excess O2, CO, smoke, efficiency and combustion stability to achieve maximum thermal efficiency commensurate with low emissions, safe operability and maintainability.

Response: See the preamble for discussion on CO limits.

Comment Excerpt Number: 123

Comment: EPA has proposed or solicited comment on CO limits of 1 ppm for Gas 2 units and 2 ppm for Gas 1 metal furnaces. It may be possible in some systems to achieve these levels under certain operating conditions, typically near full load where combustion chamber temperatures are highest and at higher excess O2 levels. However, this is not universally true because combustion chamber temperatures, residence times and mixing characteristics influencing CO burnout vary among different designs, depending on the unit design duty and other factors. Operating with excess O2 greater than the optimum operating range to achieve minimum CO results in a significant thermal efficiency penalty and/or unacceptable proximity to safety boundaries of the operating envelope (Relationship Figure below, right). In addition to thermal efficiency, lower flame temperatures associated with higher excess O2 typically result in additional heat input to the furnace to maintain sufficient radiative heat transfer for the process (radiative heat transfer is proportional to temperature to the fourth power, and so is very sensitive to changes in flame temperature). Also, it may not be possible to achieve a specific low CO level at full load due to combustion air supply constraints. The consequence may be an effective de-rating of unit capacity to achieve that condition. Thus, minimizing CO rather than optimizing all key parameters generally could be expected to increase energy consumption and may constrain production.

Response: See the preamble for discussion on CO limits.

Comment: Most boilers are designed to mix fuel and air at an appropriate ratio, and to provide sufficient residence time for the fuel to combust completely. Obviously, these factors are fuel-dependent, as a gaseous fuel will require less time for complete combustion than a liquid fuel, which in turn requires less time to burn than a solid fuel. The need for longer residence time is why the radiant sections in solid-fuel fired boilers are larger than for gas-fired units. The size of the boiler is typically optimized to allow for complete combustion, while minimizing the cost of construction materials.

Unfortunately, increasing the size of the radiant section is not an option for existing units. For these units, the strategy for lowering CO emissions is typically to raise the level of excess oxygen. The increase in oxygen concentration at a given unit load has two positive effects. First, raising the air flow rate increases air velocity at the burner, which may act to increase the rate of fuel-air mixing and decrease oxygen-deficient zones that provide pathways for escape of CO. Second, it tends to decrease the peak flame temperatures, reducing radiant heat transfer and raising furnace exit gas temperature, which speeds up CO oxidation reactions in the later stages of combustion, allowing more complete CO to occur. Offsetting these positive effects, increasing the air flow rate decreases bulk gas residence time in the furnace, reducing the time available for the relatively slow CO oxidation reactions to occur. To offset the decrease in radiative heat transfer, the fuel flow may need to be increased to meet process demand.

However, there are a number of negative impacts associated with operating a boiler or process heater at higher levels of excess oxygen. Many forced air and induced draft units do not have sufficient fan capacity to run with elevated excess oxygen at the high end of the load range. Therefore, these units would effectively be derated by such strategy.

The minimization of excess oxygen in boiler and process heater applications is a key feature for maximizing efficiency. The efficiency is defined by the amount of combustion air that is present, and the difference between the ambient temperature and the stack exhaust temperature. The more air that is heated up through the combustion process, the more heat is lost to the atmosphere, causing the unit to be less efficient. A less efficient unit will require more fuel to be fired to produce a given amount of steam. The additional fuel firing results in higher operating costs, and higher greenhouse gas and other emissions.

Minimizing the level of excess oxygen is also a primary strategy for reducing NOx emissions from a boiler or process heater. The NOx formation mechanisms are dependent upon the temperatures in the flame zone, and the stoichiometry. Reducing the level of excess oxygen increases peak flame temperatures but decreases oxygen availability, the net effect of which reduces the rate of thermal NOx formation. If there is less oxygen present, the monatomic nitrogen is less likely to be oxidized (and more likely to react with a second monatomic nitrogen to form diatomic nitrogen). Reducing excess oxygen typically reduces formation of both thermal NOx, and the ?fuel NOx‘ (NOx that is formed by the release of fuel-bound nitrogen). Therefore, increasing the level of excess oxygen typically results in higher NOx emissions.

Comment: C. Recently PSD "Tailoring Rule" Must be Addressed.
Facilities will have to install extensive emission control equipment to meet the proposed Boiler MACT emission limits. Specifically, EPA stated in the preamble that emission control would likely require a fabric filter (FF) plus carbon injection plus wet scrubber control plus combustion improvements or carbon monoxide (CO) catalyst. The installation of this equipment could result in increases in emissions of CO2e or criteria pollutants. The following are examples:

In general the installation of additional emission control equipment will increase the pressure drop that a boiler’s induced draft (ID) fan will have to overcome. If the ID fan is not upgraded the boiler steaming capacity will decrease because the previous air–to-fuel ratio cannot be achieved resulting in the requirement to increase the firing rate of the other facility boilers. Combustion of additional fuel in the other on-site boilers may result in a significant emissions increase triggering PSD.

Operation of additional emissions control equipment will require more electricity. A facility’s unused electrical generating capacity would be required to meet this demand thereby requiring additional fuel combustion to generate the steam required for the steam turbine. Additional fuel burning may result in a significant emissions increase triggering PSD.

Facilities may be required to make operational changes in order to meet the Boiler MACT limits that could result in increases in emissions of CO2e or criteria pollutants. The following are examples:

Fuel switching for multi-fuel boilers may be required to meet the proposed boiler MACT emission limits. A specific example is multi-fuel (e.g. wood and some coal) boiler that has over-fired air and it must combust additional coal in order to decrease the emissions of CO. This change in firing ratio of fuels may result in a significant increase triggering PSD.

A biomass boiler may have to increase its operating target for excess oxygen level in order to decrease emissions of CO in order to meet the proposed boiler MACT emission limit. The result is that the flue gas flowrate increases to a level that is beyond the capability that existing fabric filter can handle reliably and the amount of fuel that can be burned in this boiler is now administratively limited to match the capability of the fabric filter. This requires that the facility operate the backup natural gas package boilers which have no heat recovery system (e.g. economizer or air heater) to make-up the difference rather than invest in a larger fabric filter needed to meet the proposed Boiler MACT limits.

These are but a few general examples, where there are many more to show how the PSD tailoring rule could be triggered due to changes facilities must make to achieve compliance with the proposed Boiler MACT rule.

Response: See the preamble for revised emission limits.

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 254

Comment: Refinery heaters and vertical cylindrical heaters in general have much lower space heat release rates than package boilers. This is good and bad for CO destruction. For safety these heaters have a lower space heat release rate to prevent over heating of oil or other product in the tubes to prevent coking or fires. The lower space heat release rate (~20,000 Btu/cubic foot) is good for CO destruction. The large heater size causes other CO issues due to down draft of low temperature products of combustion along the heater walls. These low temperature products mix with the outside of the flame and quench CO (below 1,500 deg F) and cause a slight increase in CO.

* Reducing CO to extremely low levels may require that these boilers be de-rated in capacity to allow complete CO burnout.
* • To meet Low NOx and Low CO without back end catalysts will require existing package boilers to be significantly de-rated, by as much as 50%, and new boilers to be designed with furnaces approximately twice as big.
* To require very low CO in process heaters may require re-design of the burners with possible refractory walls to prevent quenching or back-end catalysts.

Response: See the preamble for discussion on CO limits.

Commenter Name: Matthew Todd and David Friedman

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 255

Comment: Allowing reasonable CO levels also provides acceptable operation at lower loads when fuel-air ratio control is not as accurate. For both boilers and process heaters, at low loads, the temperatures in the furnace are significantly reduced and higher excess air is required. This is especially important in multi-burner boiler installations where NFPA does not allow air flow reduction below 25%. The mixing energy of the flame is also much lower and therefore CO always will increase at lower firing rates.

* Reducing CO to extremely low levels may significantly limit the operational turndown of many boilers and process heaters.
* Reducing CO to extremely low levels, and having no exception for operation during SSM periods, may limit the life of the units due to a need to increase the rate at which the unit is warmed up to minimize operation at lower loads.

Response: See the preamble for discussion on CO limits.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 256

Comment: Allowing reasonable CO levels also provides an achievable operating window for load following boilers. Typical metered control systems allow air to lead fuel on increasing load and fuel to lead air on decreasing load. This results in fuel lean operation during transient load conditions.

* Having to maintain tight CO limits may require that the speed of burner load changes be limited to prevent high excess air conditions that generate high CO. This may inhibit a boilers ability to respond as quickly as needed to changes in steam demand.

Response: See the preamble for discussion on CO limits.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 274

Comment: The addition of large fans, pumps, compressors, feeders and stack gas reheat coils translates directly into a significant increase in energy consumption compared to that for the unit prior to retrofit. Stack gas reheat alone would account for ~1.2% of fuel heat input assuming a required temperature rise from 145 0F to 200 0F. Some but not all of this increase may be recovered by tuning and by the additional heat recovery. It is unlikely that the increase could be offset by marginal thermal efficiency improvements that could be achieved by boiler tuning (~1%) or heat recovery associated with gas cooling between the oxidation catalyst and fabric filter (~0.5%).

The incremental energy consumption associated with add-on controls translates directly to incremental increases in emissions of not only HAPs but also carbon dioxide (CO_2, a greenhouse gas), NOX, SO2 and PM. Incremental energy consumption due to stack gas reheat, electric fans and pump drives (adjusted for fuel-to-electricity conversion heat rate) equates to several percent of fuel heat input. Increases in pollutant emissions will be approximately proportional to the energy increase. Increased HAP production due to energy consumption will at least partially offset HAP reductions achieved by add-on controls. An increase in other pollutants would be unwelcome at a time of sharply increasing pressure to decrease those emissions in light of emerging greenhouse gas rules, PM2.5 implementation and tightening of ozone, NO2 and SO2 ambient standards.

Commenter Name: Michael J. Burns
Commenter Affiliation: Ever-Green Energy, LLC
Document Control Number: EPA-HQ-OAR-2002-0058-3126
Comment Excerpt Number: 1

Comment: Ever-Green Energy considers the Standards, as proposed, to excessively favor the combustion of natural gas to the detriment of the responsible combustion of other fuels. In doing so, the proposed MACT Standard undermines other key policies at the Federal, State and local levels that encourage the development and use of renewable fuels such as the combustion of biomass. The proposed MACT Standards severely compromise the ability to develop unique energy systems such as the one Ever-Green Energy operates in Saint Paul, Minnesota; a facility that is acclaimed nationally and internationally for it's unique combination of energy efficiency coupled with renewable fuels.

The approach of the proposed MACT Standards which poses onerous requirements on a number of widely-utilized fuels also runs contrary to Federal policies that seek to improve the United States' energy security. Energy independence at the national level can best be accomplished by responsibly utilizing a variety of native fuels, especially clean renewables. The Standards as proposed will result in a trend toward increased combustion of natural gas and a decline in the use of many other fuels, including renewable fuels, that are critical in achieving a secure and reliable energy supply. The emission levels proposed in the MACT standard are not reasonable for many of the fuels that are relied upon to achieve the desired diversification of sources, including clean wood residuals that Ever-Green Energy and its affiliates rely upon.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Name: Marvis A. Lewallen
Commenter Affiliation: Clearwater Paper
Document Control Number: EPA-HQ-OAR-2002-0058-2862
Comment Excerpt Number: 1

Comment: The existence of biomass boilers to receive woody material means that hundreds of thousands of tons of forest slash is burned in controlled combustion rather than in open burn piles. As EPA research has previously established, routing biomass to boilers has a profound beneficial impact on hazardous air pollutant emissions. For example, in its paper published by Paul Lemieux of EPA's National Risk Management Research Laboratory, benzene emissions from the open burning of Douglas fir slash was estimated at 196 mg/kg. [Reference: Lemieux et al, Emissions of Organic Air Toxics from Open Burning: A Comprehensive Review; Table 6; Progress in Energy and Combustion Science 30 (2004)] The estimated benzene emissions from the controlled burning of Douglas fir slash in a biomass boiler is less than 5 mg/kg. This means that every ton of slash burned in the forest results in approximately 40 times more benzene than had that same ton been burned in a biomass boiler. By adding unduly burdensome regulations that force companies that operate biomass boilers to stop burning biomass, EPA will cause the diversion of slash to open burning with the net result being a significant increase in hazardous air pollutant emissions.

Response: The EPA thanks the commenter for their input, but the EPA did not have ample time or data to analyze the potential impacts the rule may have on open burning.

Commenter Name: Pamela F. Faggert
Commenter Affiliation: Dominion
Document Control Number: EPA-HQ-OAR-2002-0058-2908.1
Comment Excerpt Number: 1

Comment: Dominion owns and operates an 83 MW biomass facility (consisting of 3 wood-burning boilers) in Hurt, Virginia and is considering additional biomass power investments to enhance its portfolio of renewable and carbon-neutral generation. Such investments will require reasonable environmental regulations that can be met with currently available and economically feasible emissions control technology. As a matter of public policy, EPA should encourage the combustion of biomass as substitute fuel for coal or oil. The combustion of biomass will become increasingly important to utilities as renewable portfolio standards (RPS) or targets are adopted by more states and are possibly applied to all states as a result of federal mandates. The combustion of biomass may also have an important role as an option for achieving existing or anticipated greenhouse gas emission (GHG) reduction goals or targets. Biomass power is a key strategy for many utility companies, including Dominion, in the southeastern U.S., since there are more limited renewable energy resources than in other parts of the country. In addition, biomass power utilizing waste wood is currently the lowest-cost commercially available renewable generation option that is also a base-load (dispatchable) generation resource. Unfortunately, the stringent MACT limits proposed for industrial boilers burning biomass will greatly inhibit the combustion of biomass in the future and could discourage companies from combusting biomass over more traditional fossil fuels, making it increasingly difficult for companies to meet RPS and GHG requirements and/or reduction goals. The cost of adding controls for biomass could be extensive, potentially inhibiting the development of new biomass facilities.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Robert Bauer
Commenter Affiliation: Kentucky Forest Industries Association
Document Control Number: EPA-HQ-OAR-2002-0058-3186.1
Comment Excerpt Number: 1

Comment: Reduction in the use of wood and woodwaste as fuel
The proposed rules impose severe emission restrictions on the combustion of biomass. Since many facilities may not be able to afford the controls required to meet the proposed MACT limitations, it appears that the proposed rules will drive these facilities towards the combustion of natural gas to meet energy requirements. Since biomass is a renewable source of energy, this appears to run contrary to the current Administration’s stated desire to move away from fossil fuels and toward renewable sources. Kentucky, along with other States, is facing mandatory renewable energy targets in the future. For obvious reason, wind, solar, geothermal and many other renewable sources are not viable in Kentucky. Biomass appears to be the primary alternative. Our state may not be able to meet its goals if biomass usage is discouraged. Additionally, given the current Administration’s desire to regulate Greenhouse Gas emissions, it is perplexing to the Department that the EPA would drive facilities away fro utilizing what may be considered a “carbon neutral” fuel. Furthermore, when combined with the recently proposed solid waste definition, it appears that the fate of wood residuals may be landfills, where it will decay into methane, which has a CO_2 equivalence of 25:1

Response: The topic of carbon neutrality and biomass emissions is outside the scope of this rulemaking. Further, EPA recognizes that the situation of each affected entity is different, and although some facilities may opt to switch to natural gas in lieu of biomass combustion, the data show that many biomass facilities are at or below the final emission limits, suggesting that many facilities will adopt biomass fuel specifications or install controls in order to meet the emission limits. The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Kristine M. Krause
Commenter Affiliation: Wisconsin Electric Power Company, We Energies

Comment Excerpt Number: 1

Comment: We Energies is currently seeking approval to construct a 50 megawatt (MW), biomass-fired cogeneration facility at the Domtar Mill in Rothschild, Marathon County, Wisconsin. While we are concerned with many aspects of this proposed rule, We Energies is especially concerned with the potential negative impacts that the proposed rule could have on this project and other biomass projects in the future. This is an especially critical concern in states, such as Wisconsin, that have Renewable Portfolio Standards in place. In addition, the proposed rule significantly impacts We Energies' Milwaukee County Power Plant located in Wauwatosa, Wisconsin. Milwaukee County Power Plant is a cogeneration facility with three coal-fueled stoker boilers that

provide chilled water and heating steam to the Milwaukee Regional Medical Complex. There is currently no other source in place for these critical services.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Richard Lovely
Commenter Affiliation: Grays Harbor PUD
Document Control Number: EPA-HQ-OAR-2002-0058-2770.1
Comment Excerpt Number: 1

Comment: We believe that while the rule may be well intentioned, it would undermine the ability of utilities in Washington State, including Grays Harbor PUD, to comply with renewable energy mandates. It would create a disincentive for development of renewable biomass energy generation nationwide

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Name: Patrick Strauch
Commenter Affiliation: Maine Forest Products Council
Document Control Number: EPA-HQ-OAR-2002-0058-3120.1
Comment Excerpt Number: 1

Comment: Burning wood and paper mill sludge (which is a wood byproduct) replaces the use of expensive fossil fuels at many Maine mills. Wood energy is clean and has a much smaller carbon footprint than fossil fuels. The proposed rules will disadvantage existing and future wood burning boilers. We believe this will be counterproductive in the effort to reduce pollution.

First, it is important that we note that the Maine Forest Products Council represents a diverse mix of 350 forest products related companies in Maine. Concerning manufacturers, we represent companies from small individually operated saw mills, to major paper producers employing hundreds of individuals. Of the 49 total boilers that will be affected in Maine, 33 of them are boilers located in forest products facilities.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 1

Comment: The stringent limits and requirements in the proposed IB MACT decrease the prospect of producing reliable renewable energy from biomass, since the resulting limits are virtually unachievable at many sources. Without the capability of producing renewable energy from new and/or converted biomass-fired boilers, the Southeast’s renewable energy resources will be further constrained.

Implementing this rule as proposed potentially affects both existing and new biomass-fired boilers. “Existing” sources face the prospect of potentially adding additional emission controls to meet the proposed emission limits for existing sources. These controls will be costly. The stringency of the proposed limits for “new” biomass sources may actually be a disincentive to proceeding with new boilers or with boiler conversions, thus eliminating the renewable energy and greenhouse gas (GHG) reduction benefits achieved by using a carbon neutral fuel - biomass.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Name: Jeffrey R.Klieve
Commenter Affiliation: Monsanto Company
Document Control Number: EPA-HQ-OAR-2002-0058-2754.1
Comment Excerpt Number: 1

Comment: Monsanto operates several industrial boilers at various manufacturing facilities which would be impacted by the Boiler/PH MACT. This includes boilers fired with coal or natural gas with the ability to co-fire seed corn or hydrogen as alternative fuels in order to provide steam for the facilities' manufacturing operations. The alternative fuels provide important energy and heating value that reduce the amount of fossil fuels required to be burned to meet required steam demand. Firing seed corn, a renewable biomass fuel, also reduces overall emissions of greenhouse gases that would otherwise result from burning fossil fuels. Substituting hydrogen as a boiler fuel directly reduces GHG emissions as well as hazardous air pollutants (HAPs) that would occur from burning natural gas.

Response: See the preamble for discussion of combination fuel units.

Commenter Name: Deb Hawkinson
Commenter Affiliation: Hardwood Federation
Document Control Number: EPA-HQ-OAR-2002-0058-2781.1
Comment Excerpt Number: 1

Comment: Hardwood lumber is dried in kilns powered by boilers. Most boilers in the hardwood industry are run on sawdust and other waste from the production process, and many would qualify as "large" boilers (>10 million BTUs) under the proposed rule. Large amounts of fuel are needed to dry wood in the kilns, which have capacities ranging from 30,000 to 2,000,000 square feet. Some hardwood facilities use their own wood waste to fuel their boilers, while others buy all or some of their wood waste from other companies like furniture or pallet manufacturers. These manufacturers would often take their wood dust to local municipal solid waste facilities for disposal if it were not purchased by hardwood processors.

There is a significant risk that, at least for those companies who could continue operations given the higher costs of compliance, boilers would be converted from wood waste to natural gas should this rule go into effect. There are sometimes challenges in obtaining enough wood waste to power the boilers – as furniture and other wood manufacturers move overseas, lumber manufacturers must look elsewhere for wood waste. Some have come up with creative solutions, including providing free surfacing work in order to obtain wood dust. Several companies in our industry used natural gas boilers in the past, converting to biomass as costs rose. This was long before our government recognized this conversion as a positive energy step. Should costs for biomass rise, it is likely that many will stop using these renewable byproducts of wood manufacturing, preferring less environmentally friendly fossil fuels.

One small hardwood business owner who operates three manufacturing facilities with boilers running on wood waste offered the following observation:

Obviously, any added costs to drying lumber are going to reduce our already elusive profits in a declining industry. The consequences of the MACT program could cause lumber drying operations such as ours to convert back to non renewable resources such as fuel oil or natural gas. Then the wood waste would have to be disposed of in the landfill causing us to burn more diesel fuel to get it there and filling up the land fills. We currently have a very efficient system because the wood waste is often consumed at the point where it is. I can't begin to calculate how much it would cost if we had to truck our wood waste from the saw mill and concentration yard to the landfill, this would be ludicrous.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Edward Bortz
Commenter Affiliation: SP Newsprint Co LLC
Document Control Number: EPA-HQ-OAR-2002-0058-3128
Comment Excerpt Number: 1

Comment: The Rule Will result in Increased Negative Environmental Impacts
We respect EPA's job is to protect air quality. However, the existence of biomass boilers to receive woody material means that hundreds of thousands of tons of forest slash is burned in controlled combustion rather than in open burn piles. As EPA research has previously established, routing biomass to boilers has a profound beneficial impact on hazardous air pollutant emissions. For example, in its paper published by Paul Lemieux of EPA's National Risk Management Research Laboratory, benzene emissions from the open burning of Douglas fir slash was estimated at 196 mg/kg. [Reference: Lemieux et al, Emissions of Organic Air Toxics from Open Burning: A Comprehensive Review; Table 6; Progress in Energy and Combustion Science 30 (2004)] The estimated benzene emissions from the controlled burning of Douglas fir slash in a biomass boiler is less than 5 mg/kg. This means that every ton of slash burned in the forest results in approximately 40 times more benzene than had that same ton been burned in a biomass boiler. By adding unduly burdensome regulations that force wood products companies such as ours to stop burning biomass, EPA will cause the diversion of slash to open burning with the net result being a significant increase in hazardous air pollutant emissions.

Overly burdensome regulation will also result in similar increases in greenhouse gas emissions. The definitive study assessing the use of biomass to generate electricity is the May 2008 report entitled Bioenergy and Greenhouse Gases, prepared by Gregory Morris, PhD of The Renewable Energy Program of the Pacific Institute in Berkeley, California. This report notes that the use of biomass avoids the need to combust fossil fuels and also notes that because the combustion of biomass adds no net new carbon to the atmospheric-biospheric circulation system, it is considered "carbon neutral." Additionally, the study went beyond these comparatively simplistic conclusions to evaluate whether and how the change in terrestrial biomass (i.e., forest thinning) affects overall sequestration as well as the impacts of the change in timing and mix of carbon forms that occur depending on the fate of biomass. This detailed analysis concludes that greenhouse gas sequestration is enhanced by the forest thinning that generates much slash. Of greater importance, however, is the benefit achieved by avoiding open burning and/or decomposition (composting) of slash. Open burning and low-efficiency combustion (i.e., fireplaces) result in much higher emissions of methane, a potent greenhouse gas, as compared to controlled combustion in a boiler such as SSE's. Biomass that is left to decompose in the forest or is landfilled degrades into a 50-50 mixture of methane (CH_4) and carbon dioxide (CO_2). The report notes that due to the much higher global warming potential of methane, as compared to carbon dioxide, the global warming impacts associated with decomposition exceed those of controlled combustion even though less carbon is released into the atmosphere from natural decomposition over a 100-year period. In summary, Dr. Morris' team concluded that for every ton of biomass combusted to make electricity, you avoid 0.8 tons of greenhouse gas (CO_2 -equivalent) as a result of avoided fossil fuel use. For the biomass originating as slash, there is an additional net reduction of greenhouse gases of between 0.22 tons and 2.28 tons, depending on how the slash would have been handled if it had not been routed to controlled combustion. [Reference: Morris; Bioenergy and Greenhouse Gases, Table 4, Green Power Institute of The Renewable Energy Program of the Pacific Institute, May 2008]. This means that by combusting biomass our facilities reduce GHGs by 1.42 tons for every bone dry ton of slash that they combust.

It is not economical to haul biomass long distances. The closure of one of our boilers will have the immediate impact of increasing the amount of biomass that is disposed of through open burning and/or landfilling. This will have the exact opposite effect that EPA is hoping for through promulgation of the NESHAP.

Response: The EPA thanks the commenter for their input, but the EPA did not have ample time or data to analyze the potential impacts the rule may have on open burning. Furthermore, the carbon emissions from biomass is not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Comment: In addition to producing all of the electrical power required by the factory and the rest of the plantation, the Puunene Mill power plant, along with two hydroelectric plants installed in the plantation irrigation system, together provide about seven percent of the electrical power supplied to Maui residents and businesses by the local utility. Thus, power generated by the plantation comprises a significant component of the utility's state-mandated renewable energy portfolio. In addition, HC&S is seeking to transition from a commodity sugar producer to an energy plantation with the aim of increasing its already substantial renewable energy production, thereby allowing it to continue to supply a significant portion of Maui's electricity needs while eventually reducing or even eliminating the use of fossil fuels. The potential costs of compliance with the Boiler MACT may make this transition, and indeed HC&S' continued operation, infeasible. This could jeopardize the state's ability to meet its renewable energy objectives, and would also be inconsistent with the Obama administration's goals of expanding renewable energy, decreasing dependence upon foreign sources of oil, and reducing greenhouse gas emissions.

Response: See preamble for discussion on revised limits and biomass definition.

Comment: The emission levels proposed in the MACT standard are not reasonable for existing plants in that many will require substantial retrofit in order to meet the standards. Even with these substantial retrofits, the ability to consistently meet the proposed emissions standards remains in doubt due to the drastic levels to which the emission levels are being limited. In the case of the facility that Ever-Green Energy operates, the location of the facility and limited space for expansion could cause us to be unable to meet the standards. Ironically, the MACT Standard, as proposed, could cause existing energy facilities that are recognized for their energy efficiency and use of renewable fuels, such as the one in Saint Paul, Minnesota, to be made obsolete at a time when tens of millions of dollars in grants, subsidies, and incentives are being paid by the Federal government to promote such facilities.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: The use of digester gas can prevent emissions of potent methane GHGs from wastewater treatment plants, minimize sludge production, and conserve natural gas usage. Further, its use would not be expected to cause an increase in any HAPs, and any potential increase in SO2 emissions could be readily controlled by conventional means. Despite these benefits, if digester gas combustion causes a unit to be regulated under Gas 2, the gas would likely not be burned in boilers or process heaters. Instead, it would be flared resulting in an increase in both fuel usage and emissions.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: EPA has proposed HAPs standards based on whether an ICI Boiler is located at a Major or Area Source of HAPs. For New Biomass boilers at a Major Source, EPA has proposed standards for Particulate Matter ("PM"), Hydrogen Chloride ("HC1"), Mercury ("Hg"), Carbon Monoxide ("CO"), and Dioxins/Furans ("DIE") whereas similar biomass boilers at an Area Source would only be regulated for PM and CO.

Biomass fired generation is an important renewable energy resource. Having significantly more HAPs limits for biomass boilers located at a Major Source severely disadvantages companies that want to repower/modify existing generating boilers to use biomass in favor of new biomass generation at Greenfield sites even though the biomass-fired boiler at each site may be the same size and therefore, by itself be an Area Source of HAPs.

Existing generating boilers being converted to biomass firing have an advantage of a location at an already developed site, the ability to use existing equipment (such as the turbine/generator), and a knowledgeable work staff. To require these boilers to meet additional emission requirements not required by a boiler at an Area Source, increases the cost of the project and may, in same cases, prevent the conversion project from moving forward due to physical limitations that may exist to installing the additional controls required to meet the HC1, Hg, and D/F standards. The result will be a higher cost of energy from biomass-fired generation either because the boiler at the Major Source will have a higher than needed capital cost or Greenfield based biomass-fired generation will be the only type of this renewable energy. In addition, for states, such as Connecticut, that have established Renewable Portfolio Standards ("RPS") and have limited other options for in-state renewable energy, the ability of the state to meet its RPS can be harmed.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: The Proposed Limits for Biomass-Fueled Boilers Are Flawed and Will Impede the Construction of Electric Generating Biomass Units
Many states have adopted Renewable Portfolio Standards (RPS) expressly for the purpose of encouraging the development and deployment of biomass fired units as a matter of public policy. The MACT standards EPA has proposed for biomass-fired boilers will create a huge barrier to the development of renewable energy biomass projects, which will cause many to be cancelled because of the choices EPA has made in developing these proposed standards. As a matter of public policy, EPA should encourage the combustion of wood biomass. The combustion of biomass is becoming increasingly important to Duke Energy and other utilities as renewable energy laws are adopted by more states, and are possibly applied to all states as a result of federal mandates. Section 112 affords EPA great flexibility in how it establishes MACT standards for these sources even after considering the recent guidance EPA has received from the courts. The combustion of biomass has the beneficial effect of conserving natural resources. Unfortunately, the stringent MACT limits EPA has proposed for IBs burning biomass will greatly inhibit the combustion of biomass in the future. This uncertainty is causing biomass projects to be postponed and will lead to project cancellations and state renewable energy goals not being met.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: In an era of debate about anthropogenic global warming, it's unwise to put excessive demands on use of biomass and energy-intensive solid waste. US-EPA acknowledges that biomass is a carbon-neutral fuel source. Furthermore, there will be increased landfilling of biomass as well as energy-intensive solid waste under this proposal. Not only will this strain landfill space, but anaerobic decay of biomass and solid waste produces methane gas, a decidedly more potent greenhouse gas than carbon dioxide. Indeed, a strong case can be made that US-EPA should be encouraging use of biomass and solid waste as fuel rather than landfilling, in order to reduce net greenhouse gas impact.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: The proposed rule also threatens the ability of our not-for-profit, community-owned Public Utility District to meet state mandates for renewable resources. Grays Harbor PUD recently entered into a contract with Sierra Pacific to purchase the renewable biomass energy in order to comply with the Energy Independence Act. Under the Act, the PUD is mandated to provide 15 percent of the energy need to serve its customers from eligible renewable resources by 2020. The mandate stair-steps into place with 3 percent required in 2012, 9 percent by 2016 and 15 percent by 2020. The biomass energy the PUD is purchasing from Sierra Pacific Industries is considered an eligible resource under the Act and is critical for compliance with the state law. We are concerned this rule would result in the PUD having to seek another resource at likely a higher cost. This puts pressure on ratepayers and all businesses in the county that rely on the PUD for electricity.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: OFIC members are concerned with the ramifications of implementing new control technologies. In addition to significant capital cost, EPA must consider other things including energy use, availability of the expertise to install equipment, ability of companies to implement the monitoring required to determine compliance, as well as a host of other issues.

One example is implementing carbon injection to control dioxin. Carbon powder injected into the air emissions will precipitate the dioxin, literally allowing the carbon/dioxin mixture to settle out at the bottom of the stack. That sounds simple and ideal, but the process creates a significant amount of by-product, consisting of a dioxin and mercury laced carbon powder. How does a company dispose of that waste? Would it be considered a hazardous waste? Given its constituents, the by-product might need to be hauled some distance to an approved waste disposal site, creating the environmental (and economic) impacts of significant fossil fuel use.

To put this in context for effectiveness, company experts opined that the level of dioxin removed via this process was likely far less than the dioxin levels produced by backyard burning in their small rural community. EPA would be choosing a hugely expensive approach with essentially negligible human health protections but with significant safety and health concerns.

Response: See the preamble for discussion on dioxin/furan emission limits and the reduced testing program. It is expected that very few sources will install activated carbon injection for dioxin/furan control as a result of the changes made to the dioxin/furan emission limits.

Commenter Name: Thomas D. Evans
Commenter Affiliation: Coastal Resources Company
Document Control Number: EPA-HQ-OAR-2002-0058-2865.1
Comment Excerpt Number: 6

Comment: The proposed rule would probably cause many biomass boilers to convert to natural gas, because that would be the only option that they could afford. If Coastal switched, its annual natural gas cost would be $10 million, at current prices, and 150,000 tons of wood-fuel would be piled up somewhere. If all U.S. softwood panel & lumber producers switched, the incremental annual natural gas cost would be $1-2 billion, we would consume 1-2% of total U.S. natural gas withdrawals (which would significantly disrupt the natural gas market), and 20 million tons of wood-fuel would be piled up somewhere to rot, which would definitely not be "Green".

Response: EPA is not requiring fuel switching to natural gas in the final rule. Further, based on the data from best performing units in the biomass subcategory several units firing biomass are meeting the final emission limits. Therefore, EPA does not expect all of the units firing biomass to switch to natural gas as a compliance option; as a result, the EPA determined that the estimated landfilled biomass and increased natural gas usage noted by the commenter are overestimated. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Commenter Name: Dale A. Riddle
Commenter Affiliation: Seneca Sustainable Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2866.1
Comment Excerpt Number: 6

Comment: Wood is not only the preferred environmental choice of building products, it is also a superior source for energy creation. Trees are created by solar energy and they are renewable in perpetuity. Unlike steel and brick, they take very little energy to manufacture, as all you need to do is turn round wood into rectangles. And, they cause a net decrease, not increase, in global warming gases in our atmosphere.

Citizens and community leaders from all segments of the political spectrum support the use of biomass to create energy.

The United States Department of Energy has called for the doubling of electrical power generated from biomass plants. The European Union identified biomass cogeneration as a primary means of increasing energy efficiency and decreasing greenhouse gas emissions. This was stated by the EU in Directive 2004/8/EC of the European Parliament and the Council of 11 February 2004 (on the promotion of cogeneration):

"The increased use of cogeneration geared towards making primary energy savings could constitute an important part of the package of measures needed to comply with the Kyoto Protocol to the United Nations Framework Convention on Climate Change, and of any policy package to meet further commitments. The Commission in its Communication on the implementation of the first phase of the European Climate Change Programme identified promotion of cogeneration as one of the measures needed to reduce the greenhouse gas emissions from the energy sector and announced its intention to present a proposal for a Directive on the promotion of cogeneration in 2002."

This quotation demonstrates the international recognition of the benefits of cogeneration plants, such as the proposed SSE facility. It also mirrors the more local sentiment expressed by Governor Kulongoski:

"I want you to know that I am committed to making Oregon a national leader in forest biomass energy development. . . . Our forests make biomass a natural fit for Oregon. We will be able to reduce the risk of forest fires by removing dry debris — and then use that debris to generate energy, all the while creating jobs, attracting new businesses, and shifting our economy into a higher gear." Gov. Ted Kulongoski. ielth Annual Leadership Summit, Jan. 2006.

In a different forum, Government Kulongoski stated:

"I am honored to support the Seneca Sustainable Energy project. This project represents an excellent example of how we get people back to work in Oregon and continue to serve as a model for the entire country of how to grow a new economy where economic prosperity is tied directly to our commitment to a sustainable future." Governor Ted Kulongoski, November 19, 2009.

EPA needs to recognize the impact of its rules, including unintended impacts. These include increased HAP and greenhouse gas emissions in our atmosphere through additional uncontrolled combustion of biomass.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Document Control Number: EPA-HQ-OAR-2002-0058-3128
Comment Excerpt Number: 10

Comment: Our industry sector has been ravaged by the economy and the volatility of fossil fuel prices. It is simply not an option to convert to exclusively natural gas as a fuel so as to maintain a bearable level of regulation. Biomass is a low-HAP fuel and should not be unduly penalized through the NESHAP process. Doing so will result in plant closures, unemployment and further flight of manufacturing operations overseas where the level of regulation is substantially lower. EPA must bring a dose of reality to the table and recognize that the impact of its rules will be increased HAP emissions through additional uncontrolled combustion of biomass and decreased domestic employment. Congress never intended such draconian effects from the NESHAP program.

Response: EPA recognizes that the situation of each affected entity is different, and although some facilities may opt to switch to natural gas in lieu of biomass combustion, the data show that many biomass facilities are at or below the final emission limits. This suggests that many facilities will adopt biomass fuel specifications or install controls in order to meet the emission limits. Furthermore, EPA has determined that changes from the proposal have reduced economic impact on many biomass facilities; see the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Commenter Affiliation: DuPont
Document Control Number: EPA-HQ-OAR-2002-0058-2793.1
Comment Excerpt Number: 10

Comment: Imposition of the proposed emission limits on units firing LFG will very likely result in a cessation of beneficial burning of LFG in boilers and process heaters for two reasons: first, and most importantly, there is no assurance that all emission limits can be achieved even with application of emissions control technology; and second, installation of emissions controls in an attempt to meet the proposed limits will be prohibitively expensive compared to simply stopping combustion of LFG and instead increase use of natural gas. Thus this proposed rule will stop the LMOP program in its tracks relative to use of LFG as boiler and process heater fuel; result in increased criteria pollutant emissions; and result in increased GHG emissions due to flaring of the LFG and alternative use of increased natural gas. DuPont instead recommends that EPA recognize the overall environmental benefits of using LFG and treat LFG as Gas 1 with use of a work practice standard approach.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Commenter Name: David Bonistall

Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 11

Comment: Without any adjustments to the proposed rule to better accommodate these combination boilers, the owners and/or operators of these boilers may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. This unintended consequence of replacing biomass with coal is contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Holly R. Hart
Commenter Affiliation: United Steelworkers Union
Document Control Number: EPA-HQ-OAR-2002-0058-2964.1
Comment Excerpt Number: 12

Comment: It is the policy of the United States to encourage the use of biomass fuels, and if EPA regulates these units via a MACT standard it will encourage the owners to switch to cheaper fuels such as coal, just as the agency reasons a MACT standard would encourage owners of boilers in the exempted categories to switch to such fuels as coal (75 Fed. Reg. 107, June 2, 2010, p. 32025). It also will substantially discourage operators from considering any switch to biogas as fuel, a switch otherwise encouraged by the government of the United States. EPA's consideration of these and related factors in deciding its regulatory approach is mandated by CAA Section 112 (d) (2).

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1

Comment Excerpt Number: 13

Comment: The EPA Should Establish a Limited Use Subcategory. Section 112(c)(1) of the Clean Air Act provides the EPA with the authority to establish subcategories of sources for which MACT standards are to be issued. Section 112(d)(1) states that EPA may distinguish among classes, types and sizes of sources within a category or subcategory in developing MACT standards. As such, the 2004 Boiler MACT provided for boiler subcatergorization based on limited use. Specifically, under this previous rulemaking, units with a capacity factor of less than 10% had less stringent emission limits (for solid fuel units) or limited initial notification reporting requirements (for gas and liquid units). This previous rulemaking appropriately recognized that limited use units require their own subcategory because of the unique characteristics of and functions provided by these boilers and process heaters. Specifically, limited use boilers and process heaters serve as emergency, back-up, or start-up units. These boilers and process heaters operate to fill in for a regular unit when that other unit is not operational. Other limited use boilers, such as auxiliary boilers at electric generating plants, only operate to provide steam to large boilers during start-up operations. These units inherently emit low levels of HAPs because of their limited use. MidAmerican believes EPA has the authority to provide for a limited use subcategory under this proposed Boiler MACT; the decision in the Brick MACT litigation (which resulted in the vacature of the previous Boiler MACT) did not specifically address the legality of limited use categorization. MidAmerican submits that the EPA should reestablish a limited use subcategory.

The limited use subcategory should be expanded to include units having annual capacity factors less than or equal to 25 percent. The previously proposed 10 percent capacity factor is too limiting and fails to account for many utility boilers that function as an emergency, back-up, or start up boiler but operate at capacity factors greater than 10 percent.

Response: EPA agrees and has created a limited use subcategory, see the preamble for discussion.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 13

Comment: The rule is not clear if the proposed emission limits apply during <10% of maximum rated output operation. EPA should consider excluding stand-by operations from the proposed regulatory limits since the purpose of operating in this mode is to consume fuel at an absolute minimum (supporting energy and waste reduction initiatives) while being able to bring a steam boiler up to maximum capacity in a very short period of time in order to supply uninterrupted steam supply to manufacturing plants at larger integrated sites. It should also be noted that the boiler exhaust temperatures are much lower than design during these low load conditions such that an oxidation catalyst to reduce CO emissions will not be effective. Therefore, mandating a 1 ppmv CO level will require increased loads on stand-by boilers even if equipped with oxidation catalysts. This will result in increased energy consumption.

Regarding CO CEMS data, at a minimum EPA needs to exclude CO emissions requirements during periods when affected units are operated at less than 50% load as EPA had finalized in the original Boiler MACT standards in 2004. This exclusion will allow some relief for standby units. EPA should incentivize stand-by operation because this means that regulated entities have a better chance of minimizing malfunction related emissions elsewhere at their site if they have a boiler on stand-by, which can be ramped up on an as needed basis.

Response: See the preamble for discussion of CO limits.

Commenter Name: Leslie Sue Ritts

Comment: Until clean fuels are available across the country, and until the economy is strong enough to provide the capital investment for the use of such fuels, we predict a significant number of plant closures as a result of this rulemaking. We recommend a close examination of the effect of such closures on economic recovery.

Response: The limits for the final rule are revised and compliance options allow for greater flexibility for boiler operators. As such the economic impact should be reduced, see the preamble for further discussion.

Commenter Name: Holly R. Hart
Commenter Affiliation: United Steelworkers Union
Document Control Number: EPA-HQ-OAR-2002-0058-2964.1
Comment Excerpt Number: 15

Comment: It is the policy of the United States to promote the use of biomass energy. Not only is biomass renewable energy; it also, if managed properly throughout its fuel cycle, is carbon neutral. Among EPA’s obligations in CAA Section 112 (d) (2) is the requirement that it consider “non-air quality health and environmental impacts and energy requirements.”

The proposed rule as written will cause many biomass users that are able to stay in business to utilize natural gas boilers instead of biomass. The ongoing cost saving for doing so based on EPA’s own figures would be $609 million dollars per year or $1.45 million per year per boiler, a very substantial incentive. Natural gas is a fossil fuel. It is not renewable and it is not carbon neutral. In addition there are significant environmental and public issues health impacts connected with the technologies used for the drilling and extraction of the shale gas that will be needed if the proposed rule were to drive a large-scale switch to natural gas.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Document Control Number: EPA-HQ-OAR-2002-0058-2727.1
Comment Excerpt Number: 18

Comment: The rules as proposed create a disincentive to the combustion of biomass and an incentive to burn natural gas.
The wood products industry uses a higher percentage of renewable energy than any other industry. The bark, sawdust, and other byproducts generated in the manufacturing process typically provide enough fuel to fire the boilers and meet the steam demands of the facility. The combustion of these biomass fuels is greenhouse-gas-neutral, and if these materials are not burned for fuel they will be hauled to a landfill where they will anaerobically decompose to methane gas which has 21 times the greenhouse gas impact of CO_2. Substituting a traditional fuel such as natural gas for this use will increase operating costs by as much as 30%, and if the entire wood products industry changed to natural gas, it would consume a significant percentage of the total U.S. natural gas production.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 31

Comment: The proposed Boiler MACT rule does not address the potential for the GHG PSD Tailoring Rule to impact projects needed to bring boiler units into compliance with the Boiler MACT standards. Due to the amount of uncertainty associated with the GHG Tailoring Rule we are requesting EPA categorically exempt projects required to comply with Boiler MACT from the GHG Tailoring Rule and GHG PSD requirements.

Addressing this uncertainty by exempting projects required to comply with Boiler MACT from the GHG Tailoring Rule and GHG PSD requirements is critical for the long term viability of U.S. manufacturing. Otherwise these rules have the consequence of putting U.S. companies at a competitive disadvantage in the global market place. As companies review compliance strategies, the relocation of U.S. production and the associated manufacturing jobs to countries that do not have to comply with Boiler MACT may be financially attractive and there will be far less uncertainty regarding these environmental regulatory requirements.

Response: Exemptions to the GHG PSD Tailoring rule are outside the scope of this rulemaking which establishes a set of MACT floor emission limits for air toxics, or surrogates for air toxics.

Commenter Name: David Bonistall
Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 32

Comment: Compliance with Boiler MACT will require facilities to install extensive emission control equipment to meet the proposed Boiler MACT emission limits. Specifically, EPA stated in the preamble that emission control would likely require a fabric filter (FF) plus carbon injection plus wet scrubber control plus combustion improvements or carbon monoxide (CO) catalyst. The installation of this equipment could result in increases in emissions of GHGs and/or require modifications to existing air permits. Installation of additional control equipment may result in emission increases due to having to increase firing rates as a result of changes in pressure drops, increased fuel burning to meet increased electrical demand of additional control equipment, etc. In addition, facilities may be required to make operational changes in order to meet the Boiler MACT limits that could result in increases in emissions of GHGs due to fuel switching, etc. Changes to Title V air permits to address installation and operation of new control equipment may also be needed.

Response: See the preamble for discussion regarding control devices concerns.

Commenter Name: David P. Tenny
Commenter Affiliation: National Alliance of Forest Owners
Document Control Number: EPA-HQ-OAR-2002-0058-2750.1
Comment Excerpt Number: 11

Comment: NAFO is concerned that because the proposed rule's stringent, numeric emissions limitations for biomass units are largely unachievable, it would create a disincentive to the continued and expanded use of biomass fuels and, in turn, could encourage the use of higher-carbon fossil fuels. As described by Metso Power, the proposed rule would discourage, if not eliminate, new development of renewable biomass power. [See submittal for Attachment 1 at 2].

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: James Johnson
Commenter Affiliation: U.S. Beet Sugar Association
Document Control Number: EPA-HQ-OAR-2002-0058-2827.1
Comment Excerpt Number: 1

Comment: Sugarbeet processing is an energy intensive process. The energy is supplied by industrial boilers fired by coal, #6 fuel oil and natural gas. Fifty years ago, there were three times as many beet sugar factories operating in the U.S. as there are today. The twenty-two existing factories have been able to survive in large part due the energy efficiency improvements they have made.
The proposed rule, as written, has the potential to greatly impact operations at the sugarbeet processing facilities across the nation, which will result in significant costs, both for initial compliance as well as ongoing compliance. Existing operations will likely require significant physical modification in order to comply with the proposed rule requirements. Not only will this impact compliance with respect to this specific proposed rule, but may also have the result of triggering the review of additional rules, such as New Source Performance Standards and Prevention of Significant Deterioration Regulations as a result.

Response: See preamble for discussion on revised limits and biomass definition.

Commenter Name: Steven W. Koehn
Commenter Affiliation: National Association of State Foresters
Document Control Number: EPA-HQ-OAR-2002-0058-2860.1
Comment Excerpt Number: 1

Comment: NASF is concerned that the proposed Major Source rule will prevent new markets for forest biomass from developing. Unnecessarily stringent regulations in the proposed rule can be cost prohibitive and have the potential to prevent new investment in wood-based bioenergy facilities. This will cause boilers to increase their use of fossil fuels which runs counter to the nation's renewable energy goals. Further, lack of markets for biomass will increase onsite open burning which can have negative public health impacts such as the release of methane and black carbon. We strongly encourage EPA to avoid finalizing regulations that have unintended consequences that limits forest role in delaying the nation's shift to clean, renewable energy.
I. General Comments

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment: If these biomass plants are allowed to continue to be approved, the consequences will be massive deforestation and an increase in death, disease and cancer.

Response: EPA thanks the commenter for their input. Approval of permits for new biomass energy plants are outside the scope of this rulemaking and EPA has finalized emission limits for biomass units greater than or equal to 10 mmBtu/hr to be protective of human health and environment.

Commenter Name: Aubra Anthony, Jr
Commenter Affiliation: Anthony Forest Products Company
Document Control Number: EPA-HQ-OAR-2002-0058-2885.1
Comment Excerpt Number: 1

Comment: The wood products industry leads all other manufacturing industries in using renewable fuels. Industry group statistics show that in 2008, renewable fuels produced 73.5% of the needed energy at wood products facilities. U.S Department of Energy data show that wood products facilities, such as ours, produced 6% of the renewable fuel energy generated by all manufacturing facilities in all sectors.

To the determent of this industry and the nation's recent energy policies, new environmental regulatory proposals, such as the Non-Hazardous Secondary Materials Rule, the Standards of Performance for Commercial and Industrial Solid Waste Incinerators (CISWI), Boiler GACT, Greenhouse Gas Mandatory Reporting Rule (through the proposed Settlement Agreement No. 09-1333), among others, along with Boiler MACT threaten severe harm to our industry and our current renewable fuel usage strategies. This threat comes during one of the worst economic crisis ever seen by this country.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Robert C. Carroll

Document Control Number: EPA-HQ-OAR-2002-0058-2692.1
Comment Excerpt Number: 1

Comment: The wood furniture manufacturing industry uses kiln dried wood containing less than 20% moisture to generate the heat and steam necessary to manufacture our finished product. Our industry is one of the original recycling sectors in industrial manufacturing. Modern manufacturers achieve approximately 50% yield from sawmill wood stock. Rather than dispose of the remaining 50% dry wood biomass in a landfill, the biomass "off-fall" is beneficially used to produce energy. By combusting kiln dried wood in steam generating boilers, the wood furniture industry avoids the need to rely upon fossil fuels for process and domestic heating purposes. Combustion of our wood fuel also precludes land filling the wood off-fall, which would add environmental insult to the injury of being prevented from using a valuable fuel commodity.

Response: It is not our desire to preclude operators from burning biomass. The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Comment Excerpt Number: 1

Comment: RE-Gen is concerned that the EPA's proposed rules will:

Diminish our country's energy security

Affect our efforts to meet our nation's state Renewable Standard Portfolios

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Commenter Name: Arthur Blazer
Commenter Affiliation: Council of Western State Foresters
Document Control Number: EPA-HQ-OAR-2002-0058-2832.1
Comment Excerpt Number: 1

Comment: The forestry sector in the Western U.S. has been in transition for many years, and in some places is at or below critical industry infrastructure to support the necessary forest management practices to sustain healthy forests. Market options for small diameter, lower value products, and expanded renewable energy markets will help diversify existing forest industry and provide economical alternatives to achieve sustainable, healthy forests in our country.
For example, vast areas of federal, state and private forests in the Western U.S. are identified for fuels reduction that reduces wildfire risk to communities and protects critical forest resources. Large landscapes are being impacted by bark beetle; removing the hazard trees generates large volumes of wood materials that currently have few local options for value-added products. Options for local, small-scale energy uses such as heating school campuses, prisons, and greenhouse complexes are a cost effective way of utilizing the forest and manufacturing residues, while contributing to community and state renewable energy goals. Larger bioenergy facilities also have a role in the western landscape in the form of combined heat and power, industrial boilers, and community energy systems, and are currently one of the major producers of renewable energy for the United States.
The draft Area Source and Major Source Rules will directly impact the cost and viability of existing and new systems. Unfortunately, these rules potentially have the unintended consequence of providing no options for using forest residues other than slash pile burning in the forest. This option alone cannot provide our nation with the resources needed to maintain healthy forests and help meet renewable energy standards. Although the rulemaking process such as the MACT standards are not required to look at these trade-offs and the alternative fates, the reality is that clean burning of forest biomass in modern high efficiency biomass boilers creates many benefits for society beyond renewable energy because it reduces this alternative source of emissions while producing renewable energy.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Chris Welch
Commenter Affiliation: Colorado Springs Utilities
Document Control Number: EPA-HQ-OAR-2002-0058-2943.1
Comment Excerpt Number: 2

Comment: To meet these emissions limits would require extensive process modifications, installation of controls and additional costs to meet stack testing requirements. Initial analysis shows a more cost effective solution to be removal of these boilers from service, installation of flares and utilization of electricity from the nearby power plant. The disincentive to utilize these boilers created by the proposed rule would result in additional emissions since the biogas would be flared and additional fuel would be burned at the power plant, and would be contrary to the goals of this MACT and the Clean Air Act.

Response: See the preamble for discussion of achievability of emission limits, how we adjusted CO levels, and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Commenter Name: Linda Barnfather
Commenter Affiliation: Washington House of Representatives
Document Control Number: EPA-HQ-OAR-2002-0058-2852.1
Comment Excerpt Number: 2

Comment: As the state has invested in the renewable energy field, we have looked to the forest products sector to take a leadership role. In particular we have focused on renewable biomass power as an arena where we have a competitive advantage and an ability to increase distributed domestic power generation and utilization of previously wasted forestry resources.
A 2005 state biomass inventory found that as a state we are "blessed with a vast and diverse, annually renewable biomass, which although in places is presently utilized for energy, fertilizer and feed, in other places is still quite underutilized and capable of being a significant factor in bioenergy, biofuel, or bioproduct production." The inventory found that Washington State has an annual production of over 16.9 million dry tons of underutilized biomass which could be capable of creating 15.5 billion kWh of electrical energy, or almost 50% of the state's annual residential energy consumption. [Footnote: http://www.ecy.wa.gov/pubs/0507047.pdf]
This focus on biomass power has resulted in significant levels of public and private investment.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Document Control Number: EPA-HQ-OAR-2002-0058-2856.1
Comment Excerpt Number: 2

Comment: Overly burdensome regulation will also result in similar increases in greenhouse gas emissions. The definitive study assessing the use of biomass to generate electricity is the May 2008 report entitled Bioenergy and Greenhouse Gases, prepared by Gregory Morris, PhD of The Renewable Energy Program of the Pacific Institute in Berkeley, California. This report notes that the use of biomass avoids the need to combust fossil fuels and also notes that because the combustion of biomass adds no net new carbon to the atmospheric-biospheric circulation system, it is considered "carbon neutral." Additionally, the study went beyond these comparatively simplistic conclusions to evaluate whether and how the change in terrestrial biomass (i.e., forest thinning) affects overall sequestration as well as the impacts of the change in timing and mix of carbon forms that occur depending on the fate of biomass. This detailed analysis concludes that greenhouse gas sequestration is enhanced by the forest thinning that generates much slash. Of greater importance, however, is the benefit achieved by avoiding open burning and/or decomposition (composting) of slash. Open burning and low-efficiency combustion (i.e., fireplaces) result in much higher emissions of methane, a potent greenhouse gas, as compared to controlled combustion in a boiler such as SSE's. Biomass that is left to decompose in the forest or is landfilled degrades into a 50-50 mixture of methane (C114) and carbon dioxide (CO_2). The report notes that due to the much higher global warming potential of methane, as compared to carbon dioxide, the global warming impacts associated with decomposition exceed those of controlled combustion even though less carbon is released into the atmosphere from natural decomposition over a 100-year period. In summary, Dr. Morris' team concluded that for every ton of biomass combusted to make electricity, you avoid 0.8 tons of greenhouse gas (CO2equivalent) as a result of avoided fossil fuel use. For the biomass originating as slash, there is an additional net reduction of greenhouse gases of between 0.22 tons and 2.28 tons, depending on how the slash would have been handled if it had not been routed to controlled combustion. [Reference: Morris; Bioenergy and Greenhouse Gases, Table 4, Green Power Institute of The Renewable Energy Program of the Pacific Institute, May 2008]. This means that by combusting biomass our facilities reduce GHGs by 1.42 tons for every bone dry ton of slash that they combust.

Response: The EPA did not have ample time or data to analyze the potential impacts the rule may have on open burning. However, the emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 2

Comment: These actions will greatly increase the growth in demand for Natural Gas, a fossil fuel. In spite of the fuel crisis of a couple of year ago, and the Enron Crisis of a decade ago, this action will have the unintended consequence of driving more energy control into the hands of a few. From recent experience, we know that the price of Natural Gas can "sky-rocket" and catch companies mid-stream and drive many to bankruptcy. This is certain.

Response: EPA recognizes that the situation of each affected entity is different, and although some facilities may opt to switch to natural gas in lieu of biomass combustion, the data show that many biomass facilities are at or below the final emission limits. This suggests that many facilities will adopt biomass fuel specifications or install controls in order to meet the emission limits. Furthermore, EPA has determined that changes from the proposal have reduced economic impact on many biomass facilities; see the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 for further discussion on biomass.

Comment Excerpt Number: 2

Comment: This proposed rule seems in direct conflict with the Administration's stated goal to increase the amount of greener, cleaner and sustainable energy generated within our own borders. Specifically, the rule will have a significant, negative impact on biomass fueled facilities. This rule will penalize biomass units because they start with a cleaner fuel; specifically when the inlet concentration of a pollutant is low (as is the case with biomass), it becomes exponentially more expensive to remove those concentrations and difficult to prove removal at the outlet (when outlet concentrations are below the analytical detection limit).

The rule will subject all biomass units to emission standards that are based on the very best performing, new biomass units. However, not even those best performing units can meet the proposed limits 100% of the time, nor do the best performing units comply with all the emission standards simultaneously, resulting in a standard that is unachievable. Rather than encouraging biomass generated power, this rule will have the opposite effect. When one compares the standards set forth in the rule for fossil fuel fired natural gas units versus biomass, it would be logical for investors to shy away from green, carbon neutral biomass fired units in favor of natural gas, fossil fuel-fired units. Yet, we know that natural gas and other fossil fuels are irreplaceable, unlike biomass which can be regrown.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 2

Comment: Our alternatives to complying with the major source rule are not at all advantageous, efficient or affordable either. One alternative to huge investments in control equipment is to deliberately reduce our allowable production capacity to a level that would make us a non-major HAP source, but also non-competitive once the market picks up. We would then be subject only to the area source rules, that may prove to also be very expensive for us also. Other alternatives are not much better, but would include major changes in the processes for the sake of eliminating boilers at our site altogether. Again, we are talking about extremely expensive propositions in a down economy.

Response: See the preamble for discussion on revised limits.

Commenter Name: Catherine W. McCuthen

Comment: We respect EPA's job is to protect air quality. However, the existence of biomass boilers to receive woody material means that hundreds of thousands of tons of forest slash and/or wood residuals from sawmills is burned in controlled combustion rather than in open burn piles. As EPA research has previously established, routing biomass to boilers has a profound beneficial impact on hazardous air pollutant emissions. For example, in its paper published by Paul Lemieux of EPA's National Risk Management Research Laboratory, benzene emissions from the open burning of Douglas fir slash was estimated at 196 mg/kg. [Reference: Lemieux et al, Emissions of Organic Air Toxics from Open Burning: A Comprehensive Review; Table 6; Progress in Energy and Combustion Science 30 (2004)] The estimated benzene emissions from the controlled burning of Douglas fir slash in a biomass boiler is less than 5 mg/kg. This means that every ton of slash burned in the forest results in approximately 40 times more benzene than had that same ton been burned in a biomass boiler. By adding unduly burdensome regulations that force wood products companies or integrated papermills such as ours to stop burning biomass, EPA will cause the diversion of wood residues to open burning with the net result being a significant increase in hazardous air pollutant emissions or to landfills.

Response: The EPA thanks the commenter for their input, but the EPA did not have ample time or data to analyze the potential impacts the rule may have on open burning.

Comment: Overly burdensome regulation will also result in similar increases in greenhouse gas emissions. The definitive study assessing the use of biomass to generate electricity is the May 2008 report entitled Bioenergy and Greenhouse Gases, prepared by Gregory Morris, PhD of The Renewable Energy Program of the Pacific Institute in Berkeley, California. This report notes that the use of biomass avoids the need to combust fossil fuels and also notes that because the combustion of biomass adds no net new carbon to the atmospheric-biospheric circulation system, it is considered “carbon neutral.” Additionally, the study went beyond these comparatively simplistic conclusions to evaluate whether and how the change in terrestrial biomass (i.e., forest thinning) affects overall sequestration as well as the impacts of the change in timing and mix of carbon forms that occur depending on the fate of biomass. This detailed analysis concludes that greenhouse gas sequestration is enhanced by the forest thinning that generates much slash. Of greater importance, however, is the benefit achieved by avoiding open burning and/or decomposition (composting) of slash. Open burning and low-efficiency combustion (i.e., fireplaces) result in much higher emissions of methane, a potent greenhouse gas, as compared to controlled combustion in a boiler such as ours. Biomass that is left to decompose in the forest or is landfilled degrades into a 50-50 mixture of methane (CH_4) and carbon dioxide (CO_2). The report notes that due to the much higher global warming potential of methane, as compared to carbon dioxide, the global warming impacts associated with decomposition exceed those of controlled combustion even though less carbon is released into the atmosphere from natural decomposition over a 100-year period. In summary, Dr. Morris’ team concluded that for every ton of biomass combusted to make electricity, you avoid 0.8 tons of greenhouse gas (CO_2-equivalent) as a result of avoided fossil fuel use. For the biomass originating as slash, there is an additional net reduction of greenhouse gases of between 0.22 tons and 2.28 tons, depending on how the slash would have been handled if it had not been routed to controlled combustion. [Reference: Morris; Bioenergy and Greenhouse Gases, Table 4, Green Power Institute of The Renewable Energy Program of the Pacific Institute, May 2008]. This means that by combusting biomass our facilities reduce GHGs by 1.42 tons for every bone dry ton of slash that they combust.

Therefore, we strongly urge EPA to consider the comments below on how to revise the Boiler and Process Heater NESHAP so as to minimize the potential for boiler closures. It is not economical to haul biomass long distances. The elimination of biomass fuel in our boiler will have the immediate impact of increasing the amount of biomass that is disposed of through open burning and/or landfilling. This will have the exact opposite effect that EPA is hoping for through promulgation of the NESHAP.

Response: The EPA did not have ample time or data to analyze the potential impacts the rule may have on open burning. However, the emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Bruce A. Steiner
Commenter Affiliation: American Coke and Coal Chemicals Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2849.1
Comment Excerpt Number: 3

Comment: Importantly, efforts made to switch from flaring coke oven gas or other process gases to combusting it in the more carefully controlled setting of a boiler will also benefit the environment in two ways. First, it will reduce the potential for inefficient combustion at the flare, which is exposed to wind and other elements that may interfere with complete combustion. Also, supplemental fuel at a flare is typically limited to the pilot light and is not available to help ensure a stable flame. As a result, EPA's emission factors assume up to 98% control of organic compounds from flares combusting gases with the heat values characteristic of coke oven gas. See EPA, AP-42 at 13.5-4 (citing EPA's Flare Efficiency Study, EPA-600/2-83-052). By contrast, properly tuned boilers achieve 99.9% combustion efficiency for organic compounds from gaseous fuels. See EPA, AP-42 at 1.4-3. This means that flares would be expected to emit 20 times the organic compounds that would be emitted from a boiler. Second, energy recovery in boilers will supplant the need for combustion of additional fossil fuels, thus eliminating the greenhouse gases, criteria pollutants, and HAP emissions associated with those fuels. For example, a 545 MMBTU/hr coke oven gas-fired boiler generating electricity will supplant 334,310 megawatt-hours of electricity previously purchased from the grid and reduce coal combustion by 260,000 tons per year. This one coke oven gas-fired boiler would reduce 357,240 tons of carbon dioxide emissions each year and many additional tons of other pollutants of concern.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: RE-Gen is concerned that the EPA's proposed rules will:

Derail the effort to strengthen the health of our forests and agricultural lands

Distract our fight to better climate change

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: David P. Tenny
Commenter Affiliation: National Alliance of Forest Owners
Document Control Number: EPA-HQ-OAR-2002-0058-2750.1
Comment Excerpt Number: 3

Comment: Forests can play an important role in reducing and managing greenhouse gas emissions. Expanding the sources of renewable energy is a central feature of both national and international policy to reduce reliance on fossil fuels.

The EPA, in considering approaches toward addressing climate change, has long recognized that responsibly managed forests are considered one of five key “groups of strategies that could substantially reduce emissions between now and 2030.” See Regulating Greenhouse Gas Emissions Under the CAA, 73 Fed. Reg. 44,354, 44,405 (July 30, 2008). Similarly, the United Nation’s Intergovernmental Panel on Climate Change (“IPCC”) report on mitigation technologies highlights forest management as a primary tool to reduce GHG emissions. Id. at 44,405-06; see also NAFO, Carbon Mitigation Benefits of Working Forests (identifying trading platforms and registries that recognize forest management), available at http://nafoalliance.org/mitigation-benefits-working-forests/.

President Obama has emphasized that renewable energy derived from feedstocks such as forest biomass hold the key to transitioning the nation to a “sustainable, low carbon energy future.” See Letter from President Barack Obama to Governors John Hoeven and Chet Culver (May 27, 2009), available at http://www.governorsbiofuelscoalition.org/assets/files/President%20Obama’s%20Respo nse5-27-09.pdf; see also President Barack Obama, Memorandum for the Secretary of Agriculture, the Secretary of Energy, and the Administrator of the Environmental Protection Agency, 74 Fed. Reg. 21531-32 (May 5, 2009).

With Presidential endorsement, if not direction, of national renewable energy policy and the role of biomass in that policy, EPA must conduct its programs in a manner consistent with that policy. In light of this policy, EPA must not adopt any mandatory environmental controls, such as those set forth in the proposed rulemaking, that will require large expenditures of time and resources by industry, but are not necessary to protect human health and the environment. Similarly, to act consistently with this nation’s renewable energy policy, EPA must not impose restrictions on biomass boilers that are not legally required and that stand to disadvantage the use of biomass as a fuel source. The proposed rule lacks any justification for its departure from this policy and, as explained below, is thus arbitrary and capricious.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Christopher S. Bond
Commenter Affiliation: United States Senator
Document Control Number: EPA-HQ-OAR-2002-0058-2958.1
Comment Excerpt Number: 3

Comment: EPA’s imposition of standards so expensive that they force forest-product facilities to abandon their use of biomass to power their operations would drive those that survive to more carbon-intensive energy sources such as coal, predominant in Missouri, or propane. Not only would facilities release more carbon from their energy sources, but the carbon from the biomass byproduct would still be released into the atmosphere after it is discarded. Thus, EPA’s proposal threatens both the administration’s goal of encouraging renewable, lower-carbon fuels and reducing carbon emissions.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Michael Potter
Commenter Affiliation: Goodyear Tire and Rubber Company
Document Control Number: EPA-HQ-OAR-2002-0058-3181
Comment Excerpt Number: 3

Comment: Goodyear believes that promulgation of the proposed rules will greatly increase the usage of natural gas in the regulated boilers, straining the availability of natural gas and thereby significantly increasing the frequency, duration and severity of natural gas curtailments and supply interruptions in the future. Other possible future EPA regulations, such as regulations related to greenhouse gas emissions, could exacerbate this situation even further. Because Goodyear cannot predict the timing or duration of gas curtailments and interruptions at its various plant locations, and cannot predict what enforcement actions EPA or State Agencies may take in response to notifications submitted under section 63.7545(f), the proposed regulations may require Goodyear to install exorbitantly costly emission control systems to meet oil subcategory standards just to protect plant operations from possible disastrous production curtailments. This enormous investment might be needed just to preserve existing fuel oil back up capabilities even though the controls may seldom be used, if ever.

Response: EPA is not requiring fuel switching to natural gas in the final rule. Further, based on the data from best performing units in the biomass subcategory several units firing biomass are meeting the final emission limits. Therefore, EPA does not expect all of the units firing biomass to switch to natural gas as a compliance option and increased natural gas usage will be minimal. Also note that emission limits for oil boilers have been revised, see the preamble for discussion.

Commenter Name: Joe Muehlbach

Comment: We strongly urge EPA to consider the comments below on how to revise the Boiler and Process Heater NESHAP so as to minimize the potential for boiler closures. It is not economical to haul biomass long distances. The closure of one of our boilers will have the immediate impact of increasing the amount of biomass that is disposed of through open burning and/or landfilling This will have the exact opposite effect that EPA is hoping for through promulgation of the NESHAP.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Mary L. Frontczak
Commenter Affiliation: Peabody Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2897.1
Comment Excerpt Number: 4

Comment: EPA’s discrimination against coal will evidently have its desired effect. EPA projects that "... the majority of new boilers and process heaters will be built to fire natural gas as opposed to solid and liquid fuels." According to the Agency, no new coal-fueled units will be built in the next three years, while 33 new natural gas/refinery gas units will be built. Fuel switching caused by the Boiler MACT rule will increase natural gas demand by .65 TCF to .85

TCF in a relatively short time period and will bring the country to a level of natural gas demand that EIA has not forecast until 2025.

Response: It is necessary to note that the limits of this rule were not a factor in projecting the number of new major source units. Rather, projections were based on the economic outlook of the energy sector.

Document Control Number: EPA-HQ-OAR-2002-0058-2692.1
Comment Excerpt Number: 4

Comment: There has been considerable discussion regarding the classification of biomass as a carbon-neutral fuel. The carbon neutral classification of biomass will not be settled in this forum. However, we can definitively assert that the proposed rule will reduce or eliminate the use of dry biomass fuel in the wood furniture manufacturing industry, and a significant portion of the displaced fuel source will be replaced by fossil fuels such as natural gas or coal. It is wrong to argue that replacement of biomass fuel with fossil fuels would not increase GHG emissions.

Response: The carbon emissions from biomass are not within the scope of this rulemaking. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source, and see the preamble for the revised limits.

Comment: EPA should exercise its discretion to establish health based emission limits (HBEL). The unintended consequences that HCl controls may prevent recycling of combustion wastes. Coal ash from uncontrolled coal combustion sources is desirable for recycling in the cement manufacturing industry. In many instances, wet scrubbers will change the characteristics of this waste, making recycling infeasible.

Response: A health based compliance option is not provided, see the preamble for discussion.

Commenter Name: Bruce A. Steiner
Commenter Affiliation: American Coke and Coal Chemicals Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2849.1
Comment Excerpt Number: 4

Comment: If EPA finalizes a rule that subjects coke oven gas-fired boilers to the stringent numeric emissions limitations proposed for Gas 2 sources, the additional cost of controls would functionally eliminate these valuable efforts to reclaim energy. The U.S. Department of Energy has awarded competitive grant funds to energy recovery projects that convert flared coke oven gas to usable steam and electricity. The Proposed Rule would discourage the type of energy recovery project that DOE is actively trying to promote. This is because the annualized cost of control required to meet the Gas 2 emission limits exceeds the cost of replacement natural gas for many units. Facing this economic reality, coke oven gas will be flared and natural gas will be combusted to generate steam to the detriment of the environment and our national goals of energy independence.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Commenter Name: Dan F. Hunter
Commenter Affiliation: ConocoPhillips Company

Comment Excerpt Number: 4

Comment: The low CO alternate emission limit would have the effect of raising other pollutants, including NOx, CO_2 and HAP (the very pollutant statutorily targeted for reduction) because inefficient operation of units at this low CO level will require more fuel to be burned for the same heat output. Additionally, other surmised control measures would require increased energy to operate, require significant space requirements, potential demolition costs and facility process shutdowns. In fact, the very projects needed to install such controls would likely emit more emissions that could be reduced over the life of the equipment for gas-fired sources. Such factors have apparently not been considered by EPA.

Response: See the preamble for discussion on CO limits.

Comment: We are especially concerned that the proposed changes make take affect as the Administration's support of biomass has been unwavering and involves almost every member of the Cabinet from the White House, USDA, DOE, Interior, Council on Environment Quality, EPA, DOJ, Treasury and Commerce. As well, in Congress biomass has been included in every single piece of renewable energy legislation beginning with the Public Utility Policy Act of 1978. Support for biomass is universal, bi-partisan, and spans the scope of virtually every major energy policy enacted by the Congress.

RE-Gen urges, in light of the overwhelming support for biomass from every corner of government, that EPA adopt a rule that provides flexible approaches that appropriately address the diversity of boilers, operations, sectors, and fuels that could prevent severe job losses and countless dollars in unnecessary regulatory costs. In this regard, we ask you to consider three particular issues as presented by The Biomass Power Association on August 23, 2010.

Response: See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Martha E. Rudolph
Commenter Affiliation: State of Colorado
Document Control Number: EPA-HQ-OAR-2002-0058-2940.1
Comment Excerpt Number: 5

Comment: EPA should not overlook possible deleterious environmental effects of new regulations that overly constrain existing and emerging technologies that use woody biomass for the production of renewable energy and other purposes. As Governor Ritter and the Western Governors' Association have repeatedly communicated, Colorado and the Inter-mountain West face forest health problems of monumental proportion. Landscape-scale insect infestations, disease, decades of fire suppression, and persistent drought have left Colorado forests in a state of elevated risk for catastrophic wildfire. Not only do such
intense fires compromise ecological health and watershed functionality, they pose risk for people, their communities and public infrastructure located within or adjacent to forested land. Importantly, they also are sources of PM, CO_2, CO, NOx, S02, and other pollutants in amounts and concentrations that dwarf emissions typically associated with biomass boilers and other means of controlled combustion of woody biomass. Since public financial resources are insufficient to underwrite large scale hazardous fuels reduction and forest thinning projects that are critical to reducing these risks and to restoring forested landscapes to healthier conditions within generally accepted ranges of natural variability, private investment tied to the potentially profitable use of woody biomass is a vital public policy objective. Unfortunately, more stringent air quality standards, if not clearly warranted from a public health standpoint, could dramatically impact the ability of private operators and local communities to use locally harvested materials

for heating or small scale power generation since the cost of the advanced control technologies are, in many instances, more expensive than the entire project. EPA should thus take a very rigorous look at whether, and if so in what instances, woody biomass should be included in, or excluded from, these proposed rules.
To further underscore the importance of the role of woody biomass use in managing Colorado's forest health issues, see the submittal for the August 10, 2010 letter from Governor Ritter to the U.S. Secretary of Agriculture, Thomas Vilsack.

Comment Excerpt Number: 5

Comment: Importantly, efforts made to switch from flaring coke oven gas to combusting it in the more carefully controlled setting of a boiler will also benefit the environment in two ways. First, it will reduce the potential for inefficient combustion at the flare, which is exposed to wind and other elements that may interfere with complete combustion. As a result, EPA's emission factors assume just 98% control of organic compounds from flares combusting gases with the heat values characteristic of coke oven gas. See EPA, AP-42 at 13.5-4 (citing EPA's Flare Efficiency Study, EPA-600/2-83-052). By contrast, properly tuned boilers achieve at least 99.9% combustion efficiency for organic compounds from gaseous fuels. See EPA, AP-42 at 1.4-3. Based on these EPA emission factors, flares would be expected to emit 20 times the organic compounds that would be emitted from a boiler. Second, energy recovery in boilers will supplant the need for combustion of additional fossil fuels, thus eliminating the greenhouse gases, criteria pollutants and HAP emissions associated with those fuels. For example, 545 MMBtu/hr coke oven gas-fired boiler generating electricity will supplant 334,310 megawatt hours of electricity previously purchased from the grid and offset 260,000 tons of coal combustion per year. This one coke oven gas-fired boiler would reduce 357,240 tons of CO_2 emissions annually and many additional tons of other pollutants of concern.

If EPA finalizes a rule that subjects coke oven gas-fired boilers to the stringent numeric emissions limitations proposed for Gas-2 sources, the additional cost of controls would functionally eliminate these valuable efforts to reclaim energy. The U.S. Department of Energy has awarded competitive grant funds to energy recovery projects that convert flared coke oven gas to usable steam and electricity. The Boiler MACT rule as proposed would discourage the type of energy recovery project that DOE is actively trying to promote. This is because the annualized cost of control required to meet the Gas-2 emission limits exceeds the cost of replacement natural gas for many units. Facing this economic reality, coke oven gas will be flared and natural gas will be combusted to generate steam to the detriment of the environment and our national goals of energy independence.

Comment Excerpt Number: 5

Comment: EPA has clearly established a disincentive for installation of new biomass boilers, which conflicts with the Obama administration's and Congress' intention to move towards greater renewable energy usage and reduction in fossil fuel usage. By establishing new source limits that are not realistically achievable by a new emission unit, EPA is promoting the reliance on older, less efficient energy/steam generating sources as well as units with emission profiles that are generally worse than new units. It is unlikely that this was the Congressional intent when establishing the requirements of CAA Section 112.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Kevin M. Dempsey
Commenter Affiliation: American Iron and Steel Institute

Comment Excerpt Number: 5

Comment: If EPA finalizes a rule that subjects coke oven gas-fired boilers to the stringent numeric emissions limitations proposed for Gas 2 sources, the additional cost of controls would functionally eliminate these valuable efforts to reclaim energy. The U.S. Department of Energy has awarded competitive grant funds to energy recovery projects that convert flared coke oven gas to usable steam and electricity. The Proposed Rule would discourage the type of energy recovery project that DOE is actively trying to promote. This is because the annualized cost of control required to meet the Gas 2 emission limits exceeds the cost of replacement natural gas for many units. Facing this economic reality, coke oven gas will be flared and natural gas will be combusted to generate steam to the detriment of the environment and our national goals of energy independence.

The economic analysis is clear. The Proposed Rule sets numeric emission limits for 5 pollutants (PM, HCl, Hg, dioxin/furans, and CO). At this time, coke oven gas-fired units are not controlled for these compounds. Using EPA's projected cost of control (annualized capital cost plus annual operating cost) for each pollutant, including monitoring, recordkeeping and reporting, an AISI member company has calculated an annualized cost of control at $8.6 million for a single 650 MMBTU/hr unit combusting coke oven gas. [The capital cost for the unit is $27,747,000 and the annual non-capital cost is $5,678,000.] At a natural gas cost of $5/MMBTU (costs have been much higher in recent years), it is economically unreasonable for the boiler operator to use coke oven gas to displace the first 1,720,000 MMBTU per year of natural gas in this boiler or in blast furnace gas-fired boilers using coke oven gas, and the coke oven gas would be flared. The use of natural gas to replace coke oven gas in this situation would be to the detriment of the environment and our energy policies.

The constraint on available capital is an additional impediment to the installation of emission control equipment because increased natural gas consumption does not require a capital investment. Before a company will invest $8.6 million in annualized control costs for a single boiler, it will need to justify a return on the capital investment far greater than $8.6 million per year in displaced natural gas. Moreover, there is no expectation that expenditures of this magnitude will be sufficient to meet the proposed Gas 2 subcategory emission limits.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: At a time when all government agencies should be focused on job creation and economic recovery, EPA's currently proposed regulation will have the opposite effect, further depressing business conditions, resulting in more business closings and job losses. The negative economic impacts will not be limited to those companies that fall under the proposed Boiler MACT, but also the wood and biomass residual suppliers that would be devastated by the downsizing or closing of these facilities.

Response: The emission limits and compliance options are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Tom Midyett
Commenter Affiliation: Tennessee Paper Council
Document Control Number: EPA-HQ-OAR-2002-0058-2691.1
Comment Excerpt Number: 8

Comment: The EPA proposed means of developing emission limits is so overly stringent, that the proposed Boiler MACT rule will drive some Tennessee paper mills to eliminate the use of a site-generated secondary biomass material as a fuel. In the case of one specific Tennessee mill, this will result in land filling approximately 16000 tons of mill-produced material annually. The rule may also necessitate the use of more natural gas as a fuel instead of recycled and native biomass (wood material) as a fuel. Such fuel switching will result in significant additional energy costs to the mills and will result in a loss of business to recyclers/biomass fuel providers who sell their products to the mills instead of land-filling them. The unintended consequence of replacing biomass with coal or gas is directly contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 8

Comment: EPA has proposed biomass limits so stringent as to choke this burgeoning industry before it even has an opportunity to develop. . As a matter of public policy, EPA should encourage the combustion of biomass as a substitute for fossil fuels. The combustion of biomass will become increasingly important to utilities as renewable energy standards are adopted by more states or in federal legislation. The combustion of biomass is sustainable with the beneficial effect of conserving natural resources. Unfortunately, the stringent MACT emission limits EPA has proposed for ICI Boilers burning biomass will greatly inhibit the combustion of biomass in the future.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Commenter Name: Alicia Oman
Commenter Affiliation: National Association of Manufacturers

Comment Excerpt Number: 9

Comment: Biomass is a “clean” fuel in many of the same respects as the Gas 1 fuels. Biomass-fired boilers produce no net GHG emissions, which makes the combustion of biomass an important tool in managing and reducing the Nation’s carbon footprint. Similarly, biomass is an abundant, renewable domestically-produced fuel that can help reduce reliance on foreign sources of fossil fuel and, thus, improve the Nation’s energy security. Prescribing stringent HAP emissions limitations on biomass boilers will create a significant barrier to the continued use and expansion of biomass fuels and incentivize the use of less desirable fossil fuel alternatives.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 9

Comment: EPA’s focus on individual HAPs has resulted in a failure to recognize the critical interplay between emissions controls and emissions of other pollutants. For example, we are concerned that the controls necessary to meet the stringent emissions limitations for CO will result in increased energy usage, with the concomitant increase in emissions of NOx and other pollutants. Further, EPA failed to account for this interrelationship in its economic analysis.

Response: See the preamble for discussion on CO limits and interactions of control devices.

Commenter Name: David P. Tenny
Commenter Affiliation: National Alliance of Forest Owners
Document Control Number: EPA-HQ-OAR-2002-0058-2750.1
Comment Excerpt Number: 9

Comment: The combined effect of these arbitrary and unnecessary controls would substantially increase the cost of using biomass as a fuel source. As such, the proposed rule would negate the several government programs providing incentives to use biomass and to develop technologies reliant on biomass. With devalued incentives and increased costs, the nation would risk losing biomass as an integral part of renewable energy policy. The effect of the proposed rule would ultimately land at the foot of the forest landowner as biomass markets fail to grow or even disappear as heat and power facilities turn to other fuel sources. Most forest landowners calculate a return on their investment on a variety of markets for forest products. The elimination or dramatic reduction of a significant market such as biomass could affect the attractiveness of forestland ownership to the degree that owners look to use of the land for purposes other than forests in order to obtain an economic return.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Document Control Number: EPA-HQ-OAR-2002-0058-2872.1
Comment Excerpt Number: 13

Comment: The rules as proposed create a disincentive to the combustion of biomass and an incentive to burn natural gas.

The wood products industry uses a higher percentage of renewable energy than any other industry. The bark, sawdust, and other byproducts generated in the manufacturing process typically provide enough fuel to fire the boilers and meet the steam demands of the facility. The combustion of these biomass fuels is greenhouse-gas-neutral, and if these materials are not burned for fuel they will be hauled to a landfill where they will anaerobically decompose to methane gas which has 21 times the greenhouse gas impact of CO_2. Substituting a traditional fuel such as natural gas for this use will increase operating costs by as much as 30%, and if the entire wood products industry changed to natural gas, it would consume a significant percentage of the total U.S. natural gas production.

Response: The emission limits are revised for the final rule, see the preamble for discussion. See the response to EPA-HQ-OAR-2002-0058-2860.1, excerpt 6 regarding biomass as a renewable energy source.

Comment Excerpt Number: 14

Comment: During start-up, shutdown, and malfunction (SSM) periods, boilers and process heaters operate at off-design conditions with low firing rates and high excess air levels. At these low loads, mixing energy of the fuel and air in the combustion process is much lower. CO will increase during this operation. To further exacerbate this, in multi-burner boiler installations the industry code on combustion safety (NFPA - National Fire Protection Association) does not allow air flow reduction below 25% of design (this is purposely done to avoid explosive fuel-rich scenarios). Therefore high-excess air operation (and CO) during these periods is unavoidable. In addition, good operating practices require that equipment be gradually warmed up to operating temperature in order to prevent thermal damage in mechanical components. Equipment vendors require this gradual warm-up for equipment warranty. This proposed rule will limit the life of units due to a need to increase start-up rates creating increased stresses. Also, attempting to meet 1 ppm CO during SSM periods would discourage proper start-up and shutdown of equipment as operators would quickly ramp-up/down boilers to minimize off-design operation. This is important because the majority of combustion safety incidents, both near-misses and explosions, occur during SSM periods.

Response: EPA has revised the CO limits for the final rule, see the preamble for discussion. Also see the preamble for discussion on SSM.

Comment: Reducing CO to extremely low levels will require increased excess air levels which reduce efficiency, increasing the amount of fuel that must be fired and therefore increasing the total mass of other pollutants (i.e. HAPs, CO_2, NOx, SO_x, PM, etc.). Efforts to maximize boiler efficiency, and reduce NOx emissions, have also been accomplished by reducing excess air levels until the point where CO emissions begin to increase. Operation at excess air levels which result in CO emissions in the 100-400 ppm range provides the most efficient balance between stack heat loss and loss of potential energy from incomplete CO oxidation. (see submittal for Figure 9, showing HAPs at this CO range (100-400).

Comment: PPG believes that it is likely for many boilers that the optimum point for energy efficiency will require facilities to perform at levels that are not optimum for emissions of other pollutants. Tuning of boilers is important and routinely conducted at major facilities, but it is often done to minimize emissions of traditional combustion pollutants such as NOx and CO, which occurs at a higher oxygen level than maximum energy efficiency. These pollutants are nearly always held in check by each other. The most energy efficient operation often times does not result in the lowest levels of either NOx or CO emissions. If facilities were required to maximize boiler efficiency emissions of certain of these pollutants will increase. EPA has failed to note such issues or consider them in the proposal.

Response: See the preamble for discussion on tune-ups.

Commenter Name: Paul N. Cicio

Document Control Number: EPA-HQ-OAR-2002-0058-3122
Comment Excerpt Number: 29

Comment: Fly ash disposal. The proposed regulation will create fly ash that is not suitable for beneficial reuse. EPA regulations in 40 CFR §63.1344(g) and §63.1350(o) generally prohibit use of fly ash when sorbents are used for mercury control. This appears to be at odds with the EPA position taken "that the beneficial use of CCRs (and, in particular, specific beneficial uses of CCRs, such as using fly ash as a substitute for Portland cement in the production of concrete) provide significant environmental benefits, including the reduction of GHG emissions" (75 FR 35160).
EPA should consider the negative environmental impact caused by the proposal in setting the mercury standard. The mercury standard should not be so stringent as to require sorbent use for control. The mercury standard should be set to allow conventional pollution control devices (baghouses, ESPs) to achieve the standard while still allowing beneficial reuse of fly ash in an environmentally positive way. The cost benefit analysis should include the additional cost of fly ash disposal under the proposed mercury standard, which may change from a revenue producer to an operating cost. The cost and social impact of additional greenhouse gases, etc., should also be included.

Response: See the preamble for discussion on revised limits and control devices.

Commenter Name: Richard L. Killion

Comment: Implementation of the industrial MACT would not necessarily decrease fuel usage. One of the means to control CO is to increase excess air to the unit which would decrease unit efficiency and increase fuel usage. The allowance for decreased fuel usage should be removed or reduced from the engineering cost analysis.

Response: See the preamble for discussion on CO limits and their impact on emissions.

Commenter Name: David M. Kiser
Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 32

Comment: As a nation, we have stated goals of energy conservation, limiting our greenhouse gas emission footprint, recycling and decreasing our dependence on foreign sources for energy. In addition, the global economy is just starting to come out from under the shadow of the worst economic recession in decades. The economy is fragile and job preservation and growth are key for the economy to recuperate and grow. All of these are laudable goals and objectives to have as a nation. However, this suite of proposed rules, including but not limited to the Boiler MACT rule, are inconsistent with these objectives.

The Boiler MACT rule requires "coal boilers", defined as any unit that burns more than 10 % coal on a heat input basis, to meet a CO limit that is not achievable in practice with combustion controls for boilers co-firing biomass. As a result the Boiler MACT rule provides strong disincentive to continuing to burn biomass. In fact to do so International Paper (and EPA) believe such boilers would need to be retrofit with combustion catalysts which cost on the order of $15 million each and which require addition of natural gas burners to reheat cleaned and cooled exhaust gases to nearly 500 to 750 degrees F in order to burn trace residual organic HAP that may be present. Reheating fuel gas alone will cost on the order of $5 million per year per unit for natural gas and as a result will contribute to increases in NOx and CO_2 emissions to such a degree that a typical pulp mill combination fuel boiler will need to undergo new source review permitting for GHG in order to install controls to meet the Boiler MACT rule. This technology review would be likely to discount the value of the combustion catalyst as it will significantly degrade the energy efficiency of the boiler. Then one rule will be requiring a control that another rule would suggest should not be built. This result would of course be untenable. The increased NOx and CO_2 also represent an increased adverse environmental impact or detriment associated with the Boiler MACT rule. (EPA apparently did not understand that combustion catalysts require roughly 500 degree gas temperatures to combust CO and higher temperatures on the order of 750°F to control organics HAPs.)

Response: See the preamble for new subcategory definitions and discussion of CO limits.

Comment Excerpt Number: 32

Comment: EPA has assumed would be available to meet HCl limits may in fact be unavailable due to constraints on wastewater discharges.

part 429.11(c) so that the discharge prohibition in 40 CFR part 429 would not apply to wastewaters associated with air pollution control devices (APCD) operation and maintenance when used to comply with the final Boiler MACT rule. § 429.11 General definitions should be amended to read as follows (changes highlighted in Bold/Underline):
"(c) The term "process wastewater" specifically excludes non-contact cooling water, material storage yard runoff (either raw material or processed wood storage), boiler blow down, and wastewater from washout of thermal oxidizers or catalytic oxidizers, wastewater from biofilters,

wastewater from air pollution control devices on boilers and process heaters or wastewater from wet electrostatic precipitators used upstream of thermal oxidizers or catalytic oxidizers installed by facilities covered by subparts B, C, D or M to comply with the national emissions standards for hazardous air pollutants (NESHAP) for plywood and composite wood products (PCWP) facilities (40 CFR part 63, subpart DDDD); for Industrial, Commercial, and Institutional Boilers and Process Heaters at major source facilities (40 CFR 63 Subpart DDDDD) and
for Industrial, Commercial, and Institutional Boilers at area sources (40 CFR 63 Subpart JJJJJJ). For the dry process hardboard, veneer, finishing, particleboard, and sawmills and plaining mills subcategories, fire control water is excluded from the definition.

Background

The effluent guidelines for the Timber Products Processing Point Source Category in 40 CFR part 429 subparts B (Veneer subcategory), C (Plywood subcategory),
D (Dry Process Hardboard subcategory), and M (Particleboard Manufacturing subcategory), prohibit the discharge of process wastewater pollutants. We believe that the effluent limitations for these wastewaters should be developed by permit writers on a case-by-case basis based upon best professional judgment. This issue was adequately addressed and resolved for the PCWP MACT Rule where the EPA excluded the definition of process wastewaters in 40 CFR 29.11(c) for the wastewaters associated with APCD used by PCWP facilities covered by subparts B, C, D, and M to comply with 40 CFR 63.22: wastewater from washout of thermal oxidizers and catalytic oxidizers, wastewater from biofilters, and wastewater from WESP used upstream of thermal oxidizers or catalytic oxidizers. Refer to 69 FR 45964, for more details. EPA specifically excluded
wastewater generated by three processes and associated APCDs necessary to meet the PCWP NESHAP from coverage by the existing effluent limitations
guidelines. These three processes and associated process wastewaters are: (1) washing out RTOs or RCOs; (2) WESPs used upstream of RTOs/RCOs to protect them from plugging with particulate; and (3) biofilters. The resulting amended definition of process wastewater is shown below:

§ 429.11 General definitions.

* * * * *

(c) The term “process wastewater” specifically excludes non-contact cooling water, material storage yard runoff (either raw material or processed wood storage), boiler blow down, and wastewater from washout of thermal oxidizers or catalytic oxidizers, wastewater from biofilters, or wastewater from wet electrostatic precipitators used upstream of thermal oxidizers or catalytic oxidizers installed by facilities covered by subparts B, C, D or M to comply with the national emissions standards for hazardous air pollutants (NESHAP) for plywood and composite wood products (PCWP) facilities (40 CFR part 63, subpart DDDD). For the dry process hardboard, veneer, finishing, particleboard, and sawmills and plaining mills subcategories, fire control water is excluded from the definition.

We believe the same data used for the PCWP MACT rule can be used for the Boiler MACT in that the issue and argument are essentially the same. It will be extremely difficult for structural and engineered wood panels manufacturing facilities to meet the proposed Boiler MACT rule without allowing the discharge of wastewater from APCD used to meet Boiler MACT. Control of PM and HCl to achieve the proposed Boiler MACT emission limits, will require the use of a wet device. The use of a wet electrostatic precipitator may require the discharge of at least 10 gallons per minute of blow down or 14,400 gallons per day.

As stated in the preamble to the PCWP MACT rule, until effluent limitations guidelines and standards for pollutants in process wastewaters from structural and engineered wood panels manufacturing facilities are promulgated, Best Practicable Technology (BPT) and BAT effluent limitations should be established on a case-bycase basis under 40 CFR 125.3. This way, individual facilities seeking a discharge permit will have the opportunity, on a case-by-case basis, to characterize and obtain discharge allowances for their wastewaters from APCD installed to comply with the final Boiler MACT standards. The permit writer would be expected to determine, based upon best professional judgment (BPJ), the appropriate effluent limitations for these APCD wastewaters. (See 40 CFR 125.3.) The permit writer can take into account facility-specific information on wastewater volumes and pollutants, available wastewater control and treatment technologies, costs and effluent reduction benefits, receiving water quality, and any applicable State water quality standards. EPA should consider amending the existing effluent limitations guidelines and standards for the Timber Processing Industry to cover process wastewaters. Such an effort would involve gathering and analyzing the information and data necessary to establish revised categorical effluent limitations affecting subparts B, C, D, and M of 40 CFR part 429 for these APCD wastewaters generated in complying with the final Boiler MACT standards. GP recognizes that this change ultimately will require communication with the appropriate staff in the Office of Water.
GP urges EPA to adopt changes to the Effluent Guidelines for Timber Products Processing. Specifically, we request that EPA amend the definition of process wastewaters at 40 CFR part 429.11(c) so that the discharge prohibition in 40 CFR part 429 would not apply to wastewaters associated with air pollution control devices (APCD) operation and maintenance when installed to comply
with the final Boiler MACT rule. § 429.11 General definitions should be amended to read as follows (changes in bold):
"(c) The term "process wastewater" specifically excludes non-contact cooling water, material storage yard runoff (either raw material or processed wood storage), boiler blow down, and wastewater from washout of thermal oxidizers or catalytic oxidizers, wastewater from biofilters, wastewater from air pollution control devices on boilers and process heaters or wastewater from wet electrostatic precipitators used upstream of thermal oxidizers or catalytic oxidizers installed by facilities covered by subparts B, C, D or M to comply with the national emissions standards for hazardous air pollutants (NESHAP) for plywood and composite wood products (PCWP) facilities (40 CFR part 63, subpart DDDD); for Industrial, Commercial, and Institutional Boilers and Process Heaters at major source facilities (40 CFR 63 Subpart DDDDD); for Industrial, Commercial, and Institutional Boilers at area sources (40 CFR 63 Subpart JJJJJJ). For the dry process hardboard, veneer, finishing, particleboard, and sawmills and planing mills subcategories, fire control water is excluded from the definition.

Comment Excerpt Number: 35

Comment: As was noted with respect to small remote incinerators, island/remote facilities have very similar issues relating to water and to solid waste. In the case of remote Alaska facilities, it is the inability to use wet gas scrubbing because of cold weather. For island facilities such as HOVENSA, water is extremely scarce and must be produced by desalination. The cost of this water and the emissions from producing it are significant. Wastewater (generated from a wet scrubber for example) would have to be treated at the refinery as no municipal treatment plant in St. Croix could accept it. Likewise, HOVENSA is not located near industrial solid waste facilities and must typically ship these wastes thousands of miles at high cost to receiving facilities elsewhere. Thus, control dusts from baghouses or ESP systems would have to be shipped elsewhere.

Response: See the preamble for discussion on the new non-continental states and territories subcategory.

Comment Excerpt Number: 36

Comment: By establishing new source limits that are not realistically achievable by a new emission unit, EPA is promoting the reliance on older, less efficient energy/steam generating sources as well as units with emission profiles that are generally worse than new units. U.S. Sugar and all other facilities that may wish to retire older units to install new boilers would be prohibited from doing so under the unachievable proposed Boiler MACT. For example, Boiler No. 8 at the Clewiston facility was designed to be the most efficient bagasse boiler when it began commercial operation in 2005. The unit has state-of-the-art control technology to meet the Best Available Control Technology (BACT) requirements of the Prevention of Significant Deterioration program. While it is acknowledged that new source MACT is different than BACT, the best controlled units for PM and CO should also be the “best controlled similar source”.

Therefore, even if U.S. Sugar wanted to install new boilers with the capabilities of the best boiler currently operating, the unachievable proposed standards of the Boiler MACT would preclude these environmentally beneficial projects. This is obviously not the Congressional intent when establishing the requirements of CAA Section 112.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Commenter Name: Sarah E. Amick

Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 37

Comment: EPA provides no justification for restricting averaging to a given subcategory nor is it rational to impose such a restriction. Emissions averaging generally allows a facility to avoid otherwise cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination. It also has corresponding environmental benefits, by creating an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from a coal-fired unit. If the Boiler Rule does not allow averaging across the different fuel categories, EPA removes that incentive for sources to turn to cleaner-burning fuels to achieve averaging benefits.

Response: EPA has determined it is not appropriate to allow emission averaging across subcategories. EPA does not do this in other rules with mixed streams (e.g., SOCMI) and the commenter does not provide sufficient justification for swaying from this precedent.

Commenter Name: Douglas J. Van Pelt

Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 39

Comment: EPA's proposed emission limits, particularly for Gas 2 sources and considered for Gas 1 sources, by themselves result in non-optimum operation of boilers/process heaters by increasing fuel consumption and other pollutants (e.g. NOx). EPA should modify the proposed rule to encourage efficient boiler/process heater operation in the base case with the appropriate boiler tune-up requirements instead of numeric emission limits that result in inefficient operation. EPA's analysis did not factor in higher costs due to increased fuel consumption and emission increases associated with non-optimum boiler/process heater operation.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Commenter Name: Jim Griffin

Comment: The limits being proposed in this rule will mandate combinations of emission controls that have adverse effects on each other. In short, the presence of one control technology may prevent a second control technology from operating at optimum performance.

A primary control for Hg emissions involves the injection of activated carbon into the flue gas. The mercury is oxidized on the active sites on the carbon particles. The oxidized form of mercury can then either be recovered by particulate control equipment or by a scrubber (since oxidized mercury is soluble). The oxidation reactions only occur at temperatures below about 350ºF. The effectiveness of the activated carbon for oxidizing mercury is dependent upon the amount of time that the carbon has to attract the mercury to one of its active sites.

The use of activated carbon injection for mercury control is negatively affected by the presence of sulfur trioxide (SO_3). SO_3 occupies the active sites on the carbon, taking away those sites from the mercury. Even a few parts per million of SO_3 can have a significant negative impact on the mercury removal to be achieved by activated carbon injection. For example, due in part to inherently higher SO_3 emissions, Stoker fired boilers see reduced Hg reduction compared to pulverized coal (PC) boilers. Other control devices, such as CO oxidation catalyst or SCR NOx reduction catalyst, will convert an additional percentage of the SO2 to SO3, resulting in poor mercury removal. EPA can avoid this problem by establishing standards on the basis of a source approach that properly accounts for the impact of multiple controls and the interactions between fuel sulfur, chloride, mercury, and alkali metals, as suggested earlier in these comments.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: Large integrated chemical plant sites strive to be as energy efficient as possible. One way to promote energy efficiency is to capture off-gas from petrochemical and chemical plant off-gas streams and re-use these streams as fuel in a variety of combustion sources. Plant sites are designed to use many types of "Gas 2" streams as a fuel in order to have energy efficient operations. If Gas 2 fuels are subjected to stringent emission limits instead of work practice requirements, the rule likely will force facilities to dispose of process off-gases in other types of combustion sources including flares, which results in more natural gas being used, inefficient operations, and an increase in greenhouse gas emissions.

Response: See the preamble for discussion of achievability of emission limits and how we modified the gas 1 subcategory to be more inclusive of other fuel types.

Comment: EPA has seemed to focus on criteria pollutants in many of its justifications for establishing certain limits. Shouldn't those limits be established in accordance to an equivalent reduction in HAPs? For instance, did EPA set PM standards based on PM or metals? The same can be said for CO, as it is generally well known that burners must be operated at temperatures well above those needed to destroy organic HAPs.

Response: EPA has based its PM and CO limits on the best performing units in each subcategory for each of these pollutants. EPA has determined that PM is an appropriate surrogate for non-Hg metals and that CO is an appropriate surrogate for non-dioxin organic HAP. By reducing emissions of PM and CO, emissions of these other HAP will decrease. See response to comments related to the appropriateness of surrogates under codes 6A-6Z.

Comment: We object to the U.S. EPA using only health risk assessments as its only measure of public health impacts. HRAs are not based on any public health baseline from a scientifically conducted health survey of impacted environmental justice communities. HRAs do not identify all public health impacts by illness category; do not identify how many people are afflicted, and cannot tell you if cancer is increasing or decreasing.

We request the U.S. EPA include a health impact assessment to provide information not provided in a health impact assessment. You quote in there -- as one of my final things -- that you would be avoiding 110 to 300 premature deaths in 2003. Obviously, the staff did not look at our figures in the harbor. We average that number of deaths every single day in the L.A. harbor community. So before quoting a number you need to look at the actual data, which you're going to get from the Los Angeles County Department of Health and the California Department of Health. And those will provide you reliable numbers. And with regard to the health assessments you will be describing, will you have some further description as to what those assessments should be considering?

MR. MARQUEZ: Yes. There is a provided consulting firm, Health Impact Partners, that conducts these. And U.C.L.A. and U.C. Berkeley both have institutes or departments within the universities that also specialize in health assessments.

So that you do know, U.S. EPA Region 9 last year attended a class and sent about six to seven members. As well as L.A. County Department of Health sent about four to five staff members, in addition to about 15 of us E.J. organizations and attended a class

here in Los Angeles. Actually, it was about two years
ago. And in all of the public comments that have been
made regarding that course and movement, they have
recommended a health impact assessment to perform in
addition to an HRA.

Response: EPA agrees that it is informative to estimate how many fewer people would experience air pollution-related health effects as a result of this regulation. The regulatory impact analysis conducted as part of the rule includes a health impact assessment, which quantifies a variety of health effects avoided by the rule, including mortality, hospital visits, asthma attacks, school loss days, among others at the national level. It is important to note that air pollution is only one of many contributing causes of mortality and morbidity.

Comment: For those of us that like to exercise outside, the reduction of these pollutants is not just an academic or legalistic discussion. I bicycle to work on a daily basis, from Maryland, across the District of Columbia, and into Virginia. On one hand, that exercise is substantially improve my physical fitness; but on the other hand, lungful of lead, cadmium, dioxide, and God knows what else, certainly doesn’t do much for my well being.

As I said at the outset, I’m not an expert -– medical expert, a chemical engineer, but I am an accountant by training and profession. The EPA, to their credit, has done an in-depth cost-benefit analysis of these proposed regulations. Without going into great detail, it’s pretty clear that the benefits to be achieved on an overall or on a large scale –- on a macro basis far outweigh the cost of implementation.

Obviously there's going to be local dislocations as we've heard one of the previous speakers point out; but I think if we look at the large picture, this is not something that,, in fact, is a cost but a long-term benefit.

We just finished watching the political drama of enacting major health care reform legislation. If nothing else, we've come away from that conversation with a clear, clear understanding that the long-term cost of health care in this country is measured in the hundreds of billions of dollars. And anything that we can do to reduce that cost will have a resounding and positive economic impact. These rules are going to do that.

We've waited way too long for these rules to be proposed by EPA. This is not something radical. This is not dangerous. This is not economically destructive. These rules are just plain common sense. It's common sense that we don't want our kids -– my kids – breathing mercury. It's common sense that formaldehyde is not good for anyone's lungs, and it's just common sense that the economic cost of an asthma attack triggered by minimally regulated particulates is simply unacceptable these days.

Response: EPA agrees that exposure to particulates and toxic air pollutants can cause severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: These boilers and incinerators produce particulate matter -– tiny bits of solids and aerosols formed by the sulfur dioxide and nitrogen oxide emissions. Particulate matter is the most dangerous of the widespread air pollutants. Particulate matter triggers asthma attacks, heart attacks, and strokes, among other damage, but most critically, particulate matter kills. Breathing find particles increases the risk that children with asthma and older adults with chronic obstructive pulmonary disease or cardiovascular disease will end up in the emergency room or the hospital.

These units also spread mercury and lead, hazardous metals that can harm children's brains, hurting their IQ and limiting their ability to learn and to remember what they have learned. Cleaning up these boilers and incinerators will save lives. EPA estimates that between 2,000 and 5,000 lives will be saved every year because of the changes put in place by these requirements beginning in 2013.

But that's only part of the benefits. Having less pollution to breathe should benefit –- should prevent over 3,000 non-fatal heart attacks, avoid over 35,000 cases of worsened asthma, and eliminate nearly 3,400 hospital and emergency room visits each year –- each year.

Response: EPA agrees that exposure to particulates and toxic air pollutants can cause severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: So let me just focus on something that EPA itself concluded. The major source boiler rule will save 4,800 lives every year -– 4,800 lives that would be lost prematurely if this rule were weakened or as industry seeks, there were a health-based exemption thrown in. And that's just the tip of the iceberg because when EPA counted the number of lives that would be saved, it only looked at the emission reductions of fine particulate matter.

It didn't look at the 7 tons of mercury that would be reduced or the literally thousands of tons of lead and arsenic and chromium that we reduced, or the dioxins, or the formaldehyde, or the benzene. Yet all of these things have very serious health effects. These metals can cause cancer. So can benzene and formaldehyde and dioxins. Mercury can cause birth defects and developmental damage in children. So, if the real health effects were taken into account, we'd be looking at a lot more than 5,000 lives saved. We don't know how many it is because EPA doesn't quantify or monetize it.

But let me get back to the monetization also because those 4,800 lives are worth billions more than the cost to industry will be. In fact, by EPA's calculations even with just 4,800 lives the ratio is about 5 to 1 or 10 to 1 in terms of benefits to costs. It would be far more overwhelming if the full benefits were calculated.

Response: EPA agrees that exposure to particulates and toxic air pollutants can cause severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: The new rules will protect students and residents who live near and downwind from those coal –- excuse me -– coal-burning boilers. Emissions of toxic air pollution such as mercury, arsenic, cadmium, and acid gases, would be significantly reduced. These pollutants are extremely dangerous, and EPA's actions will help remove thousands of pounds of toxics from the air, including 15,000 pounds of mercury and tens of thousands of tons of acidic gases that cause breathing problems, particularly in vulnerable individuals like children and the elderly. About 36,000 asthma attacks could be prevented each year and result in approximately $18 to $44 billion in health savings annually, according to the EPA's analysis.

Mercury is an extremely dangerous neurotoxin that can impact a child's ability to walk, talk, read, write, and learn. The mercury problem in the United States is so pervasive that one in six women today have mercury levels in their blood high enough to put her baby at risk, according to the EPA. High mercury levels have also been linked to an increased risk of heart disease in men.

We need drastic reductions in toxic pollution and greenhouse gas pollution, and these boilers are a major source of this pollution, even if not individually, then cumulatively. There are nearly 14,000 major source boilers alone around the country. Even the smaller types of boilers burning coal and waste present a grave threat to human health and the environment. Toxins like mercury and selenium are harmful even in small doses, and many of these facilities are located in very highly populated areas.

Response: EPA agrees that exposure to particulates and toxic air pollutants can cause severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: The technology is available off the shelf for all of those size boilers; and yes, it will cost a little bit of money to do it, but it essentially is going to -– hopefully, even in doing a cost-benefit analysis you look at our toxic rules and the CBAs actually show that there are tremendous values to having protective rules.

And so I think it's really about creating a rule that's genuinely protective and at the very least having an inventory of all the facilities across this country of what they're burning, in what quantities they're burning.

Response: EPA agrees that exposure to fine particulates and toxic air pollutants is associated with severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: I wanted to come as a private citizen because, I mean, I live in D.C. When you look around, we are impacted by petrochemical industries and chemical industries not because they're right here in our back yard but because they're basically upwind and because we're downwind, we're failing at our air toxics tests.

There are reasons why basically our lungs are being poisoned and they're not because of emissions that are happening right here in our back yards. And a lot of it are coming from boilers and incinerators that aren't being regulated with off-the-shelf technology. And for us, it's just really important to see communities protected.

I'm a person who's of childbearing age. I am probably going to be having kids in the next five years. I have no idea what pollutants are going into my lungs, what those pollutants are going to have on my reproductive system, what they are going to have on my potential children down the line. And as I get older, it just gets more distressing that the EPA basically has the authority to move forward with promulgating protective rules, yet we're seeing things like the definition of solid waste that genuinely are protective of people.

Response: EPA agrees that exposure to fine particulates and toxic air pollutants is associated with severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: We know that powerful industry lobbies are lining up to oppose these rules. They want the loopholes and exemptions. We want the rules -– they want the rules weakened and delayed.

These rules will prevent about 4,800 unnecessary deaths each -– every year and will save billions of dollars in costs -– medical costs, time costs, costs to communities in terms of lost time and lost -– and lost ability to externalities to be able to work, live, and play in a safe environment.

The benefits overwhelm the costs by a ratio of between 5 and 10 to 1. And that's only the tip of the iceberg. It only reflects the health benefits by reducing major source boilers' emissions of fine particulate matter. It doesn't count the benefits of eliminating more than seven tons of mercury emissions every year that cause birth defects in babies and developmental damage in young children, or thousands of tons of lead, cadmium, and other metals that are known as suspected carcinogens, or the dioxins and other organic pollutants that cause cancer.

Response: EPA agrees that exposure to particulates and toxic air pollutants can cause severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: Wood products release dioxin when they are incinerated in the presence of chlorine [See reference 15 provided by commenter]. Lignin is the organic substance that makes up woody tissue. Burning chlorine in the presence of certain precursors to dioxin, including lignin, releases dioxin into the environment [See reference 16 provided by commenter]. In incinerators, the amount of dioxin formed by burning seems to depend largely on the chlorine content in the waste that is burned [See reference 17 provided by commenter]. The paper and pulp industry use chlorine to bleach paper. Id. When the paper is incinerated, the chlorine and lignin create dioxin [See reference 18 provided by commenter]. Similarly, burning lumber treated with pentachlorophenol, which the lumber industry uses to preserve wood, creates dioxin [See reference 19 provided by commenter]. Burning wood releases dioxins [See reference 20 provided by commenter]. This fact demonstrates that the burning of wood in incinerators, even when the wood is not processed by the paper and pulp industries, can result in the creation of dioxin.

Dioxin is highly toxic and can cause reproductive and developmental problems, damage the immune system, interfere with hormones and also cause cancer [See reference 21 provided by commenter]. Once dioxin has entered the body, it persists a long time because of its chemical stability and its ability to be absorbed by fat tissue, where it is stored in the body. The Department of Human Health and Services determined that it is reasonable to expect dioxin to cause cancer, among many other adverse health effects [See reference 22 provided by commenter].
Dioxin contamination has far-reaching consequences. A study by the North American Commission for Environmental Cooperation showed that dioxin from United States sources, including the combustion of wood, contaminate Inuit traditional foods such as caribou and fish, and lead to high concentrations of dioxins in Inuit mothers' milk [See reference 23 provided by commenter].

Response: EPA agrees that exposure to particulates and toxic air pollutants can cause severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: EPA overestimated health benefits.
* EPA argues that the large costs of this rule are justified by the co-benefits of PM reductions. Ironically, add-on controls for gas units would actually cause PM to increase. Moreover, there is still much uncertainty in the science community over EPA's extrapolation of mortality risks to low ambient levels, but the costs are much more certain.

Response: In many instances, it is not possible to quantify and monetize all of the benefits associated with a regulatory action due to data, resource, and methodological limitations. For this rule, we were only able to monetize the benefits associated with reducing exposure to PM2.5 as a result of reducing direct PM2.5 emission and PM2.5 precursor emissions such as SO2. If we were able to fully monetize all of the benefit categories, the benefits would exceed the costs by an even greater amount than we currently estimate.

EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. Co-benefits that occur as a result of a regulatory action are appropriate to include in the RIA, and it is appropriate to compare the total monetized benefits with the costs.

The weight of scientific evidence strongly supports modeling PM-related mortality and morbidity by using concentration-response functions that do not incorporate an assumed threshold. In 2009, the final Integrated Science Assessment for Particulate Matter indicated that "[o]verall, the studies evaluated further support the use of a no-threshold log-linear model…" (U.S. EPA, 2009). In 2010, the Health Effects Subcommittee of the Science Advisory Board "fully supports EPA's decision to use a no-threshold model to estimate mortality reductions. This decision is supported by the data, which are quite consistent in showing effects down to the lowest measured levels. Analyses of cohorts using data from more recent years, during which time PM concentrations have fallen, continue to report strong associations with mortality. Therefore, there is no evidence to support a truncation of the CRF" (EPA-SAB-COUNCIL- 10-001). Our approach to estimating PM-related health impacts is consistent with the key findings in these reports. In addition, our approach is consistent with the on-going PM NAAQS review.

In conjunction with the commenter's concern and consistent with recent scientific advice, we have replaced the previous threshold sensitivity analysis with a new "lowest measured level" (LML) assessment. While an LML assessment provides some insight into the level of uncertainty in the estimated PM mortality benefits, EPA does not view the LML as a threshold and continues to quantify the PM-related mortality impacts using the full range of modeled air quality concentrations.

In the regulatory impact analysis, we account for the emission disbenefits to the extent feasible.

Comment: 4. It is a significant and questionable shift for the EPA to attempt to justify regulations under HAP reduction authority on a basis other than HAP reductions. The CAA provides different authorities and different procedures for addressing criteria pollutants and HAPs. Congress established separate procedures to allow optimization of the requirements addressing these very different types of pollutants and to minimize the disruption to the economy by applying inappropriate approaches to each. Basing HAP rules on their estimated criteria pollutant impacts circumvents Congress‘s intent and the procedures for addressing criteria pollutants established by the CAA. The benefits associated with criteria pollutant reductions have already been claimed under the NAAQS rulemakings and procedures and it is inappropriate to claim the same benefits again.

Recommendations: Reevaluate this proposal based only on its HAP impacts.

Response: In many instances, it is not possible to quantify and monetize all of the benefits associated with a regulatory action due to data, resource, and methodological limitations. For this rule, we were only able to monetize the benefits associated with reducing exposure to PM2.5 as a result of reducing direct PM2.5 emission and PM2.5 precursor emissions such as SO2. If we were able to fully monetize all of the benefit categories, the benefits would exceed the costs by an even greater amount than we currently estimate.

EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. Co-benefits that occur as a result of a regulatory action are appropriate to include in the RIA, and it is appropriate to compare the total monetized benefits with the costs.

Comment: The potential magnitude of the net social benefits associated with a standard set with the UPL at the 95th (or 90th) percentile is notable. Although the benefits from reducing mercury emissions by 7.5 tons/year have not been monetized by US EPA in its Regulatory Impact Analysis (RIA), the RIA indicates that the annualized net benefits from reducing PM2.5 and its precursors would yield a net benefit on the order of $14 billion to $38 billion (2008$, 3% discount rate, in 2013), compared to a total social cost of only $2.9 billion. If the net benefits of reducing mercury are at all proportional to those for PM2.5 and its precursors, a further 38.4% reduction in mercury emissions (assuming implementation of a 95th percentile UPL rather than a 99th percentile UPL) would potentially yield billions of dollars in additional net social benefit. Such social benefits would include not only the monetized economic and social effects US EPA considered in its RIA, but also real-world improvements in population health, ecosystem sustainability, and visibility (US EPA, 2010a).

Response: EPA agrees that the monetized net social benefits are notable and that we were unable to quantify the benefits associated with mercury reductions. Although the mercury benefits would be substantial, it is unlikely that mercury benefits (if monetized) are proportional to the monetized PM benefits due to the size of the exposed population and the severity of the health effects.

Comment: EPA argues that the large costs of this rule are justified by the co-benefits of PM reductions. Ironically, add-on controls for gas units would actually cause PM to increase. Moreover, there is still much uncertainty in the science community over EPA's extrapolation of mortality risks to low ambient levels, but the costs are much more certain.

Response: EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. In many instances, it is not possible to quantify and monetize all of the benefits associated with a regulatory action.

After reviewing the scientific literature, EPA has determined that the no-threshold model is the most appropriate model for assessing the mortality benefits associated with reducing PM2.5 exposure. In the final rule, we have incorporated a new "lowest measured level" assessment to highlight the fraction of benefits that occur at low concentrations of PM2.5. This analysis shows that most of the PM-related benefits would accrue to populations exposed to higher levels of PM.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 223

Comment: The lack of health benefits from for the requirements proposed for gas-fired equipment have been hidden by only discussing health benefits on a total proposal basis. There is negligible health benefit associated with the proposal for gas-fired boilers and process heaters because there are negligible HAP and criteria pollutant reductions associated with those units. In particular, most of the claimed benefits for this proposal come from EPA's estimated PM2.5 reductions. Yet, PM2.5 emissions from gas-fired units are negligible in the base, so any reductions will be even more negligible. In fact, where emission controls are imposed on gas-fired equipment, PM2.5 emissions are likely to increase because of the PM created by the controls.

Recommendation: EPA should evaluate the proposal health benefits on a subcategory basis and demonstrate that there are net pollutant reductions and therefore potential health benefits for any subcategory it regulates.

Response: In the regulatory impact analysis for the proposal, we provide pie charts (Figures 6-4 and 6-5) to illustrate the fraction of monetized PM2.5 benefits by subcategory, including gas boilers.

Commenter Name: Matthew Todd and David Friedman

Comment: EPA did not appropriately consider health impacts resulting from increased NOx, CO_2 and HAP emissions from meeting proposed extremely low CO limits on units where add-on controls are not installed. Nor have the health impacts been evaluated of increased dioxin/furan emissions due to lowering the stack temperatures of boilers and process heaters to accommodate the add-on controls necessary to attempt to comply with this proposal. Nor has the health impact of increased particulate emissions from gas-fired units as the result of installing activated carbon controls or oxidation catalyst been considered.

Recommendation: Incorporate the health disbenefits of this proposal into the record and rulemaking analyses.

Response: In the regulatory impact analysis, we account for the emission disbenefits to the extent feasible.

Comment: The majority of the claimed health benefits of this proposal are derived from the co-benefits of reducing PM2.5 and PM2.5 precursors. These reductions are anticipated to result from the installation of controls to limit HAP emissions. To calculate the economic benefits of reducing PM2.5, EPA used a risk assessment approach that extrapolates health impacts to the lowest levels of PM2.5 observed in air quality modeling. This non-threshold based risk assessment approach results in a marked increase in the estimated economic benefits of reducing each ton of PM2.5 emissions versus historical methodologies. As the American Chemistry Council discusses at length in their comments on the proposed NESHAP from the Portland Cement Manufacturing Industry, [Footnote: EPA-HQ-OAR-2002-0051-2849.2, posted 9/8/09]

EPA has not provided scientific justification for its proposed approach of extrapolating PM mortality risks to the lowest modeled ambient levels. An examination of the expert group advice cited by EPA in support of this approach reveals mostly the opposite, i.e., preference for the use of a threshold or apparent threshold for PM risk assessment. A critical review of the published literature also fails to provide support for EPA‘s new method for PM risk assessment. Many of the published studies cite evidence for nonlinearity and thresholds. Therefore, we do not believe that EPA‘s new approach to extrapolate mortality risks attributed to exposure to ambient PM linearly to the lowest modeled levels is or can be scientifically supported.

In addition, the benefit per ton approach used by EPA in this RIA does not consider changes in population exposure or baseline health rates and therefore does not conform to EPA guidelines for performing RIAs. EPA has not considered the full range of concentration response functions for chronic mortality which if used would significantly lower the range of benefits estimates. EPA has inappropriately used opinions of selected experts as a substitute for data in their economic analysis. Finally, EPA has used an inaccurate metric to derive estimates of the economic value of reduced chronic mortality.

As a result, the alleged health benefits attributed to reductions in exposure to PM2.5 and their estimated economic impact claimed in this rulemaking fail because they are built on a faulty foundation.

Recommendation: Re-evaluate the claimed health benefits for the estimated PM2.5 reductions attributed to this proposal using the traditional and scientifically validated threshold or apparent threshold approach.

Response: The weight of scientific evidence strongly supports modeling PM-related mortality and morbidity by using concentration-response functions that do not incorporate an assumed threshold. In 2009, the final Integrated Science Assessment for Particulate Matter indicated that "[o]verall, the studies evaluated further support the use of a no-threshold log-linear model…" (U.S. EPA, 2009). In 2010, the Health Effects Subcommittee of the Science Advisory Board "fully supports EPA's decision to use a no-threshold model to estimate mortality reductions. This decision is supported by the data, which are quite consistent in showing effects down to the lowest measured levels. Analyses of cohorts using data from more recent years, during which time PM concentrations have fallen, continue to report strong associations with mortality. Therefore, there is no evidence to support a truncation of the CRF" (EPA-SAB-COUNCIL- 10-001). Our approach to estimating PM-related health impacts is consistent with the key findings in these reports. In addition, our approach is consistent with the on-going PM NAAQS review.

In conjunction with the commenter's concern and consistent with recent scientific advice, we have replaced the previous threshold sensitivity analysis with a new "lowest measured level" (LML) assessment. While an LML assessment provides some insight into the level of uncertainty in the estimated PM mortality benefits, EPA does not view the LML as a threshold and continues to quantify the PM-related mortality impacts using the full range of modeled air quality concentrations.

Comment: Develop cost and benefit analyses on a source subcategory basis. EPA has evaluated this proposal on a total source category basis, primarily by taking credit for presumably large PM reductions from certain solid fuel categories. This approach hides the fact that there are essentially no HAP, PM or other emission reductions associated with the gas subcategories to justify the proposal or even the imposition of a technology standard.

Response: In the regulatory impact analysis (RIA), we provide pie charts to illustrate the fraction of benefits by subcategory, including the fraction associated with gas boilers.

Comment: OTC advises EPA in developing the final rule that the Agency needs to be sensitive to the impact of the boiler MACT on other pollutants, specifically nitrogen oxides (NOx) and sulfur dioxides (SO2). The proposed boiler MACT appropriately focuses on hazardous air pollutants (HAPs), and not on these two criteria pollutants. However, Industrial, Commercial and Institutional (ICI) boilers emit significant amounts of NOx, which are a component of ozone and particulate pollution, and SO2, also a component of particulate pollution. These compounds reduce lung function, aggravate asthma and other respiratory illnesses, and contribute to premature death. NOx and SO2 emissions are also components of acid rain pollution, which damages forests and erodes structures. These pollutants further damage the environment through eutrophication of waterways, which contaminates water and affects plant and animal health, and reduction in visibility in parks and wilderness areas. EPA should ensure that compliance with the boiler MACT does not result in increasing emissions of NOx and SO2 into the environment.

Response: In the regulatory impact analysis, we account for the emission disbenefits to the extent feasible.

Comment: EPA's benefit per ton approach does not conform with it's own Guidelines for Performing RIAs

According to EPA, due to analytical limitations, they did not provide a comprehensive risk-based approach to evaluate PM2.5 related benefits. Rather, EPA used the "benefit-per-ton" approach. With this approach, EPA provides no estimate of the changes in population exposure that will result from implementation of this rule. Furthermore, the benefit-per-ton approach does not considerer local variability in population density, meteorology, baseline health incidence rates, or other local factors that will certainly influence the risk estimates. Since many of these factors are mentioned as key factors to include in the EPA Guidelines for Performing an RIA, the RIA does not conform to EPA's own guidelines for performing an RIA.

Response: For the final major source rule, EPA has provided a more comprehensive benefits analysis that includes sector-specific air quality modeling and benefits modeling. The methodology used for the proposal analysis for estimating the health benefits associated with reducing PM2.5 and precursor emissions is based on peer-reviewed publications (see Fann, Fulcher, and Hubbell, 2009). Even though national average benefit-per-ton estimates are inherently more uncertain than sector-specific modeling, EPA has high confidence in the magnitude of total monetized benefits at the national level, but the benefits for specific locations may vary.

Comment: Since chronic mortality accounts for over 90 percent of the benefits of PM2.5 benefits reductions, the concentration response function (CRF) used for this health endpoint is critical. As mentioned above, EPA's upper and lower range of benefits are derived using mortality estimates from Pope et al. and Laden et al. EPA provides no clear rationale for using these single point values from two chronic air pollution studies. Other CRFs are available from these same studies as well as those from many other peer reviewed studies from the U.S. and other regions (e.g. Krewski et al. 2000; Enstrom, 2005; Beelen et al. 2008). Since the majority of the CRFs not considered by EPA indicate a lower range of mortality risks, and some even report no statistically significant association between exposure to fine PM and chronic mortality, the approach used by EPA results in an upper bias in risks and benefits.

There are many serious scientific concerns with the study by Laden et al. (2006) which EPA uses to support their upper bound mortality estimates. These concerns, which should disqualify this study for use in risk assessment, are discussed in detail in the American Chemistry Council comments on EPA's new methodology to estimate the benefits of PM reductions (ACC, 2009). For example, the results are not based on actual PM2.5 exposures since PM2.5 measurements were discontinued long ago in the six cities examined. The results are based on single pollutant models; confounding by other pollutants was not examined. In five of the six cities, the risk coefficients are not statistically significant.

In the RIA, EPA states that the CRFs they use from Pope et al. and Laden et al. were adjusted using multi-pollutant models (pg 6-3). This is incorrect. The CRF EPA used for chronic mortality from Pope et al and Laden et al were not adjusted for any other pollutant. In the case of Pope et al. 2002, EPA is using a version of the ACS study that did not evaluate confounding by other pollutants. In the 2000 reanalysis of ACS study reported by Krewski et al., results for PM2.5 in a two pollutant model with SO2 are available. However, EPA did not use these results. Krewski et al. reported that inclusion of SO2 dramatically decreased the chronic mortality attributed to PM2.5 to less than 2 percent per 10 ug/m3 and the results were no longer statistically significant. In the case of Laden et al., as mentioned above, multi-pollutant models were not used. Thus, for both studies, EPA is assigning the entire impact of reductions in air pollution to a single pollutant, PM2.5. Since EPA claims all of these other pollutants potentially also cause mortality and morbidity, EPA is double and triple counting the benefits of air pollution reduction.

Response: The choice of studies used to estimate the relationship between PM2.5 and premature mortality has been extensively reviewed and supported by EPA's Science Advisory Board, and the rationale for using both the Pope et al. (2002) and Laden et al. (2006) studies is explained in the regulatory impact analysis.

Comment: Biomass plants release tons of particle pollution, this is no secret, it says so in their applications.
According to the American Heart Association, there is no safe threshold for particle pollution, in other words, there is no safe level or number. The AHA states that the National Ambient Air

Quality Standards (NAAQS) standards are not stringent enough to protect our health. There is a linear relationship between the amount of air pollution and the amount of heart attacks and death, not only from heart disease but from ALL CAUSES. In other words, the higher the level of particle pollution, the higher the death rate and the only safe level is zero.

In a Nov 16 2009 letter from Scott Keays of the American Lung Association to Sen. Kerry here are some of the specific wordings: "Burning wood, like burning any other substance, releases toxic chemicals and particles which can negatively affect both the environment and respiratory health". "Biomass and diesel emissions are particularly harmful." "The concerns about generating electricity through biomass become even more troubling when you consider how wasteful and inefficient this source of power is." “Given the technology and the natural resources available to us, we do not believe that anyone should be forced to choose between electric power and their health".

In a Feb 4 2010 statement, the Physicians for Social Responsibility stated "If the proposed biomass power plants are built in the Pioneer Valley, the resulting excess air pollution would exacerbate an already unacceptable public health burden."

The Massachusetts Medical Society and the Florida Medical Association, worried about the health impacts of biomass plants, have also come out with statements against them.
In recognition of the numerous and serious adverse health consequences that can result from human exposure to the components of emissions of biomass burning, the North Carolina Academy of Family Physicians (NCAFP) has issued a letter of concern regarding the development of biomass burning plants in the State of North Carolina on April 19, 2010.

In short, the hazardous health impacts including death, disease and cancer is well known and acknowledged by the medical community; physician groups and medical associations representing tens of thousands of doctors across the U.S. have weighed in against the deadly impacts of biomass plants. The media will likely link any further decisions to approve biomass plants with those specific government officials that gave the approval, this could be a "career - ender".

Response: EPA agrees that exposure to fine particulates and toxic air pollutants is associated with severe health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment: EPA indiscriminately applies to CRF for PM2.5 chronic mortality to all forms of PM including soluble sulfate PM which is a common form of PM predicted to be reduced by this rule. EPA ignores scientific evidence that suggests that sulfate aerosols exhibit a lower toxic potential than other forms of PM (Schlesinger et al. 2003). First, soluble forms of PM such as nitrate, sulfate, and ammonium PM exhibit much lower toxicity potential than carbonaceous PM (soot) with high metal content. Further, soluble PM distributes in the upper respiratory tract and is less likely to produce systemic toxic effects (e.g. chronic mortality) than non-water soluble fine PM that distribute in the lower respiratory tract. In particular, there is an extensive toxicology database that indicates that sulfate PM presents low toxicity potential. EPA's "onesize-fits-all" approach results in over-estimating the risks of emissions from this rule, since a large portion of PM EPA predicts from boiler emissions is water soluble secondary sulfate PM.

Response: In the regulatory impact analysis, EPA clearly notes that the benefits models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because there is no clear scientific evidence that would support the development of differential effects estimates by particle type.

Comment: The justification for the action is admirable, but short-sighted, as the detrimental effect of the loss of work and the decrease in quality of life caused by this action will more than offset the few lives and discomforts the proponents enumerate as justification AND ACTUALLY COST LIVES! One would have to believe, based on the justification, that most of these solid-fuel-burning sources are all placed in urban settings, in reality, most are in rural, low-population areas. It has been widely discussed, researched and proven that UNEMPLOYMENT causes far more deaths, drug use, domestic violence, smoking, dependency, etc than this list. So, it will have the opposite effect than that they hope to achieve. According to the CDC reports that the deaths per 100,000 rose from an all-time low of 760 in 2007 to 838 in 2009 due to the economic downturn, essentially unemployment. That is an increase of 234,000. This occurred even as the emissions from boilers were decreased by a large percentage due also to the economic downturn. I believe this correlationessentially negates the justification and exposes the projection of mortality improvements as a myopic grasp that ends up being a rounding error. This is certain.

Response: Based on the conclusions of EPA's Integrated Science Assessment on Particulate Matter (U.S. EPA, 2009), long term exposure to fine particles has a causal link to premature mortality, even at low ambient levels. In addition, exposure to fine particles is associated with cardiovascular and respiratory health effects. The methodology for estimating the health benefits associated with reducing PM2.5 and precursor emissions is based on peer-reviewed publications (see Fann, Fulcher, and Hubbell, 2009).

Comment: EPA has inappropriately applied a linear no threshold approach to assess all forms of PM

EPA uses a linear no threshold approach to assess mortality. This approach results in a significant (3-10 fold) increase in estimated mortality versus a more logical approach that assumes the existence of an effects threshold. While the threshold approach has become the default that EPA uses for all risk assessments of ambient PM, the linear no threshold approach for sulfate PM is not supported by the actual underlying epidemiology data.

In a re-analysis of the original ACS-Pope study, the authors examined the concentration response relationship for sulfate PM and concluded that there is a threshold for chronic mortality near the concentration of 12 µg/m3.(Abrahamowicz et al. 2003, Krewski et al 2000). Since in most locations of the U.S., sulfate PM levels are already below this level, further reductions are expected to produce no change in chronic mortality.

Response: The weight of scientific evidence strongly supports modeling PM-related mortality and morbidity by using concentration-response functions that do not incorporate an assumed threshold. In 2009, the final Integrated Science Assessment for Particulate Matter indicated that "[o]verall, the studies evaluated further support the use of a no-threshold log-linear model…" (U.S. EPA, 2009). In 2010, the Health Effects Subcommittee of the Science Advisory Board "fully supports EPA's decision to use a no-threshold model to estimate mortality reductions. This decision is supported by the data, which are quite consistent in showing effects down to the lowest measured levels. Analyses of cohorts using data from more recent years, during which time PM concentrations have fallen, continue to report strong associations with mortality. Therefore, there is no evidence to support a truncation of the CRF" (EPA-SAB-COUNCIL- 10-001). Our approach to estimating PM-related health impacts is consistent with the key findings in these reports. In addition, our approach is consistent with the on-going PM NAAQS review.

In conjunction with the commenter's concern and consistent with recent scientific advice, we have replaced the previous threshold sensitivity analysis with a new "lowest measured level" (LML) assessment. While an LML assessment provides some insight into the level of uncertainty in the estimated PM mortality benefits, EPA does not view the LML as a threshold and continues to quantify the PM-related mortality impacts using the full range of modeled air quality concentrations.

Comment: EPA used an inaccurate metric to value chronic mortality

Presenting estimates of premature or additional deaths related to air pollution is the default approach used by EPA. However, as noted by Rabl (2006), estimating the number of premature deaths due to air pollution is the most accurate metric.

First, it makes little sense to add the number of deaths independently due to different contributing causes, such as air pollution, smoking or lack of exercise because doing so could result in a number far in excess of total mortality. When individual air pollutants are considered without adequately adjusting for other pollutants, this may lead to double counting of deaths in the analysis.

Second, the number of deaths fails to take into account the magnitude of the loss of life expectancy per death, which is very different between, for example, air pollution deaths, typically occurring in older people, and traffic accidents, typically occurring in younger people.

Third, in contrast to the primary causes of deaths for example heart disease and cancer, with ecologic air pollution studies, it is not possible to accurately estimate the total number of premature deaths attributable to air pollution. The reason is that ecologic air pollution studies provide population-based "years of life lost", but not individual years of life lost per death. Therefore, it is not known if a few individuals lose a number of years of life, or if many individuals lose only a few months.

For these reasons, Rabl et al. (2003, 2006) and others have suggested expressing air pollution mortality in terms of "Loss of Life Expectancy" (LLE) changes or value of a life year (VOLY). This framework automatically takes into account the constraint that everybody dies exactly once, regardless of their exposure or lack thereof, to air pollution. The VOLY approach was recognized by the European Union (EU) as providing a more accurate and meaningful metric to quantify potential chronic effects of air pollution, and this approach was used to evaluate various policy options for reducing PM air pollution under the EU Clean Air for Europe program.

Response: EPA continues work to update its guidance on valuing mortality risk reductions, which is currently referred to as the value of a statistical life (VSL). The Agency determined that a single, peer-reviewed estimate applied consistently best reflects the advice it has received from the Science Advisory Board while the Agency continues its efforts to update its guidance on this issue. This VSL is $6.3 million (2000$), which was calculated as the mean VSL across 26 studies. The Agency is committed to using scientifically sound, appropriately reviewed evidence in valuing mortality risk reductions and has made significant progress in responding to the Science Advisory Board's specific recommendations.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.2

Comment Excerpt Number: 7

Comment: To develop their figures of societal benefits of $17-41 and $15-37 billion per year, EPA used a figure of $8.9 million for the value of a statistical life (VSL). This figure was derived from U.S.-based studies of willingness to pay and contingent valuation and the results therefore reflect socioeconomic preferences expressed by the U.S. population. There are vast differences in results of such studies based on socioeconomic differences. Furthermore, the willingness to pay/contingent valuation studies used to support the above figure were not specific to the assessment of air pollution. Rather, most of these studies were based on accidental deaths, with most deaths occurring at younger ages (30-40 years) than expected to results from air pollution.

Recently, a study to evaluate the monetary valuation of mortality and morbidity risk from air pollution, conducted under the EU Sixth Framework Programme, has been published (NEEDs, 2007). The objective of the study was to provide more reliable and credible estimates of the VOLY lost by air pollution mortality. For the EU 16 and New Member Countries, figures of 40,000 Euro and 25,000 Euro, respectively, were recommended. These values were based on use of mean figures. Using median values, which minimizes the impact of extreme values, figures of 19,000 and 15,000 Euro, respectively, were reported. These figures highlight the extreme nature of the $6.3 million VSL value used by EPA. We encourage EPA to conduct a similar study for the U.S. and replace the currently used VSL with a more accurate VOLY metric derived from willingness to pay for studies specific for air pollution. The exaggerated VSL figure EPA currently uses significantly contributes to a dramatic over-estimate of the economic benefits of reducing air pollution. Even the most conservative estimates of the life years lost from chronic exposure to air pollution are on the order of a few years.

Similarly, the World Health Organization (WHO) uses the quality adjusted life year (QALY) approach, rather than the VSL approach, to assess the impact of air pollution on mortality. The NEEDs study recommends QALY values on the order of 50,000 Euro. Again, using this approach, much lower figures of economic benefits of reduced boiler emissions of PM would be realized.

Response: EPA continues work to update its guidance on valuing mortality risk reductions, which is currently referred to as the value of a statistical life (VSL). The Agency determined that a single, peer-reviewed estimate applied consistently best reflects the advice it has received from the Science Advisory Board while the Agency continues its efforts to update its guidance on this issue. This VSL is $6.3 million (2000$), which was calculated as the mean VSL across 26 studies. The Agency is committed to using scientifically sound, appropriately reviewed evidence in valuing mortality risk reductions and has made significant progress in responding to the Science Advisory Board's specific recommendations.

Comment Excerpt Number: 7

Comment: EPA argues that the large costs of this rule are justified by the co-benefits of PM reductions. Ironically, suggested add-on controls for gas-fired sources for PM would actually cause PM to increase. In fact, PM emissions from gas-fired units are so inherently low as to require established measurement techniques to be modified by significantly extending routine testing periods in an attempt to recover enough material to quantify emissions.

Response: In the regulatory impact analysis, we account for the emission disbenefits to the extent feasible.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.2
Comment Excerpt Number: 8

Comment: EPA is inappropriately using reductions of PM2.5 to justify a myriad of regulations whose primary focus is not on control of PM2.5.

Table 1 of the submittal provides a partial list of the regulations and proposed regulations where EPA has included reductions in PM2.5 in the corresponding RIA. Even though most of the regulations do not focus on regulation of PM2.5 but rather other NAAQS pollutants and HAPs, the vast majority of the total economic benefits (88-91 percent) are due to reductions of PM2.5. In our view, the total monetary benefit that EPA estimates from these reductions in PM2.5, which is on the order of $300-450 billion, is not realistic.

Table 2 of the submittal provides a partial list of the health benefits that EPA has estimated due to implementation of selected regulations and reductions in PM2.5. Again, in our view, the overall total estimates are not realistic.

Response: In many instances, it is not possible to quantify and monetize all of the benefits associated with a regulatory action due to data, resource, and methodological limitations. For this rule, we were only able to monetize the benefits associated with reducing exposure to PM2.5 as a result of reducing direct PM2.5 emission and PM2.5 precursor emissions such as SO2. If we were able to fully monetize all of the benefit categories, the benefits would exceed the costs by an even greater amount than we currently estimate.

EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. Co-benefits that occur as a result of a regulatory action are appropriate to include in the RIA, and it is appropriate to compare the total monetized benefits with the costs.

EPA anticipates PM and SO2 emission reductions as a result of this rule, and the benefits associated with these emission reductions are appropriate to include in this RIA. These emission reductions would occur regardless of an area's attainment status under the NAAQS, but these emission reductions might help those areas that are in non-attainment to reach attainment.

Commenter Affiliation: Ameren Services
Document Control Number: EPA-HQ-OAR-2002-0058-2803.1
Comment Excerpt Number: 32

Comment: Ameren believes the benefits analysis conducted for the proposed rule is flawed and overestimates the changes in ambient levels of PM2.5 used to estimate the monetized benefits of the rule.
The use of the Fann et al. (2009) methodology to estimate reduction in ambient levels of PM2.5 is improper. The Fann et al. methodology has not undergone a rigorous peer review as should be required for any methodology utilized by US EPA for estimating the effects of a regulatory scheme on the health of the US population. The Fann, et al. methodology uses a flawed emission inventory (US EPA's 2001 National Emissions Inventory) and projects that inventory out to 2015. The 2001 inventory has been replaced with a newer inventory which should have been utilized. Because Fann does not include the revised inventory in the open sourced study, it is impossible to see how Fann projected emissions out to 2015. He only makes a vague statement that the projected inventory includes several federal regulatory programs such as CAIR.

Fann utilizes the CMAQ version 4.4 regional air quality model to estimate PM2.5 ambient air quality levels associated with various regulatory schemes. The CMAQ version 4.4 model has several flaws which render it's use to estimate PM2.5 levels inappropriate without a comparison to actual PM2.5 levels in modeled areas. This version of CMAQ significantly overestimates PM2.5 levels when compared to actual measured PM2.5 levels. Because CMAQ overestimates PM2.5, several updates to this model have been made to correct these known deficiencies. Despite these known problems, Fann et al. make no effort to correct for this overestimation or make any comparison to actual measured PM2.5 levels. Consequently, it can be presumed that the model as used by Fann, overestimates PM2.5 ambient air quality levels resulting from each ton of direct PM2.5 and PM2.5 precursors. This will necessarily result in an overestimation of the change in PM2.5 level resulting from the reduction of each ton of direct PM2.5 and PM2.5 precursors. Similarly, by overestimating the change in PM2.5 ambient air quality levels, the Fann et al. methodology also overestimates the benefits of the associated reductions.

US EPA should not utilize outdated versions of regional air quality models which over estimate impacts when analyzing the economic impacts associated with the proposed regulations. US EPA should revise this analysis to properly account for the deficiencies of the Fann methodology and the associated inventory and regional air quality model.

Response: For the final major source rule, EPA has provided a more comprehensive benefits analysis that includes sector-specific air quality modeling and benefits modeling. The methodology used for the proposal analysis for estimating the health benefits associated with reducing PM2.5 and precursor emissions is based on peer-reviewed publications (see Fann, Fulcher, and Hubbell, 2009). Even though national average benefit-per-ton estimates are inherently more uncertain than sector-specific modeling, EPA has high confidence in the magnitude of total monetized benefits at the national level, but the benefits for specific locations may vary.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 75

Comment: The particulate matter health benefits assessment in the Regulatory Impact Analysis (RIA) was not determined correctly and should be reevaluated.

EPA attributes all of the economic benefits in the RIA to reductions in particulate matter, a criteria pollutant. EPA was unable to quantify the benefits of any HAP reductions that might be achieved by the proposed rule. It is questionable for EPA to justify a regulation focused on HAP reductions on the basis of reductions in criteria pollutants. The Clean Air Act provides different authorities and different procedures for addressing criteria pollutants and HAPs. Congress established separate regulatory programs to address these very different types of pollutants and to minimize the disruption to the economy by applying specifically designed approaches to each. Furthermore, EPA has already claimed the benefits associated with PM under the NAAQS rulemakings and procedures. By claiming these benefits again under HAP reductions, EPA is double-counting the benefits of PM reductions. This is part of a wider trend whereby EPA is inappropriately using “co-benefits” of PM reductions to justify a myriad of regulatory actions that focus on pollutants other than PM.

As described in the detailed comments included in Attachment 1, the methodology EPA used to quantify the benefits of reducing PM emissions is not scientifically sound and significantly over-estimates the benefits. The key concerns are: 1) EPA’s benefit per ton approach does not consider changes in population exposure or baseline health rates and does no conform with it’s own guidelines for performing RIAs; 2) EPA has not considered the full range of concentration response functions for chronic mortality; 3) EPA has inappropriately applied a linear no threshold approach to assess all forms of PM and extrapolated mortality far beyond the data in the underlying studies and below background levels; 4) EPA has inappropriately used opinions of selected experts as a substitute for data in an economic analysis and ; 5) EPA has used an inaccurate metric to value chronic mortality. When taken in total and when compared to background causes of disease and mortality, the overall benefits EPA is claiming from PM reductions are unrealistic.

EPA should reevaluate the particulate matter benefits claimed as described below:

Determine the health benefits of hazardous air pollutant (HAP) reductions associated with the proposed rule; this is a HAP rule, not a criteria pollutant rule.

Reevaluate the claimed health benefits using a more scientifically sound basis for the estimated particulate reductions.

Response: In many instances, it is not possible to quantify and monetize all of the benefits associated with a regulatory action due to data, resource, and methodological limitations. For this rule, we were only able to monetize the benefits associated with reducing exposure to PM2.5 as a result of reducing direct PM2.5 emission and PM2.5 precursor emissions such as SO2. If we were able to fully monetize all of the benefit categories, the benefits would exceed the costs by an even greater amount than we currently estimate.

EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. Co-benefits that occur as a result of a regulatory action are appropriate to include in the RIA, and it is appropriate to compare the total monetized benefits with the costs.

EPA anticipates PM and SO2 emission reductions as a result of this rule, and the benefits associated with these emission reductions are appropriate to include in this RIA. These emission reductions would occur regardless of an area’s attainment status under the NAAQS, but these emission reductions might help those areas that are in non-attainment to reach attainment.

Comment: More Stringent Standards Are Likely Required to Maximize Net Benefits
If more stringent standards did not increase social welfare, EPA would be justified in solely using the "MACT floor" emission standards, as determined by Section 112(d)(3). But the figures presented in the EPA's regulatory impact analysis ("RIA") indicate that this may not be the case. High ratios of benefits to costs may indicate under-regulation. Figure 1 shows a graphical depiction of the marginal costs and benefits of a hypothetical optimized regulation, where the stringency of the regulation has been set to equalize marginal costs and marginal benefits. Area A (the area underneath the marginal cost curve) represents the total social costs of the regulation. The combination of Areas A, B, and C (the total area underneath the marginal benefit curve) represents the total social benefits of the regulation. In this simple linear example, this gives a ratio of 3:1 for total benefits to total costs.

[See submittal for Figure 1. Depiction of Hypothetical Optimized Regulation]

By contrast, Figure 2 shows a graphical depiction of the marginal costs and benefits of a hypothetical scenario of under-regulation, where marginal costs have been set well below marginal benefits. Area D (the area underneath the marginal cost curve) represents the total social costs of the regulation. The combination of Areas D, E, and F (the total area underneath the marginal benefit curve) represents the total social benefits of the regulation. In this example, the ratio of total benefits to total costs is 7:1.

[See submittal for Figure 2. Depiction of Hypothetical Under-Regulation]

These twin examples show how under-regulation leads to a higher ratio of total benefits to total costs.
Table 1 shows the costs and benefits of the Major Source Proposal and Area Source Proposal at a discount rate of 7%. [Footnote: Note that choosing the higher discount rate minimizes the ratio in this case.]

[See submittal for Table 1. Total Costs and Benefits of Proposed Major and Area Source Rules at 7% Discount Rate (Millions of 2008$)]

Given the range of benefit estimates, the ratio of benefits to costs is between 5 and 13 for the Major Source Proposal and between 1.8 and 4.4 for the Area Source Proposal. As demonstrated by the simple example above, this may indicate that the agency is under-regulating in at least the Major Source Proposal. The RIA also excludes many highly significant benefits categories that the agency did not have the time or analytical ability to quantify. [Footnote: For example, the RIA concentrates on the health effects related to particulate matter reductions, and "[t]he benefits from reducing hazardous air pollutants have not been monetized in this analysis, including reducing 370,000 tons of carbon monoxide, 37,000 tons of HCl, 1,000 tons of HF, 8.3 tons of mercury, 3,400 tons of other metals, and 1,200 grams of dioxins/furans each year." RESEARCH TRIANGLE INSTITUTE, RTI PROJECT NUMBER 0209897.004.074, REGULATORY IMPACT ANALYSIS: NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR

POLLUTANTS FOR INDUSTRIAL, COMMERCIAL, AND INSTITUTIONAL BOILERS AND PROCESS HEATERS at 6-1 (Draft Report, Prepared for EPA, Apr. 2010) [hereinafter RIA].] This means that the true benefit-to-cost ratios are almost certainly higher than those indicated by the table.

While the RIA indicates that there are no additional benefits from regulating major sources with heat input capacity under 10 MMBtu/hr, [Footnote: For example, the RIA concentrates on the health effects related to particulate matter reductions, and "[t]he benefits from reducing hazardous air pollutants have not been monetized in this analysis, including reducing 370,000 tons of carbon monoxide, 37,000 tons of HCl, 1,000 tons of HF, 8.3 tons of mercury, 3,400 tons of other metals, and 1,200 grams of dioxins/furans each year." RESEARCH TRIANGLE INSTITUTE, RTI PROJECT NUMBER 0209897.004.074, REGULATORY IMPACT ANALYSIS: NATIONAL EMISSION STANDARDS FOR HAZARDOUS AIR POLLUTANTS FOR INDUSTRIAL, COMMERCIAL, AND INSTITUTIONAL BOILERS AND PROCESS HEATERS at 6-1 (Draft Report, Prepared for EPA, Apr. 2010) [hereinafter RIA] at 6-31.] this does not show that the costs of additional emissions standards on sources with heat input capacity over 10 MMBtu/hr are higher than the benefits. EPA should analyze whether alternative regulatory structures—in light of all quantified and unquantified benefits—would better maximize net benefits.

Response: In conjunction with all of the comments received on the proposal, EPA has re-evaluated the options. See the Regulatory Impact Analysis for the analysis of the options for the final rule.

With regard to the regulatory options selected, EPA conducted a beyond-the-floor analysis as required under the CAA and selected one beyond-the-floor standards, the energy assessment, as a cost-effective option for reducing HAP emissions from industrial, commercial, and institutional boilers and process heaters.

Comment: The limits are so unreasonable that the impact analysis in the rule assumes that no new biomass boilers will ever be built at major sources. This is absurd, given the fact that biomass is greenhouse gas-neutral and the government is pushing increased use of renewable energy.

Response: It is necessary to note that the limits were not a factor in projecting the number of new major source biomass units. Rather, projections were based on the economic outlook of the biomass energy sector and the applicability of the Utility NESHAP and area source boiler rule. The EPA recognizes ongoing projects and funding supporting biomass as a form of renewable energy and new biomass boilers would be built, but EPA does not expect this growth to fall under the major source category. Please see the response to comment EPA-HQ-OAR-2002-0058-2805.1, excerpt 1 for details on the projection analysis.

Comment: The Regulatory Impact Analysis report projects no costs for new biomass or coal units, based on Department of Energy projections. Given the forest products industry's move away from fossil fuel firing and toward biomass, the many state programs mandating renewable energy portfolio standards, our knowledge of several biomass boiler projects under development or consideration, and the trend toward bio-based fuels and bio-based materials production, we do not believe that there will be no new biomass projects in the next few years (unless the new source standards remain so stringent that boiler manufacturers are unable to guarantee compliance with the new source emission limits, as indicated in the Metso comments included in Appendix F). In addition, boilers in many industries are aging and it may not be feasible or cost effective to retrofit these boilers to comply with the rule, necessitating construction of replacement boilers if the facility economics remain viable such that the facility is not closed.

EPA should re-evaluate this component of the RIA and include projected costs for new solid-fuel boilers.

Response: See the response to EPA-HQ-OAR-2002-0058-2805.1, excerpt 1 regarding biomass plants in development and the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 148 regarding the replacement of older boilers.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 220

Comment: In 2003 and in the current rulemaking, the estimate of the number of new sources was derived from Department of Energy projections on fuel expenditures. The vast differences between the two estimates are unexplained. However, at a minimum this approach fails to account for the large number of new units that will have to be constructed to replace existing units because the existing units cannot comply with this rule. Constructing a replacement unit, rather than adding controls to an existing unit adds significant costs and burdens because the new unit is presumably subject to the new source requirements rather than the existing source requirements and because an entire new boiler and process heater must be constructed, not just some incremental facilities. As we discuss in comment 1 above, we think replacement of boilers and process heaters will be prevalent because the existing units cannot be retrofitted with the required controls due to space and structural concerns.

Recommendation: Reconcile the 2003 and 2008 estimates of new units.
Recommendation: Adjust the new unit estimate for the need to replace many existing units in order to try to meet the proposal requirements for existing units.

Response: The reason for the difference in projections for new major source boilers between the vacated boiler rule and the proposed rule are attributable to the economic climate and energy demand projected by the Department of Energy Annual Energy Outlook at the time of the vacated standard and today. When the projections for the vacated rule were calculated the economic growth rate was much higher and in turn there were larger estimates for fuel and energy use. Compare that to now where the economy is more stagnant and energy consumption growth rates are flat. The method of estimating new units was the same for the vacated 2004 rule and the 2008 proposal, but the inputs to the methodology were different. Projecting the numbers of boilers which would replace their older units due to space and structural concerns, and making an estimate based on reasonable assumptions would require additional data which the EPA does not have. No specific details were provided by the commenters to support their recommendation.

Comment: The proposed rule concludes that no new biomass boilers will ever be constructed at major sources in the United States as a result of the stringency of the rules. Given the government's push for the use of renewable energy, this outcome would be absurd. A greenhouse-gas-neutral fuel would be turned into a waste which would degrade into methane gas creating 21 times the global warming potential when compared to its combustion as fuel. Solar and wind are not reliable renewable energy sources in the southeastern United States, so biomass provides the only viable option for renewable energy in this part of the country.

Comment: Projections for Increase in Biomass to Energy Generation.
EPA's projections of biomass buildout, as reflected in the cost estimate portion of the Major Source rule, appear to rely on an April 2010 memo from ERG where ERG actually projects a decline in biomass power generation by 2015. [Memo from Graham Gibson, ERG to Jim Eddinger, EPA. New Unit Analysis Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source. April, 2010]. EPA seems incognizant of the actual number of biomass plants and biomass co-firing projects currently proposed and in permitting, or the amount of biomass power that the Energy Information Administration projects will come online under both business-as-usual scenarios and scenarios where renewable energy is promoted at the federal level. 2[Environmental Working Group, 2010. Clear Cut Disaster. Washington, DC.]. According to industry data, current proposals for biomass power will virtually double the existing capacity for electric generation from biomass, adding an additional 5830 MW, which may be a conservative estimate given increased number of co-firing applications. Current estimates for pending applications in Ohio range from 1200-1600 MW, permit applications. [EL-REN applications approved and pending before the Public Utilites Commission of Ohio July 30,2010.http://www.puco.ohio.gov] Combined permits for Florida and Georgia are roughly an additional 1200 M W. With the amount of biomass power due to come online in the next five years, it is significant that in many respects, the MACT standards proposed for biomass boilers are not as stringent as those proposed for coal-fired boilers.

Response: With regard to the referenced Environmental Working Group document, it does reference 118 new biomass power plant proposals; however, information on size of the boilers and how many are co-fired versus dedicated biomass plants is not provided. For the Ohio, Florida, and Georgia permits cited in the comment, details on if the units are co-fired or dedicated biomass is also not provided. This information is important because the referenced co-fired boilers could fall under the Utility NESHAP rule or be classified as either an area or major source under the Boiler NESHAP. Without details an estimate for applicable new major source biomass boilers is difficult.

EPA conducted additional research into biomass projections using data from the Energy Information Administration's (EIA) April 2009 report An Updated Annual Energy Outlook 2009 Reference Case Reflecting Provisions of the American Recovery and Reinvestment Act (ARRA) and Recent Changes in Economic Outlook and The Handbook of Biomass Combustion and Co-Firing published in 2008. Three sectors for biomass use are provided; commercial biomass, industrial biomass, and electric power (dedicated and co-fired biomass). Projections for 2008 to 2013 are flat for commercial biomass and show a slight decrease for industrial biomass. Within the electric power sector the projections show an increase in growth for both dedicated and co-fired biomass plants. Many co-fired plants in the electric power sector would be covered under the Utility boiler NESHAP. For dedicated biomass plants, based on data received during the comment period these biomass boilers would be classified as area sources of HAP. Comparing the projections for growth of dedicated biomass plants in the EIA report (.08 quadrillion Btu/yr) versus the area source new unit projection analysis for the boiler rule (.06 quadrillion Btu/yr) shows that projecting only new area source boilers is realistic. The methodology for projecting new boilers is discussed in further detail in the memorandum "Revised New Unit Analysis Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source (2011".

With regard to the limits of biomass boilers versus coal boilers, the EPA thanks the commenter for their concern but has based the MACT limits off the data available for each subcategory.

Comment: As shown in Tables 10 and 11 (75 FR at 32037 and 32038), EPA has estimated the cost of compliance and the environmental benefits for new biomass units and coal units to be zero as listed in Table 11. This implies EPA does not believe there will be any new major biomass or coal plants built or reconstructed. We are aware of several biomass power plants in the development phase, which may or may not be major HAP sources. Certainly, even smaller biomass boiler projects may occur at existing major HAP sources. Federal energy policy encourages the use of renewable energy and several studies show biomass being a significant portion of new renewable energy sources. Therefore the costs cannot be zero going forward, and neither can the environmental benefits of biomass, which include emission offsets from fossil fuels, including greenhouse gases.

Response: See the response to EPA-HQ-OAR-2002-0058-2805.1, excerpt 1 regarding biomass plants in development and the response to comment EPA-HQ-OAR-2002-0058-1597.1, excerpt 5 regarding biomass projections from a renewable energy perspective.

Comment Excerpt Number: 148

Comment: The RIA report projects no costs for new biomass or coal units, based on Department of Energy (DOE) projections. However, there are a number of reasons why DOE and EPA projections are wrong. Given the many state programs mandating renewable energy portfolio standards, we do not believe that there will be no new biomass projects in the next few years (unless the new source standards remain so stringent that boiler manufacturers are unable to guarantee compliance with the new source emission limits). In addition, the RIA failed to consider that solid-fuel boilers in many industries are aging and it may not be feasible or cost effective to retrofit these boilers to comply with the rule, necessitating construction of replacement boilers. EPA should re-evaluate this component of the RIA and include projected costs for new solid-fuel boilers.

Response: Looking in the near-term, it is difficult to project how many boiler operators would opt to construct a new boiler to replace their older one and estimate the associated costs. EPA’s analysis of new boilers is based on energy demand projections and estimates of boiler replacement rates due to age is outside the scope of this estimate. Furthermore, specific details were not provided by the commenter to incorporate into the estimate. Please see the response to comment EPA-HQ-OAR-2002-0058-2805.1, excerpt 1 for details on the projection analysis.

Commenter Affiliation: Missouri Fuels for Schools Project
Document Control Number: EPA-HQ-OAR-2002-0058-0847
Comment Excerpt Number: 1

Comment: The Missouri Fuels for Schools Project is funded through a $6 million ARRA grant from the Forest Service to help schools install and operate boiler systems that use woody biomass from local public and private land to heat and/or cool their facilities. This technology should help reduce dependence on fossil fuels, reduce energy costs, create or retain jobs and support healthy forests and the state's forest industry. Seven southern Missouri schools have been selected to have wood-chip heating systems, using efficient, low-emission boilers. Should there be requirements to have costly stack emission tests on a regular basis, there would be no savings to the schools and no reason to change from their existing fossil fuel heating systems. The EPA should instead focus on existing inefficient, polluting stoves. [See DCN:EPA-HQ-OAR-2002-0058-0847.1 for explanation of Missouri Fuels for Schools Project]

Response:

Commenter Name: Peter Maki
Commenter Affiliation: Missouri Fuels for Schools Project

Comment Excerpt Number: 1

Comment: The Missouri Department of Conservation (MDC), in cooperation with the USDA Forest Service's State& Private Forestry program, recently awarded almost $6 million in grants to seven public schools for "Fuels for Schools" projects. The grants are being funded through The American Recovery and Reinvestment Act (ARRA).

Grant recipients and amounts are:

Southern Reynolds R-II School District: $970,000

Perry County 32 School District: $970,000

Steelville R-III School District (Crawford County): $900,000

Rolla 31 School District Junior High Building (Phelps County): $760,000

Gainesville R-V School District (Ozark County): $970,000

Eminence R-I Elementary (Shannon County): $350,000

Mountain View-Birch Tree Liberty High School (Howell County): $850,000

“Fuels for Schools funds will help these schools and school districts install and operate boiler systems that use woody biomass from local and private forest land to heat and/or cool their facilities, “explained grant administrator John Tuttle, Forestry Field Programs supervisor for the MDC. “This technology should help reduce dependence on fossil fuels, reduce energy costs, create or retain jobs and support healthy forests and the state’s forest industry.”

The Fuels for Schools projects will help create a stronger market for woody material historically considered waste, such as unhealthy or small-diameter trees and wood debris left from logging,” he added. “These forest products currently have little or no commercial value so the Fuels for Schools projects can provide micro-markets for wood chips produced from them.” Tuttle explained that the projects also will support forest health, a key part of the MDC’s mission, by making it economical to thin overcrowded forest stands and remove diseased and insect-infested trees.

According to the Fuels for Schools and Beyond website (www.fuelsforschools.info), “In general, fuel cost savings for projects that have replaced natural gas boiler systems have averaged at 25% while facilities replacing fuel oil systems have enjoyed savings of 50-75%.”

What makes this technology so attractive to a school is the fuel cost savings the school will have in this era of tight budgets. The average fuel savings we calculate for the seven schools is 67%. A school such as Steelville, for example, will see its average fuel cost drop from $61,953 per year to $20,599 per year. Since the price of wood chips has been stable, unlike fossil fuel prices, there will be years when calculated savings will be more. Wood chips are our cheapest fuel at $3.25 per million BTU’s, compared to propane at $15.00 per million BTU’s, or electric heat at $25.00 per million BTU’s.

Other benefits of wood-chip heating systems, is that the technology we are using allows for over 80% burn efficiencies. These systems have minimal emissions compared to what the schools presently use. When wood biomass replaces fossil fuels, there is a net reduction in greenhouse gas emissions.

Comment: I want to bring to your attention the damage that your proposed rules regarding Boilers will have on our businesses. We employ over 125 people at each of our locations (2, soon to be 3) and these rules have the potential to shut us down and cause the loss of all those jobs. The cost to meet the unreasonable requirements in these rules may cause us to decide it is not worthwhile to operate. Do you realize these limits are unattainable and will cause no new biomass boilers to be built? The President’s has been promoting alternative energy to offset fossil fuels and we have been effectively using biomass in the forest products industry for years, these rules are a direct contradiction to the President's goals.

Comment Excerpt Number: 15

Comment: In stark contrast to the ICR cost estimates above, page 3-1 and 3-2 of the RIA (EPA-HQ-OAR-2002-0058-0810) indicates "The resulting total national cost impact of the proposed rule is 10.0 billion dollars in capital expenditures and 3.2 billion dollars per year in total annual costs. Considering estimated fuel savings resulting from work practice standards and combustion controls, the total annualized costs are reduced to 2.9 billion.

Using Department of Energy projections on fuel expenditures, the number of additional boilers that could be potentially constructed was estimated. The resulting total national cost impact of the proposed rule in the 3rd year is 17 million dollars in capital expenditures and 6.2 million dollars per year in total annual costs, when considering a 1 percent fuel savings.

Even the RIA estimate is significantly low for the following reasons (in addition to the significant underestimate of the number of sources discussed in Item 1).

There is no basis for the assumed 1% energy credit. Major sources already manage their energy use as a cost control measure and overlaying an Energy Star program on existing programs is unlikely to provide any benefits at major sources. Furthermore, all of the additional controls required for complying with this rule consume energy. Thus, this rule will be a net energy consumer not an energy saver.

Additionally, the proposal rightfully does not require implementing audit results and does not include costs and burdens for doing so. Thus, there is no basis for assuming the audit requirement saves any energy.

Comment: A review of the proposed rulemaking record suggests that EPA's identification of the combustion units that comprise the population of "Major Source Boilers and Process Heaters" within the United States is inconsistent. For example, page 3 of the April 2010 ERG Memorandum ["MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Prodess Heaters NESHAP-Major Source"] states "there are 13,555 boilers/process heaters currently in operation at major sources in the United States." However, Table 1 of Part B of the Supporting Statement for Information Collection Request No. 228 6.01 (ICR) indicates that there are 13,052 such combustion units, and Page 4 of the March 2010 ERG Memorandum ["Methodology for Estimating Impacts from Boilers and Process Heaters at Major Sources of HAPs"] indicates that there is "a total of 13,434 unique boilers and process heaters" in the United States.

Comment: If this rule remains in its current form, SKF's plans to invest $300 million in two industrial scale projects converting both its U.S. mill operations to renewable biomass cogen facilities will be lost. The new facilities would include bubbling fluidized bed boiler system and condensing extraction turbine generators designed to produce approximately 31 megawatts of renewable electricity for the region and also supplying the facilities' thermal requirements, replacing natural gas.

The cogeneration facilities would be fueled 100 percent by woody biomass or a combination of wood and recycled pulp mill residue. Significant investments have been made in both states to secure proper engineering and design, environmental permitting, electrical interconnection, and fuel availability studies.

The two projects would take approximately two and a half years to complete and include the hiring of 400 contract employees to help in construction, with an additional 60 employees hired for operation of the facility.

The local logging and trucking industry can expect to see an additional 200 jobs to carry the increased load. We want to continue with this project.

Comment: The estimate of the number of boiler and process heaters impacted by this proposal may be significantly understated. The 1993 proposal for the vacated Boiler and Process Heater NESHAP estimated at 68 FR 1687 (January 13, 2003) that there would be a total of 58,200 affected existing units versus the current estimate of 13,555, suggesting an under-counting by more than a factor of 4. That original estimate was based on input from a vast number of sources during the Industrial Combustion Coordinated Rulemaking (ICCR) effort. Similarly, the 1993 proposal estimated 3463 new units per year rather than the 46 units per year estimated here. The RIA for that rulemaking [Footnote: EPA-452/R-04-002 (February 2004)] details the development of their estimate in Section 3. EPA should explain how they have reconciled the large difference in the estimates of existing units between the two phases of this rulemaking and re-visit its boiler inventory as appropriate.
* The RIA [Footnote: EPA-HQ-OAR-2002-0058-0810] reports there are 199 existing units nationally that fire Gas 2 (gases other than natural gas and refinery gas). This is clearly an unreasonably low number. The American Petroleum Institute has indicated that their members alone account for more than 180 boilers and process heaters in Gas 2 service at major sources [Footnote: EPA-QH-OAR-2002-0058-0851]. Since the RIA estimates, in Table 3-1, annualized O&M costs of $500 million per year for just these 199 units, there is a large impact from underestimating their number.
* AF&PA knows of several forest products companies that did not receive an ICR in 2008 and their boilers are not included in the Boiler MACT database. We expect that there are other industries where facilities did not receive an ICR and are not counted in EPA's inventory of major source boilers.

Comment: Overly burdensome regulation will increase greenhouse gas emissions. The definitive study assessing the use of biomass to generate electricity is the May 2008 report entitled Bioenergy and Greenhouse Gases, prepared by Gregory Morris, PhD of The Renewable Energy Program of the Pacific Institute in Berkeley, California. This report notes that the use of biomass avoids the need to combust fossil fuels and also notes that because the combustion of biomass adds no net new carbon to the atmospheric-biospheric circulation system, it is considered “carbon neutral.” Additionally, the study went beyond these comparatively simplistic conclusions to evaluate whether and how the change in terrestrial biomass (i.e., forest thinning) affects overall sequestration as well as the impacts of the change in timing and mix of carbon forms that occur depending on the fate of biomass. This detailed analysis concludes that greenhouse gas sequestration is enhanced by the forest thinning that generates much slash. Of greater importance, however, is the benefit achieved by avoiding open burning and/or decomposition (composting) of slash. Open burning and low-efficiency combustion (i.e., fireplaces) result in much higher emissions of methane, a potent greenhouse gas, as compared to controlled combustion in a boiler. Biomass that is left to decompose in the forest or is land filled degrades into a 50-50 mixture of methane (CH_4) and carbon dioxide (CO_2). The report notes that due to the much higher global warming potential of methane, as compared to carbon dioxide, the global warming impacts associated with decomposition exceed those of controlled combustion even though less carbon is released into the atmosphere from natural decomposition over a 100-year period. In summary, Dr. Morris' team concluded that for every ton of biomass combusted to make electricity, you avoid 0.8 tons of greenhouse gas (CO_2- equivalent) as a result of avoided fossil fuel use. For the biomass originating as slash, there is an additional net reduction of greenhouse gases of between 0.22 tons and 2.28 tons, depending on how the slash would have been handled if it had not been routed to controlled combustion. [Reference: Morris; Bioenergy and Greenhouse Gases, Table 4, Green Power Institute of The Renewable Energy Program of the Pacific Institute, May 2008]. This means that by combusting biomass our facilities reduce GHGs by 1.42 tons for every bone dry ton of slash that they combust.

Therefore, we strongly urge EPA to consider the comments below on how to revise the Boiler and Process Heater NESHAP so as to minimize the potential for boiler closures. It is not economical to haul biomass long distances. The closure of any biomass boiler will have the immediate impact of increasing the amount of biomass that is disposed of through open burning and/or land filling. This will have the exact opposite effect that EPA is hoping for through promulgation of the NESHAP.

Comment: It is not uncommon to have combustion devices below 10 MMBtu/hr heat input at forest product manufacturing facilities. These can be natural gas or propane fired heaters that transfer heat to process equipment through a sealed oil system or they can be water heaters that are larger than 120 gallons and so do not fit within the exemption in the proposed rules. The courts have long established the concept that EPA does not need to concern itself with trivial matters. See, e.g., Alabama Power. This concept is the basis for such things as the exemption of insignificant emissions increases under the major new source review program. The D.C. Circuit has repeatedly upheld EPA's discretion to carve out insignificant emissions source from regulation. Notwithstanding this latent authority, EPA has proposed to regulate all sorts of de minimis boilers and process heaters. We strongly urge EPA to exempt all units with a heat input of less than 10 MMBtu/hr regardless of fuel or unit type. This approach is consistent with the approach taken for the last 30+ years under the NSPS program.

Comment: EPA has proposed to mandate energy efficiency audits as a beyond the floor requirement. We do not believe that EPA has justified the basis for requiring beyond the floor requirements and strongly urge EPA to drop this requirement. While we are in favor of energy efficiency, this imposes an undue burden, particularly in relation to those of our facilities that are in distant locations and for which obtaining the necessary persons to conduct such an audit is difficult and expensive.

Comment: Avoid emission limits for new and existing sources that prevent the use of clean, renewable biomass. As proposed, this rule sets overly stringent emission limits for mercury, dioxin and hydrochloric acid which are present in very small amounts in wood. The costs to achieve these limits will significantly penalize new and existing biomass burning facilities and should be dropped or replaced by alternative work practices standards (for dioxin and mercury). The

proposed limits could require facilities to adopt costly new control equipment which would encourage the use of other non-renewable fuel sources. Emission limits for CO should not be overly stringent so as to discourage the conversion of coal-fired facilities to woody biomass feedstocks or the construction of new wood-based bioenergy facilities.

Comment: Biomass is a "clean" fuel in many of the same respects as the Gas 1 fuels. Perhaps more importantly, biomass-fired boilers produce no net GHG emissions, making the combustion of biomass an important tool in managing and reducing the nation's carbon footprint. Similarly, biomass is an abundant, renewable domestically-produced fuel that can help reduce reliance on foreign sources of fossil fuel and, thus, improve the nation's energy security. Prescribing stringent HAP emissions limitations on biomass boilers will create a significant barrier to the continued use and expansion of biomass fuels.

Comment Excerpt Number: 1

Comment: EPA has undertaken a far-reaching regulatory program that is apparently designed to reduce the use of coal throughout the American economy. The coordinated nature of this program is most evident in the electric power sector, which EPA has undertaken to transform. Upon taking office, the EPA Administrator formulated seven priorities, one of which was to "develop a comprehensive strategy for a cleaner and more efficient power sector, with strong but achievable reduction goals for SO2, NO2, mercury and other air toxics." [Footnote: Federal Implementation Plans to Reduce Interstate Transport of Fine Particulate Matter and Ozone, 75 Fed. Reg. 45,210, 45,227/3 (August 2, 2010), quoting the EPA Administrator's January 12, 2010 outline of the Agency's seven priorities.]This goal was reiterated by EPA in its recently proposed Transport Rule, where the Agency said that "[i]n furtherance of this priority goal, and to respond to statutory and judicial mandates, EPA is undertaking a series of regulatory actions over the course of the next 2 years that will affect the power sector in particular." [Footnote: Federal Implementation Plans to Reduce Interstate Transport of Fine Particulate Matter and Ozone, 75 Fed. Reg. 45,210, 45,227/3 (August 2, 2010), quoting the EPA Administrator's January 12, 2010 outline of the Agency's seven priorities.]

These EPA rulemakings include:

The recently completed National Ambient Air Quality Standards (?NAAQS?) for sulfur dioxide (‘sO2?) and nitrogen dioxide (?NO2?);

The currently proposed new ozone NAAQS and the soon-to-beproposed new PM2.5 NAAQS;

The proposed Transport Rule and expected additional transport rules for the 1997 ozone NAAQS;

The soon-to-be-proposed MACT standards for electric generating units (?EGUs?);

EPA‘s greenhouse gas (?GHG?) regulation under the Prevention of Significant Deterioration (?PSD?) program;

The soon-to-be-proposed New Source Performance Standards for EGUs (including GHG NSPS);

Best Available Retrofit Technology (“BART”) standards for EGUs;

The proposed regulations for coal combustion residues; and

The soon-to-be-proposed water quality regulations for cooling intake structures and soon-to-be-proposed effluent guidelines for discharges from power plants.

Recognizing that all of these regulations are implementing a single overall priority goal and constitute a “comprehensive set of requirements,” [Footnote: Federal Implementation Plans to Reduce Interstate Transport of Fine Particulate Matter and Ozone, 75 Fed. Reg. 45,210, 45,227/3 (August 2, 2010), quoting the EPA Administrator‘s January 12, 2010 outline of the Agency‘s seven priorities.] EPA pledged to coordinate at least its power sector air quality regulations and, to the extent it could under relevant statutory law, to coordinate these power sector air quality regulations with the coal combustion residue regulations and the two power sector water quality regulations. [Footnote: Federal Implementation Plans to Reduce Interstate Transport of Fine Particulate Matter and Ozone, 75 Fed. Reg. 45,210, 45,227/3 (August 2, 2010), quoting the EPA Administrator‘s January 12, 2010 outline of the Agency‘s seven priorities.] EPA further pledged to “engage with other federal, state and local authorities, as well as with stakeholders and the public at large, with the goal of fostering investments in compliance that represent the most efficient and forward-looking expenditure of investor, shareholder, and public funds, resulting, in turn, in the creation of a clean, efficient, and completely modern power sector.” [Footnote: Federal Implementation Plans to Reduce Interstate Transport of Fine Particulate Matter and Ozone, 75 Fed. Reg. 45,210, 45,227/3 (August 2, 2010), quoting the EPA Administrator‘s January 12, 2010 outline of the Agency‘s seven priorities.]

Comment: News accounts recently reported that EPA is well aware that its regulatory efforts in the power sector will increase the costs to coal-fueled EGUs and make them less competitive with renewable resources. In an article entitled “Administration Eyes EPA Rules To Spur Shift From Coal To Renewables,” it was reported that:

Rob Brenner of EPA‘s Office of Air & Radiation told a July 28 meeting of the agency‘s environmental justice advisers that pending rules to control emissions, waste and water discharges from utilities will not only protect public health but add costs to the industry that might make renewable energy a more viable alternative.

“We need to set health-based standards for power plants, and once we do that then they can compete with some of these renewable sources,” Brenner said at the National Environmental Justice Advisory Committee (NEJAC) meeting in Washington, DC. He added later, ?It‘s not really a fair competition because [coal-fueled power plants] are cheaper than they should be because they’re not controlling their pollutants? to their full extent because EPA is yet to issue key rules for the sector, including a mercury air rule and a plan to regulate coal combustion residue. [Footnote: Administration Eyes EPA Rules to Spur Shift from Coal to Renewables, InsideEPA.com (July 29, 2010), at http://insideepa.com/201007291915893/EPA-Daily-News/Daily-News/administration-eyesepa-rules-to-spur-shift-from-coal-to-renewables/menu-id-95.html.]

The same article reported that the White House also understands that transforming the power sector will inevitably result in reduced use of coal and increased use of renewables. Referring to remarks of Nancy Sutley, Chair of the White House Council on Environmental Quality, the article reported that:

Sutley responded that she doubts the existence of so-called clean coal. “Other people have labeled it ?clean coal,” she said. “I don’t know if I would necessarily
concede that that is real. . . . I think in the long run, not just for the [United States] but for the world, that developing and making sure that there is access to these inherently cleaner sources of energy is important. . . . . We need to use energy more efficiently and more cleanly.” [Footnote: Administration Eyes EPA Rules to Spur Shift from Coal to Renewables, InsideEPA.com (July 29, 2010), at http://insideepa.com/201007291915893/EPA-Daily-News/Daily-News/administration-eyesepa-rules-to-spur-shift-from-coal-to-renewables/menu-id-95.html.]

Document Control Number: EPA-HQ-OAR-2002-0058-2787.1
Comment Excerpt Number: 4

Comment: Other EPA regulatory proposals are also part of an overall strategy to reduce the use of coal throughout the economy. This strategy includes the Boiler MACT and Area Source rule at issue here. In the regulatory preamble to the Boiler MACT rule proposal, EPA stated forthrightly that its reason for proposing strict MACT standards for coal boilers and process heaters but only work practice standards for natural gas boilers was to incentivize operators of coal-fueled boilers to switch to natural gas and to discourage operators of natural gas-fueled boilers from switching to coal. [Footnote: National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. 32,006, 32,025/3 (June 4, 2010).] In discussing this issue, EPA made plain that it considers coal to be a "dirty" fuel whose use is inconsistent with the CAA and therefore should be discouraged. [Footnote: National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. 32,006, 32,025/3 (June 4, 2010).] In contrast, EPA considers natural gas to be a "clean fuel" whose use should be encouraged at coal's expense. According to EPA:

In addition, emission limits on gas-fueled boilers and process heaters may have the negative effect of providing an incentive for a facility to switch from gas (considered a "clean" fuel) to a "dirtier" but cheaper fuel (i.e., coal). [Footnote: National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. 32,006, 32,025/3 (June 4, 2010).]

The coal industry also faces a panoply of prospective regulation of the process of producing coal. These regulations include potentially stricter NAAQS for PM10 which may make western surface mining untenable, new restrictions in Appalachia that could result in major reductions in coal mining in that region, and potential imposition of NSPS standards on mining emissions of PM10, methane, volatile organic compounds, and nitrogen oxides. All of these regulations together—EPA's power sector regulations, its regulations for the use of coal in the manufacturing and commercial sectors, and its regulations of coal mining—all have the potential to combine to cumulatively and dramatically reduce coal usage.

Response: See section 7.2 of the Regulatory Impacts Analysis (RIA) for discussion of cumulative impacts.

Commenter Name: Ben Brandes
Commenter Affiliation: National Mining Association
Document Control Number: EPA-HQ-OAR-2002-0058-2787.1
Comment Excerpt Number: 5

Comment: The effect of each EPA individual rule affecting coal, including the rules at issue here, cannot be understood without a cumulative analysis

Given EPA's intent to transform the power sector from what it is today into something different and given its efforts to reduce coal use throughout the economy, EPA must produce a cumulative and economy-wide assessment of this program. As EPA has proposed and finalized each individual regulation, EPA's impact analysis has been limited to the effect of the specific regulation in question. However, to understand the effect that all the rules together will create, it is necessary to study the effect of that program in total.

These effects could be extremely large. For instance, EPA projects the annual cost of the SO2 NAAQS to be $2.9 billion to $3.0 billion in 2020, with most of those costs associated with the power sector; [Footnote: U.S. Environmental Protection Agency, Final Regulatory Impact Analysis (RIA) for the SO2 National Ambient Air Quality Standards (NAAQS) at 7-4, Table 7.1, June 2010 (Docket ID EPA-HQ-OAR-2009- 0769-0059).] the annual cost of the Transport Rule (all in the EGU sector) to be $3.7 billion in 2012 and $2.8 billion in 2014, [Footnote: 75 Fed. Reg. at 45348/1.]with another $2 billion in 2020 and 2025; [Footnote: 75 Fed. Reg. at 45333, Table V.E-1.] the annual cost of the ozone standard to be $32 – 44 billion, again with much of that cost in the EGU sector; [Footnote: U.S. Environmental Protection Agency, Final Ozone National Ambient Air Quality Standards (NAAQS) Regulatory Impact Analysis at 5-23, March 2008 (Docket ID EPA-HQ-OAR-2005-0161-2849) (estimate for 0.065 ppm standard; EPA's proposal is 0.060-0.070).] and the total costs of the coal combustion residue rule to be over $8 billion under the Subtitle D option and over $20 billion with the Subtitle C option. [Footnote: Hazardous and Solid Waste Management System; Identification and Listing of Special Wastes; Disposal of Coal Combustion Residuals From Electric Utilities, 75 Fed. Reg. 35218, 35134, Table 1 (June 21, 2010).] Despite the request from NMA and others for EPA to assess the cost of its GHG regulatory program, EPA has refused to do so, and so that cost is unknown but could be very substantial as well. The other programs identified above will also add significant cost, with the new EGU MACT standards expected to have a very large impact.

But these estimates, as large as they are, mask the overall effect of the regulations when considered cumulatively. The proposed Transport Rule is an example. EPA's draft Regulatory Impact Analysis (?RIA?) for this proposed rule envisions relatively small impacts to coal usage. EPA projects that EGUs can meet the requirements of the rule by switching from high sulfur to low sulfur coal and by installing pollution control equipment, with the result that EPA estimates the retirement of only 1.2 GW of 'small and infrequently used? coal-fueled generating units by 2014. [Footnote: U.S. Environmental Protection Agency, Regulatory Impact Analysis for the Proposed Federal Transport Rule at 14, June 2010 (Docket ID EPA-HQ-OAR-2009-0491-0078).] Based on the foregoing, EPA projects additional cost to the utility industry of $3.7 billion in 2012 and $2.8 billion in 2014 ($2006). [Footnote: U.S. Environmental Protection Agency, Regulatory Impact Analysis for the Proposed Federal Transport Rule at 31, June 2010 (Docket ID EPA-HQ-OAR-2009-0491-0078).]

NMA will comment on these projections in its comments on the proposed Transport Rule, but for purposes here EPA's projection of almost no impact to the coal industry is not meaningful because it is based on an analysis of the Transport Rule in isolation. Thus, even if EPA's projected assessment of the effect of the Transport Rule on coal is correct, that assessment assumes that there are no other forthcoming EPA regulations that will affect the use of coal, an assumption that is clearly wrong. The control options that the Transport Rule RIA envisions appear to exhaust (and likely go beyond exhausting) the ability of the power sector to absorb EPA regulation without large-scale closings of coal plants. The next regulation following the Transport Rule that adds cost to coal-fueled electric generation therefore will force plant closings, but it is incorrect to say that it was that next regulation and not the Transport Rule that causes the plant closings. Both rules and indeed the entire program cause that effect.

EPA‘s push for replacement of coal with natural gas in the national electricity generation mix, as discussed above, will have severe economic impacts. The American Public Power Association recently published a study evaluating the economic impact of relying more heavily on natural gas to generate electricity. [Footnote: Nicholas Braden, New Study Examines Economic Impacts on Utilities if Carbon Emission Rules Cause Shift from Coal to Natural Gas (Amer. Pub. Power Assn., Wash., D.C.), July 7, 2010 (news release).] It provides insights into the potential cumulative economic impacts of the numerous recent rulemakings, proposed rules and forthcoming proposals that focus on coal-based electricity generation. According to the study, the total cost of replacing all existing coal generation with gas would be $743 billion. The study estimates that the cost of just replacing the existing 335,000 MW of coal-based generation would cost $335 billion. The need for new pipeline and storage capacity would be another major hurdle to this fuel switching and the study estimates this would cost $348 billion. The remainder of the total costs would entail necessary changes in the way natural gas is managed in the U.S. energy system, investment in training new staff to deal with the fuel changes, among other changes in power support structure.

EPA itself recognizes the need for cumulative analysis in an analogous situation. EPA requires that EPA reviewers of Environmental Impact Statements (“EISs”) under the National Environmental Protection Act (“NEPA”) take cumulative impacts into account, including consideration of ?impacts that are due to past, present, and reasonably foreseeable actions.” [Footnote: U.S. Environmental Protection Agency, Consideration of Cumulative Impacts in EPA Review of NEPA Documents (May 1999) at 10.] According to EPA, in assessing environmental impacts, it is necessary to assess “[t]he combined, incremental effects of human activity” rather than just the impacts of the particular action for which federal approval is sought. [Footnote: U.S. Environmental Protection Agency, Consideration of Cumulative Impacts in EPA Review of NEPA Documents (May 1999) at 1.] This is based on the recognition that individual actions “may be insignificant by themselves,” but that cumulative impacts accumulate over time, from one or more sources and these cumulative effects must be taken into consideration. [Footnote: U.S. Environmental Protection Agency, Consideration of Cumulative Impacts in EPA Review of NEPA Documents (May 1999) at 10.]

The Council on Environmental Quality (“CEQ”) also requires cumulative impact analysis in EISs. CEQ regulations require that agencies considering major actions that could affect environmental quality consider the “overall, cumulative impact of the action proposed (and of further actions contemplated).” [Footnote: 35 Fed. Reg. 7390, 7391 (1970). It should be emphasized that CEQ does not distinguish between cumulative analysis of environmental impacts and of socioeconomic impacts. Under CEQ regulations, agencies must examine the effect of the proposed action on the “human environment.” 40 C.F.R. § 1508.14 states that “human environment” shall be interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment.” While “economic or social effects are not intended by themselves to require preparation of an environmental impact statement," "[w]hen an environmental impact statement is prepared and economic or social and natural or physical environmental effects are interrelated, then the environmental impact statement will discuss all of these effects on the human environment." This applies to cumulative analysis: where socioeconomic effects accumulate from multiple actions, they must be assessed cumulatively, just as environmental effects must be assessed cumulatively. Thus, cumulative analysis is as relevant for examining socioeconomics as it is for analyzing environmental impacts.]

EPA's and CEQ's reasons for requiring cumulative impact analysis in EISs apply with equal force to economic analysis that EPA performs of its regulations. Where effects of a proposed action accumulate with those of other related actions, examining the effects of the proposed action in isolation will mask the overall effect of the action. That is as true for EPA's regulatory efforts to reduce coal usage as it is for environmental analysis in the NEPA context. To again cite the proposed Transport Rule as an example, as stated, EPA concludes that the rule will not materially affect the use of coal for electric generation. [Footnote: 75 Fed. Reg. at 45357/1.] But under the rationale of CEQ's NEPA regulations, cumulative impact analysis should be conducted because "[c]umulative impacts can result from individually minor but collectively significant actions taking place over a period of time." [Footnote: 40 C.F.R. 1508.7.]

The same is true for EPA's analysis of the proposed Boiler MACT rule specifically at issue here. EPA's RIA concludes that the rule will have only relatively minor effects on production costs for the sectors of the economy affected. But EPA's analysis is rudimentary and only takes into consideration increased engineering costs and does not examine (at least so far as NMA can tell) fuel-switching. Yet, as stated above, the rule is designed to encourage coal boilers to fuel-switch to gas and to discourage gas-fueled boilers from fuel-switching to coal. Moreover, the proposed rule is just one of a series of rules apparently designed to reduce coal use in the United States. Even if the boiler MACT in and of itself did not significantly affect coal usage (a conclusion that cannot be drawn from the face of the RIA), that result may be masking a much larger effect on coal usage when seen in context of EPA's overall program. Discerning whether that overall effect exists is the central purpose of cumulative impact analysis and the reason why such analysis is required in EISs.

Response: See section 7.2 of the Regulatory Impacts Analysis (RIA) for discussion of cumulative impacts.

Comment Excerpt Number: 6

Comment: Executive Order 12866 specifically requires cumulative analysis as follows:

Each agency shall tailor its regulations to impose the least burden on society, including individuals, businesses of differing sizes, and other entities (including small communities and governmental entities), consistent with obtaining regulatory objectives, taking into account, among other things, and to the extent practicable, the costs of cumulative regulations. [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735 (Sep. 30, 1993).]

This requirement for cumulative analysis stems from the regulatory philosophy of Executive Order 12866 that the need for and effects of government regulatory actions should not be examined in isolation but instead on an overall and coordinated basis. The preamble to the Order found that the then current regulatory system did not work in a way that produced efficient results or regulations that were "effective, consistent, sensible, and understandable." [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735 (Sep. 30, 1993).] The first objective of the Order, therefore, was to "enhance planning and coordination with respect to both new and existing regulations." [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735 (Sep. 30, 1993).] In that vein, the main administrative provisions of the Order—an interagency Planning Mechanism, the requirement that each agency produce a Unified Regulatory Agenda and develop a Regulatory Plan, the requirement for a Regulatory Working Group and the provision for quarterly Conferences among OIRA and state, local and tribal governments— were all included to enhance coordination of any specific regulation proposed by an agency with that agency's other existing and contemplated regulations, with other regulations of other agencies, and with the President's overall regulatory priorities. [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735 (Sep. 30, 1993).]

The Statement of Regulatory Philosophy and Principles in Executive Order 12866 also stressed the need for coordination. This Statement provides that "[i]n deciding whether and how to regulate, agencies should assess all costs and benefits of available regulatory alternatives." [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735 (Sep. 30, 1993).] Agencies are instructed to "examine whether existing regulations (or other law) have created, or contributed to, the problem that a new regulation is intended to correct and whether those regulations (or other law) should be modified to achieve the intended goal of regulation more effectively, [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735-36 (Sep. 30, 1993).] to "base its decisions on its best reasonably obtainable scientific, technical, economic, and other information concerning the need for, and consequences of, the intended regulation;" [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51736 (Sep. 30, 1993).] and to "avoid regulations that are inconsistent, incompatible, or duplicative with its other regulations or those of other Federal agencies. [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51736 (Sep. 30, 1993).] Indeed, the preamble to the Executive Order states that ?[t]he objectives of this Executive order are to enhance planning and coordination with respect to both new and existing regulation...." [Footnote: Exec. Order No. 12,866, 58 Fed. Reg. 51735 (Sep. 30, 1993).]

This requirement for coordinated government action based on coordinated and cumulative analysis built on the same requirement in Executive Order 12291, the predecessor order to Executive Order 12866 and the Order which first required agencies to prepare Regulatory Impact Analyses. Executive Order 12291 required agencies, in promulgating new regulations, to "tak[e] into account the condition of the particular industries affected by regulations . . . and other regulatory actions contemplated for the future.” [Footnote: Exec. Order No. 12,291 at 2(e) (emphasis added).]

The Executive Order 12866 requirements for coordinated and cumulative analysis apply with particular force to EPA‘s efforts to remake the power sector and its apparent effort to reduce coal usage throughout the economy. As shown above, each individual regulation that EPA promulgates in this area, including the Boiler MACT rule and Area Source rule at issue here, is part of a single overall program with cumulative consequences.

Moreover, EPA cannot say that cumulative analysis is not “practicable” within the meaning of section 1(b)(11) of Executive Order 12866. EPA obviously has very sophisticated modeling techniques at its disposal. If in any one rulemaking EPA believes that it cannot anticipate and therefore assess the effects of future rulemakings, EPA can assess a range of possible future regulation. Certainly, the fact that EPA has indicated that it has an overall program in furtherance of one of the Agency‘s seven priorities suggests that EPA has a fairly concrete idea of the range of regulatory outcomes that it anticipates. Alternatively, EPA can delay any particular rulemaking until it has better information about future regulatory requirements that it intends to impose. What EPA cannot do, however, is to follow its current regulatory course, where the Agency analyzes individual rulemaking effects in isolation, as if there is no overall regulatory context.

Response: See section 7.2 of the Regulatory Impacts Analysis (RIA) for discussion of cumulative impacts.

Comment: The Specific Cumulative Impact Assessment Requested

NMA believes that the cumulative impact assessment should examine the following factors:

Overall impacts on the economy. Specifically, the effect on GDP and jobs. In this regard, some of EPA‘s regulations (in particular, the NAAQS) will not just affect energy but will affect other sectors of the economy as well both directly (for example, through direct regulation of manufacturing sources) and indirectly (for example, through increased energy costs). EPA should examine all reasonably foreseeable effects of its regulations on the overall economy.

Energy. This part of the analysis should include impacts on energy production and usage, energy shortages, energy costs, including fuel costs and retail electricity prices, and energy employment should be determined. Changes in the energy mix in the United States should be shown over time, including electric capacity additions and reductions by fuel type. Employment and energy cost impacts should be estimated for each energy sector.

Competitiveness. This part of the analysis should include impacts on industrial and manufacturing production and competitiveness. EPA should determine the impacts of regulation on cost of production and employment in the relevant sectors, and the extent to which production and jobs will be reduced as a result of higher costs and foreign competition.

Study design. Scenarios should be constructed for a business-as-usual case (without adoption of the contemplated regulations) and a case where EPA adopts the contemplated regulations. Additional scenarios may be included to test the findings under different appropriate assumptions. Where EPA regulation does not directly regulate but instead requires states to adopt regulations meeting EPA standards (for instance, EPA regulation under the NAAQS program and NSR/PSD program), EPA should estimate state regulatory responses, using a range if necessary. All assumptions, analytical methods and underlying data (or appropriate citations to data sources) should be provided. All impacts should be broken down on a state-by-state basis. Regulations included in the study should not be limited to just those listed in NMA's comments but should include any other EPA regulations that EPA believes will affect the nation's economy, production and usage of energy and manufacturing.

Response: See section 7.2 of the Regulatory Impacts Analysis (RIA) for discussion of cumulative impacts.

Comment Excerpt Number: 3

Comment: II. EPA Should Set Emissions Standards that Maximize Net Social Benefits

Given the mandate from Executive Order 12,866, EPA's default practice should be to design regulations that maximize net social welfare, unless directly forbidden by statute. Since Section 112(d)(2) cannot be read to prohibit such a goal, the agency should pursue any beyond-the-floor regulations where benefits justify the costs. This interpretation is not forbidden by the D.C. Circuit opinion in Sierra Club v. EPA (2004), and EPA's regulatory impact analysis indicates that, particularly for the Major Source Proposal, more stringent emission standards than those currently proposed would increase social welfare.

Response: See section 7.2 of the Regulatory Impacts Analysis (RIA) for discussion of cumulative impacts.

Comment Excerpt Number: 5

Comment: Administration Policy Requires EPA to Pursue Welfare-Maximizing Regulations

Given the rationales for public regulation of private entities and the directives of Executive Order 12,866, EPA should interpret Section 112(d) to allow the agency to set all emissions standards that maximize net social welfare.

Typically, entities will not voluntarily reduce their own HAP emissions because they do not pay the full costs of those emissions. Air pollution is a classic "negative externality": the harmful effects of pollution are mostly felt by members of the public who cannot directly influence the production of that pollution. Basic micro-economics holds that when an entity does not pay for an effect it
produces, its optimal behavior will not take that effect into consideration. In the status quo, major and area sources of HAP do not pay for the full effect of their emissions. [Footnote: Some entities that will be regulated under the rule may currently pay for emissions which are correlated with the emission of HAP (e.g., sulfur dioxide). While this may encourage some reductions in HAP, it will not necessarily lead to the optimal amount of reductions.] Because there are positive costs (both health effects and environmental effects) from the emission of HAP and regulated entities are not paying for these costs, these entities are currently "over-producing" HAP emissions.

The existence of a negative externality does not necessarily dictate that all HAP emissions must be eliminated. Rather, society should be willing to pay for any change which produces higher benefits than costs. The costs of regulating HAP emissions will be passed from individual sources to society as a whole in a variety of ways: consumers may face higher prices as the cost of production rises; business owners and investors may lose income as regulated entities lose profits; government entities that operate regulated boilers may have to increase taxes or decrease their expenditures in other areas. A wide variety of benefits will counteract these costs, including decreased mortality from lower particulate matter emissions. If the benefits of the proposed rule are higher than the costs, society as a whole is better off.

The goal of maximizing net benefits is enshrined in administration-wide policy under Executive Order 12,866. The Order directs federal agencies to "assess all costs and benefits of available regulatory alternatives" in deciding how to regulate, and then "select those approaches that maximize net benefits unless a statute requires another regulatory approach." [Footnote: Exec. Order No. 12,866 §1, 58 Fed. Reg. 51,735 (1993).] Since, as demonstrate above, EPA has statutory authority to consider net benefits under Section 112(d), the directives of Executive Order 12,866 apply.

Response: See section 7.2 of the Regulatory Impacts Analysis (RIA) for discussion of cumulative impacts.

Executive Order 13175, Consultation and Coordination with Indian Tribal Governments

Commenter Name: Ben Brandes
Commenter Affiliation: National Mining Association
Document Control Number: EPA-HQ-OAR-2002-0058-2787.1
Comment Excerpt Number: 2

Comment: EPA‘s regulatory agenda for the power sector will almost certainly significantly reduce the use of coal for electric generation. While EPA so far has not done any study of the cumulative impact of these regulations on coal use (or otherwise), the contractor EPA uses to model impacts of individual regulations recently produced its own analysis showing that just the EGU MACT standards alone will force major retirements of coal-fueled power plants. [Footnote: Federal Implementation Plans to Reduce Interstate Transport of Fine Particulate Matter and Ozone, 75 Fed. Reg. 45,210, 45,227/3 (August 2, 2010), quoting the EPA Administrator‘s January 12, 2010 outline of the Agency‘s seven priorities.] Forced retirements will have substantial negative economic impacts nationally, but will also have severe impacts locally, as exemplified by the Arizona Hopi and the Navajo Generation Station:

“Scott Canty, the Hopi Nation‘s general counsel, explained to a panel of lawmakers on Nov. 2 that closure of the Navajo Generating Station would cripple the tribal government. The Hopi Nation relies heavily on coal revenues to fund its government, Canty said. About 88 percent of the tribal government‘s budget comes from revenue generated by coal-fired energy production at the Navajo Generating Station, Canty said. . . . The EPA has proposed rules that would require the power plant to install expensive emissions equipment to address visibility impairment issues at the Grand Canyon. But the plant‘s owners and the tribes argue that the retrofit is too costly.” [Footnote: Luige del Puerto, Hopi Nation in Arizona appeals for help as coal plant face disclosure, ARIZ. CAP. TIMES, Nov. 3, 2009, available at http://www.allbusiness.com/government/government-bodies-officesregional/13389633-1.html.]

Response: EPA is only aware of a couple of instances as provided by the commenter of ICI boilers on tribal lands. The effect of this final rule on communities of tribal governments would not be unique or disproportionate to the effect on other non-tribal communities. To the extent possible, and as discussed in the preamble we have made several changes to reduce the burden of the final rule.

Comment Excerpt Number: 3

Comment: All APPA members are covered under the Unfunded Mandates Reform Act (UMRA) as they are entities of state or local governments.

Response: See the preamble for a summary of the Unfunded Mandates Reform Act Analysis for the Proposed Industrial Boilers and Process Heaters NESHAP.

Commenter Name: Michael J. Nasi
Commenter Affiliation: Gulf Coast Lignite Coalition
Document Control Number: EPA-HQ-OAR-2002-0058-2800.1
Comment Excerpt Number: 1

Comment: The UMRA cost-benefit analysis fails to factor in the disproportionate economic impact on coal-fired units.

The Unfunded Mandates Reform Act (UMRA) of 1995 requires a cost-benefit analysis. [Footnote: National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. 32006, 32043 (June 4, 2010) (to be codified at 40 C.F.R. pt. 63.] In itsanalysis,the EPA examines future compliance costs and an disproportionate budgetary effects on the proposed rule on any particular areas of the country, State or local governments, types of communities (e.g., urban, rural) or particular industry segments." [Footnote: National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. 32044 (June 4, 2010) (to be codified at 40 C.F.R. pt. 63.]

GCLC respectfully disagrees with the EPA's assessment, The proposed MACT floors could in fact create a disproportionate budgetary effect on different areas of the country, types of communities. and particularly industry segments.

EPA is proposing different MACT floors for boilers based on the type of fuel that is fired. While some fuel sources are being allowed to rely solely upon work practice standards, coal-fired units, for example. will he required to install emission controls and monitoring equipment ranging from activated carbon injection, wet scrubbers, and other emission controls to continuous emissions monitor (CEMs) for opacity, and for larger units, particulate matter (PM). These emission controls and monitoring devices will be costly to obtain, install. and maintain; include costs associated with training, monitoring, and reporting of the emissions; and potentially conflict with other pollution reduction goals (e.g., coal combustion product recycling).

EPA recognizes that it cannot, or should not mandate fuel switching, yet the proposed 'NESI-IAP rules create regulatory burdens based solely on stated policy preference regarding fuel type. GCLC questions how EPA can proceed with the proposed approach without a comprehensive evaluation of whether and to what extent there will be a disproportionate impact on facilities with coal-fired units and those regions that are already dependent upon coal for their energy source.

Response: See the preamble for a summary of the Unfunded Mandates Reform Act Analysis for the Proposed Industrial Boilers and Process Heaters NESHAP.

Regulatory Flexibility Act as Amended by the Small Business Regulatory Enforcement Fairness Act (RFA) of 1996 (SBREFA), 5 U.S.C. 601 et Seq.

Commenter Name: Theresa Pugh
Commenter Affiliation: American Public Power Association (APPA)
Document Control Number: EPA-HQ-OAR-2002-0058-0846.1
Comment Excerpt Number: 2

Comment: More than 90% of public power systems meet the definition and qualify as small businesses under the Small Business Act and the Small Business Regulatory Enforcement and Fairness Act of 1996 (SBREFA).

Response: EPA appreciates the concerns of the regulated small entities. During this rulemaking process we have incorporated several suggestions from the small business panel and we have made several changes in the final rule to reduce the burden on all sources, including small entities. See the Final Regulatory Flexibility Analysis (FRFA) section of the Regulatory Impact Analysis (RIA) which has been prepared for this rule for further discussion of the impact on small entities.

Comment: The PTPC mill has upgraded its operations and is in compliance with MACT I and MACT II, along with other federal and state compliance requirements. It's also considered a small pulp and paper company as defined by the Small Business Administration.

The mill has two boilers that are subject to these rules -- a 1976 Stoker-Fired Biomass Boiler and a 1996 Oil-Fired Package Boiler that's used as a backup or auxiliary boiler.
Here are our concerns: PTPC volunteered to be on the SBA committee to review the impact Boiler MACT would have on small businesses. We are dismayed that the recommendations from that work have been, chiefly, ignored.

Response: See response to comment EPA-HQ-OAR-2002-0058-0846.1, excerpt 2 for discussion of impact on small entities.

Commenter Name: Thomas P. Greene, III
Commenter Affiliation: Atlantic Wood Industries, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-1599.1
Comment Excerpt Number: 5

Comment: Most importantly, the wood utility pole and piling industry is made up of many small and family-owned businesses with modest earnings. The cost of required controls would be millions of dollars per boiler at a typical plant like ours which would be unaffordable.

Response: See response to comment EPA-HQ-OAR-2002-0058-0846.1, excerpt 2 for discussion of impact on small entities.

Commenter Affiliation: American Petroleum Institute and National Petrochemical and Refiners Association
Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 10

Comment: Furthermore, as discussed in item 4 below, the details of the work practice requirements in the proposal go beyond those described to the Small Business review panel and the costs and burdens will be much higher than EPA estimated and thus will have a significant impact on small businesses. It is highly likely many small businesses will become non-viable as a result of this rule.

Response: See response to comment EPA-HQ-OAR-2002-0058-0846.1, excerpt 2 for discussion of impact on small entities.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 12

Comment: The small business analysis appears to have been focused on the work practice requirements on the assumption that small businesses only have units that are subject to those requirements. We believe that assumption is false for many situations, because many small businesses have units over 10 MMBTU/hr and units that fire solid, liquid, or gas 2 fuels and thus are subject to emission limitations under this proposal. Given the tremendous costs and questionable feasibility of complying with the proposed emission limits, it is likely many small businesses with such equipment will be unable to make the investments required for compliance and thus will be significantly impacted. There is no relationship between the number of employees in a company (the basis for the small business classification) and the number or type of boilers and process heaters or the emissions from a site that is major for HAP. EPA should re-evaluate the small business impacts.

Response: See response to comment EPA-HQ-OAR-2002-0058-0846.1, excerpt 2 for discussion of impact on small entities.

Paperwork Reduction Act

Commenter Name: Matthew Todd and David Friedman

Commenter Affiliation: American Petroleum Institute and National Petrochemical and Refiners Association
Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 7

Comment: Overall, we believe the information available to OMB is incomplete and incorrect and the Information Collection Request should be denied and OMB should require new reviews under the PRA and the other regulations applicable to this rulemaking, focusing on the negative impacts of the proposal on jobs and the economy.

Response: EPA has updated its estimates based on a revised inventory, modified testing and monitoring requirements, and considered many commenter suggestions in the revised ICR.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute and National Petrochemical and Refiners Association
Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 11

Comment: The Agency has grossly underestimated the number of controls that will be required and thus underestimated the numbers of continuous monitors and other records and reports that will be required. Thus, they have failed to include all of the recordkeeping and reporting associated with controls that will be required for Gas 2 (and Gas-1fired units under the alternate proposal) and for liquid fired units.

The analysis has failed to include all of the burdens, recordkeeping and reporting associated with the QA/QC of parameter and emissions monitors. An effort appears to have been made to include the initial effort associated with developing a monitoring QA/QC plan, but there does not appear to have been any upkeep estimate for that plan or incorporation of the extensive on-going burdens associated with the requirements specified in proposed §63.7525 for all compliance monitors. This is particularly important for CEMS, because the burdens associated with quarterly audits and annual certifications are very extensive.

The burden analysis does not appear to include annual performance tests for all units subject to emission limits. While there is some provision for fuel testing and performance test skip periods for some pollutants in the proposal, it requires annual performance testing for dioxins/furans (D/F) for all units subject to D/F limits. Since most of the cost and burden of a performance test is associated with performance test setup and measurement of stack gas properties, there is little cost or burden difference between tests for D/F and tests for all of the regulated pollutants.

The burden estimate fails to address the large effort that will be associated with permitting all of these changes and performing the New Source Review analyses required because of the increases in criteria pollutants that will result from this proposal.

The burden estimate incorporates a small amount of time for an initial reading of the regulation, but provides for no ongoing training or for the massive effort associated with incorporating these new requirements into site compliance programs and permits, both initially, and as new boilers and process heaters are added.

Response: The ICR computes the burden for the first three years after the rule is signed. Since existing facilities have three years to comply with the rule, upkeep of the monitoring plan is not included in this ICR. Costs associated with audits and certifications of CEMS are already included in the annual costs line of the burden estimate tables for the different monitoring equipment; RATA costs are calculated using data from U.S. EPA CEMS Cost Model (version 3/07/2007). For each unit with emission limits, annual performance test costs are included in year 3 for those units which performed their initial testing in year 2. EPA agrees that training hours are necessary and has incorporated this into the revised burden estimates.
Changes in burden estimates for the New Source Review program are covered under a separate ICR, "Prevention of Significant Deterioration and Non-Attainment New Source Review (Final Rule for Flexible Air Permits) OMB Control Number 2060-0003. After the final boiler rule is published, the next revision of the Flexible Air Permits ICR will adjust its estimates for NSR burden and costs. Please see the preamble for a response on how EPA estimated the number of units expected to install controls.

Comment Excerpt Number: 13

Comment: The burden estimate incorporates a small amount of time for an initial reading of the regulation, but provides for no ongoing training or for the massive effort associated with incorporating the new requirements into site compliance programs and permits, both initially and as new boilers and process heaters are added. EPA should add this cost to its burden estimates.

Response: See response to comment EPA-HQ-OAR-2002-0058-0851.1 excerpt 11 for how we incorporated training costs and considered permitting burden.

Commenter Name: James P. Brooks
Commenter Affiliation: Maine Department of Environmental Protection, Bureau of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-2746.1
Comment Excerpt Number: 16

Comment: The Maine DEP also respectfully requests that EPA provide additional Section 105 funding to states for implementation of the Area and Major Source Boiler MACTs. These rules will affect an enormous population of boilers nationwide, will result in the need for thousands of permit amendments, and will put a tremendous strain on already stretched state resources.

Response: The EPA appreciates the concerns related to the burden on state agencies. Providing additional funding under Section 105 of the Clean Air Act is an important consideration but outside the scope of this particular rulemaking. The Agency has revised testing frequencies and other compliance and permitting provisions in the rule to reduce the burden on states.

Commenter Name: Randall D. Quintrell
Commenter Affiliation: Georgia Paper and Forest Products Association, GPFPA
Document Control Number: EPA-HQ-OAR-2002-0058-2905
Comment Excerpt Number: 16

Comment: EPA's supporting rationale in the preamble that the extensive testing under the proposed Boiler MACT requirements would improve their database is hardly justification for this unreasonable testing burden, even if it could generate valid data. The Boiler MACT should not be used as a tool for EPA to collect data at the expense of the regulated community. The excessive testing burdens in the Rule appear to us to be just that. If EPA legitimately believes it needs more data, then it must follow the protocols of the Paperwork Reduction Act (PRA), submit a formal Information Collection Request (ICR) and justify the cost.

Response: See Preamble for a discussion of modifications made to reduce testing and monitoring burden on affected entities.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 22

Comment: There will be a substantial increase in the number of compliance tests and CEMS certification tests. The Division currently has 4 positions available for reviewing test protocols, observing the tests and reviewing test reports. The Division's workload is going to increase and current budget constraints simply mean that the agency will not be able to witness all tests.

Response: See the preamble for response to how EPA modified CO limits and compliance mechanisms, which reduce the number of required RATAs.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 23

Comment: New or existing boilers and process heaters are required to conduct initial and annual performance tests. The increase in compliance tests will impact the state financially. The state currently spends approximately 3 business days per compliance test observation, per source. The work load includes reviewing compliance test protocols, observing the test, and reviewing the final test report. EPA estimates there are currently 13,555 boilers and process heaters at major sources.

Response: See the preamble for response to how EPA modified CO limits and compliance mechanisms, which reduce the number of required RATAs.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 25

Comment: The proposed regulation requires the use of CO CEMS. The CO CEMS will be required to be certified through RATAs and audits. State, local, and tribal agencies review and observe the quarterly RATAs. This will increase the work load for agencies and current funding sources do not provide adequate funds to meet the new demands.

Response: See the preamble for response to how EPA modified CO limits and compliance mechanisms, which reduce the number of required RATAs.

Comment: The burden estimate incorporates a small amount of time for an initial reading of the regulation, but provides for no ongoing training or for the massive effort associated with incorporating the new requirements into site compliance programs and permits, both initially and as new boilers and process heaters are added. EPA should add this cost to its burden estimate.

Response: See response to comment EPA-HQ-OAR-2002-0058-0851.1 excerpt 11 for how we incorporated training costs and considered permitting burden.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 134

Comment: EPA has not included the cost of the ongoing energy management program in its burden estimates. This proposed requirement for an energy management program expands a one-time initial energy audit requirement to an ongoing effort that adds continuing personnel, monitoring and recordkeeping requirements. EPA should add this cost to its burden estimates.

Response: The ICR computes the burden for the first three years after the rule is signed. Since existing facilities have three years to comply with the rule requirements the ongoing energy management program is not included in this initial ICR, but will be incorporated in future ICR renewals for this rule.

Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations

Comment: [Question from panelist] you mentioned a cumulative impact analysis. Do you have information available as to how that's being carried out?
MS. BABICH: I think that if you look at the California EPA process that's going on they have a Cumulative Impacts Precautionary Approaches Work Group that we fly up to Sacramento to be a part of. And what they've just finished wrapping up, along with some assistance from the University of Berkeley and Dr. Amy Kyle, is really looking at the data gaps that are out there. And I don't necessarily mean that we need to spend 40 years collecting more data. We obviously need to move forward on the data we have. But they have a very good process and she's a very commendable toxicologist who can actually give us an honest opinion.
That's what we're looking for. We don't need to fudge it one way or the another. But let's really look at where we are and see where these data gaps are so that we can make better informed decisions. So I would say that you might want to plug into that or Dr. Joe Lew (phonetic) from the California Environmental Rights Alliance who couldn't be with us here today. He has been working as a representative of E.J. communities on that panel and I'm sure that he could give you information in a way that would be easier for you to process than I can probably do at this time.

Response: The cumulative risk sources listed by the commenter have been noted. We appreciate the information and agree that closing the data gaps will better inform regulatory decisions. Risk issues will be addressed during the residual risk review phase, including any consideration of cumulative risks of HAP.

Comment: There has been a lot of talk over the past couple of years from EPA about protecting environmental justice communities ensuring that environmental justice is a part of the decision-making process of everything that EPA takes on. I think that this is a clear example where better protecting and better serving environmental justice communities would be better served by a stricter interpretation of what is a solid waste; as well, using carbon monoxide as a surrogate for other sorts of VOCs, especially those which we struggle so mildly with in the Houston area. I don't think that, again, is going to serve environmental justice communities well.

Response: As the commenter notes, this rule and the definition of solid waste are interconnected. EPA recently tightened its definition of solid waste in a rule that clarifies which non-hazardous secondary materials are considered solid waste. The major source rule for boilers establish limits for CO. By imposing emission limits on carbon monoxide, EPA expects to reduce emissions of formaldehyde, acetaldehyde, and polycyclic aromatic hydrocarbons. Further discussion on this issue is found in responses to comments related to the use of CO as a surrogate for organic HAP.

Comment: MR. THOMAS: How are you defining "environmental justice communities"? You have to -- I know it's a very complicated issue.
MR. TEJADA: Yeah, the EPA doesn't even really have a good definition of environmental justice communities, and I think that's one of the things that NEJAC is -- is struggling with, as well, finding exactly what it means to take environmental justice and give it its full measure in the decision-making process, exactly where that comes into the decision-making process, exactly who are environmental justice communities. That's one of the things that I think that is most challenging about Houston, is that it's not just the usual suspects. I think most of the ten-point communities of major industry in the Houston area are obviously environmental justice communities following the regular interpretations of low socioeconomic levels, the racial profile of the community, its proximity to major sources, is a good start.

But especially in Houston, one of the
things that my organization has been struggling with a lot over the past year is that we are finding small, yet major sources of pollution buried within our entire community from unusual suspects, such as automotive mechanics, things such as metal fabrication or foundries.

So I think these sorts of rules that deal
very specifically and are very well defined in things such as a boiler versus an incinerator or solid waste, especially in the Houston region, which I think even by a narrow definition of environmental justice community would probably have more EJ communities than anywhere else in the United States; that is further multiplied when you look at Houston itself being the largest city without any form of zoning in the United States.

If you actually pull back the cover of
Houston, you start to find many communities sprinkled throughout the entire region that face very specific, but very serious threats from air emissions. We're dealing with one about a half mile from downtown right now. A historic black community that has a boundary in the center of the community, and that boundary from its permit, which was only taken out a few years ago, its historic operational practices, the emissions and locations of the different units within the facility that, that community has been very poorly served by a poor regulatory definition of how a boundary of that size should operate.

And this rule or these rules are exactly
the sort that need to be very specific and very well defined in order to better protect exactly those sorts of communities that don't have the profile of Manchester or Galena Park or Baytown.

Response: While the Agency does not have a standard definition of EJ communities, within the context of this rule EPA expects that minority and low income communities will likely experience positive impacts (e.g., reduced incidence of adverse health effects). The demographic data for the Census blocks near these facilities[1] suggest that low-income and minority populations are higher than the national average in these areas in proportional terms. The commenter also points out that EJ communities face serious impacts from air pollution sources, which may vary from community to community, such as the foundry mentioned by the commenter. While the comment on foundries is beyond the scope of the boiler rule, EPA agrees on the importance of well-constructed, specific regulations to limit emissions from specific source categories such as foundries.

Comment: EPA also failed to include
an assessment of individual hot spot EJ communities.
Wilmington is one of those communities that should have
been looked at more thoroughly to identify what the
standard in an appropriate measure to protect a hot spot
EJ community, and we ask that you do that.

Response: EPA's current environmental justice approach is a proximity based analysis that compares aggregate populations in close proximity to the regulated source to national averages. We do acknowledge that examining 'hot spots' may provide additional information about local impacts that could be relevant to local or regional efforts to reduce risk as well as to national rulemakings.

Comment: Your definition of a major source
is not acceptable. Environmental justice communities
want the same air quality standard for all facility
boiler air pollution sources.

Response: We recognize that from the community perspective any source that has the potential to adversely impact the community is a "major" source. However, for the purpose of our rule making, EPA is bound by law to the definition of a major source set forth in the Clean Air Act Amendments Sec. 112 (a) (10 (1). That definition states that a ''major source'' means any stationary source (or group of stationary sources) located within a contiguous area and under common control that emits or has the potential to emit considering controls, in the aggregate, 10 tons per year or more of any hazardous air pollutant or 25 tons per year or more of any combination of hazardous air pollutants.

Comment: Because these devices are so numerous and widespread, their toxic pollution infiltrates communities across the nation. They're harm settles heaviest on those who live near them, communities that are often poorer, less well-educated and minorities. Study after study finds that pollution harms these folks far more than it does others.

Response: The units controlled by this rule are numerous and wide spread. However, "nearness" to one of these sources is not an iron-clad indicator of the extent of exposure or "harm." Emissions models indicate that the concentrations of pollutants are highest in the vicinity of the release point. However, the pollutant concentration (and potential for exposure) steadily decreases as one moves further from the emission's source. But the decrease is not uniform around the source. Lots of things can affect the pollutant path and the rate of dilution. For example predominate wind speed and direction play a major role in determining who experiences the effects. Therefore, it's possible for a community to be adjacent to a source yet experience less exposure than a community further away but in the path of the prevailing wind. Having said that, we believe that the controls placed on these combustion units by this rule will substantially reduce emissions and will provide positive benefits to all those communities previously impacted by the emissions from this source category.

Commenter Name: Los Angeles Public Hearing Transcript

Comment: We have some substantial concerns over aspects of these proposed regulations.
These industrial sources of pollution are ubiquitous throughout the Los Angeles region and, in many cases, are located in low income areas and communities of color. For instance, of the roughly one dozen refineries in our area, most of which are associated with very high health risks, all but one are located in communities of color. Many of these facilities are poorly using boilers that are decades old and contribute to a lot of pollution, both locally and regionally.

Response: As previously indicated, we believe that the controls placed on these combustion units by this rule will substantially reduce emissions and will result in positive benefits to all those communities previously impacted by the emissions from this source category.

Comment: There is study going on in Corpus Christi concerning benzine releases from current existing refineries in the area.
This is conducted by a local group called the Citizens for Environmental Justice, conducted after ten years of refusal to bond the Texas commissioner on environmental quality to conduct such a study. That
year-end study determined there were absorbantly high
benzine levels in people living in the Hillcrest
community immediately adjacent to several refineries in
the northern part of Corpus Christi.
In Addition to that, as we determine now,
as a consequence of that study, that hundreds of
millions of dollars worth of hydrocarbons are in the
ground and the groundwater beneath the Hillcrest
neighborhood currently right now seeping into people's
homes and into their bloodstreams. We would urge that
the EPA -- TCEQ, as well, and specifically the EPA move
toward a more cumulative study of emissions -- to look
at the emissions not just at any one plant, but of all
those in the immediate vicinity, whether it be looking
at SO2 or mercury or lead or particulate matter or what
have you.

Response: EPA agrees that cumulative air emission studies will better inform rulemaking.

Comment: How is EPA evaluating the environmental justice impacts of these rules? In the documents that were provided for the webinar that the Agency conducted last Wednesday -- the rather excellent webinar I might add -– in those documents it described the demographic evaluation of population distribution around the sources impacted by the Boiler MACT CISWI rule and the definition of non-solid hazardous waste.

EPA’s demographic analysis of the industrial boilers rule clearly shows that 33 percent of the population around these existing facilities are people of color, and 29 percent of the population around the CISWI incinerators are people of color. Both analyses demonstrate that areas in closest proximity to these two categories of facilities exceed the percentage of people of color in the nation’s population at large, which is 25 percent.

I want to note that while the demographic analysis represents a significant step forward by EPA in determining the potential impacts of its rulemaking, it is nonetheless an insufficient analysis of adverse impact of the operations of these facilities on the nearby communities.

The demographic analysis also shows that surrounding communities also have higher levels of people living at or below the national poverty levels. EPA’s determination of benefits of these rules to environmental justice communities outweighing impacts is spotty and needs to be expanded to include public health impacts that extend beyond the simple and mere demographic analysis.
[Question from Panelist]In your written comments, the more detailed comments, will you be providing any input to us on how we should factor in the economic impacts to environmental justice, the job losses, plant closures that would take away health insurance and things on how we should account for that?

MS. MILLER-TRAVIS: I wasn’t planning to, but I can now that you’ve asked that question; but let me say this: It is a fairly strong misnomer to believe that or to assume that because a facility is –-

MR. WAYLAND: True.

MS. MILLER-TRAVIS: -- operating in a particular demographic or geographic location that the people who live in closest proximity to that facility necessarily work in that facility or nave any economic benefits. That’s a widely held misunderstanding. And just because a facility is in a location doesn’t mean that the people who live closest to it work in that location and have some economic benefits.

So –- but your question is nevertheless a valid one, and I will try and address it in my written comments.

Response: The development of EJ analysis and its application to rule making is relatively new to EPA. The primary focus to date has been on determining the demographic makeup of those populations in the vicinity of a source and, therefore, potentially affected by a specific rule making. Over time, we expect to improve our methodology for measuring health impacts and the economic impacts mentioned by commenters. The development of a comprehensive Agency-wide technical guidance on how to do an EJ analysis is currently underway. This guidance will contain a major economics component and is anticipated to address economic questions such as those raised here.

Comment: I really wanted to talk a little bit more about the stories of communities that I've been in in terms of there are all kinds of things that are thrown in boilers that are small, medium-sized, large, and essentially exempting facilities across this country from having to install protective controls on those facilities, has continued to put those communities at risk.

Response: The boiler rules adopted by EPA are designed to address the concerns and risks that the commenter mentions. The major source boiler rule will reduce emissions of acid gases, such as hydrogen chloride and hydrogen fluoride, mercury, lead, cadmium, other non-mercury metals, organics, and chlorinated dioxin/furans, while the area source boiler rule will reduce emissions of mercury, non-mercury metals, and organics. This will be the result of emissions limits and work practice standards, which are required for major and area source boilers, respectively.

Comment: The Sierra Club's Environmental Justice and Community Partnership Program, EJCP, has provided support to more than dozens of low income and communities of color in their environmental justice struggles. We work to –- we work with low-income and communities of color to overcome environmental assaults on their lives and communities. The Sierra Club's work is national in scope. We were founded in 1892, and we have about a million members, yet it has a grassroots presence everywhere in the county. It is volunteer based and operated and includes professionals willing to devote their volunteer time to build local communities as well.

We have successfully built such bridges in our EJCP partnerships program in El Paso, Detroit, Flagstaff, Memphis, Minneapolis, New Orleans, Washington, D.C., and the Appalachia region and in Puerto Rico, bringing together Sierra Club volunteers, staff, affected community members to strengthen the fight against environmental injustices.

We want to thank EPA Administrator regarding the Major Source Boilers Rule. We want to thank EPA Administrator Lisa Jackson for taking this step to control the toxic air pollution from chemical plants, refineries, paper mills and other industrial sources that are making our air unsafe to breathe. EPA's new rule will finally make the largest of these facilities control the emissions from their boilers and process heaters. It is really about time. These standards are 10 years overdue. Across the country families and communities need protection these rules will provide.

In addition, once again we appreciate Administrator Jackson's emphasizing environmental justice as one of the main priorities during her tenure. Many environmental justice communities, such as the 48217 Detroit community in which the Sierra Club EJCP program works will greatly benefit from this new rule.

Response: EPA agrees that this rule will have significant benefits to many environmental justice communities.

Comment Excerpt Number: 10

Comment: The EPA should continue to consider the disproportionate impact that incinerators have on poor and minority communities. According to the EPA's webinar on national emission standards for boilers, process heaters and incinerators, [See reference 26 provided by commenter] for populations living near disposal and processing facilities that may receive wastes diverted from incinerators, the results suggest that percentages of low-income and minority populations are slightly higher than national average. These results should not be used to justify avoidance of heightened standards for incinerators because low-income communities are already disproportionately affected by air pollution [See reference 27 provided by commenter]. The pollution from industrial air pollution sources, such as incinerators, accumulates in places where minority populations are disproportionately affected. Id.

The EPA should do more studies to test the background levels of already existing pollution of communities affected by incinerator emissions. Background levels of air pollution in these communities are often higher than in other areas because, in general, low-income neighborhoods experience more of all forms of pollution (including air and water pollution, as well as toxic waste pollution) than do neighborhoods that maintain higher levels of income [See reference 28 provided by commenter].
For example, a biomass incinerator was planned to be built in Springfield, Massachusetts, a city described as already having "an 'F' in air quality" [See reference 29 provided by commenter]. In

fact, Springfield ranks number fourteen on the Asthma and Allergy Foundation of America's ranking of U.S. Metropolitan areas according to prevalence of asthma [See reference 30 provided by commenter]. The EPA should use the results of studies of background emissions to strengthen regulation of emissions; for example, if an inner-city community already has high dioxin emissions, emission standards should be higher [See reference 27 provided by commenter].

Response: We agree with the commenter that the consideration of disproportionate impacts on poor and minority communities is an important priority in rulemaking. We also agree that better background data will improve the rulemaking process for all populations, including minority and low-income populations. In the environmental justice analysis completed for this rulemaking, proximity to a source was used as a surrogate for exposure to air pollutants. EPA also recognizes that the solid waste definition rule is intricately tied to the Boiler rule and that while there may be benefits associated with decreased air emissions from Boilers, there may also be disbenefits associated with diversion of waste for boiler units.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 34

Comment: In its discussion of environmental justice issues, EPA asserts that the rule meets environmental justice concerns because it does not increase HAP emissions in minority and low income areas. We suggest that this is too low a test for disparate impact. If this rule reduced HAP emissions broadly across the country, except in minority and low-income areas, a disparate impact might result. Here, it has been established that industrial boilers are often located in minority/low-income communities and that the reductions in HAPs from the proposed rule will in fact disproportionally impact those communities – but in a beneficial way. EPA's preamble should reflect this fact.

Response: The preamble states that because the rule does not allow emission increases, the EPA has determined that the proposed rule will not have disproportionately high and adverse human health or environmental effects on minority, low-income, or Tribal populations. This statement supports EPA's determination that it has complied with the terms of the Executive Order, which by its terms focuses on adverse impacts. The preamble goes on to discuss environmental justice issues more broadly by focusing on the demographic analysis that shows that that major source boilers are located in areas where minorities' share of the population living within a three-mile buffer is higher than the national average. For these same areas, the percent of the population below the poverty line is also higher than the national average. Because of the emissions reductions mandated by the rule, EPA agrees that the beneficial effects from the rule will be larger for the average minority and low income American than for all Americans.

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council

Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 68

Comment: As EPA reports, its own "demographic analysis showed that major source boilers are located in areas where minorities' share of the population living within a 3-mile buffer is higher than the national average. For these same areas, the percent of the population below the poverty line is also higher than the national average." 75 Fed. Reg. 32,048 (citing U.S. EPA, Preliminary Review of Environmental Justice Impacts (April 2010) (EPA-HQ- OAR-2002-0058-0835]).

We encourage the Agency to continue to collect facility-based emissions information, including related to high-emitting boilers as well as short-term assessments of peak emissions during abnormal operating conditions, and in areas where many industrial boilers and other HAP emissions points are located. These should be followed up with dispersion modeling to better understand human exposure at the site of the closest individual (fence-line). Information gathering and better understanding the cumulative health impacts in areas where many sources of HAP are located together (for example, near refineries) would be beneficial.

Response: EPA agrees that in some cases dispersion modeling is an appropriate component in environmental justice analytical work. The environmental justice analytical process is undergoing continual development and refinement. In future rulemakings we expect that dispersion modeling will be used when appropriate from a rulemaking and resource prospective. EPA agrees that cumulative emission studies will better inform rulemaking.

Comment: EPA Should Further Study the Effect of Biomass Emissions on Environmental Justice Issues.
The EPA should continue to consider the disproportionate impact that incinerators have on poor and minority communities. According to the EPA's webinar on national emission standards for boilers, process heaters and incinerators, 21 [Environmental Protection Agency. Background on National Emission Standards for Industrial, Commercial, and Institutional Boilers and Process Heaters; and Commercial/Industrial Solid Waste Incinerator (CISWI) Units. (2010). Retrieved from http://www.epa.gov/apti/webinars/20100609combustion.pdf] for populations living near disposal and processing facilities that may receive wastes diverted from incinerators, the results suggest that percentages of low-income and minority populations are slightly higher than national average. These results should not be used to justify avoidance of heightened standards for incinerators because low-income communities are already disproportionately affected by air pollution.22 [Ash, Michael & Boyce, James. (2009). Tracking Toxic Pollution from America's Industries and Companies to our States, Cities and Neighborhoods. Pg. 8. Retrieved from http://college.usc.edu/pere/documents/justice_in_the_air_web.pdf] The pollution from industrial

air pollution sources, such as incinerators, accumulates in places where minority populations are disproportionately affected. Id.

The EPA should do more studies to test the background levels of already existing pollution of communities affected by incinerator emissions. Background levels of air pollution in these communities are often higher than in other areas because, in general, low-income neighborhoods experience more of all forms of pollution (including air and water pollution, as well as toxic waste pollution) than do neighborhoods that maintain higher levels of income. [Morello-Frosch, Rachel. "Discrimination and the Political Economy of Environmental Inequity." Environment and Planning C: Government and Policy . 2002, Vol. 20, pp.477-496]. or example, a biomass incinerator was planned to be built in Springfield, Massachusetts, a city described as already having "an 'F' in air quality." [Mobilization for Climate Justice. (2010). Coaltion of Activists Protest Biomass Incinerators at State Global Warming Hearing in Springfield, Massachusetts. Retrieved from http://www.actforclimatejustice.org/2010/06/coalition-of-activists-protest-biomass-incinerators-at-state-global- warming-hearing-in-springfield-massachusetts/#more-2973]In fact, Springfield ranks number fourteen on the Asthma and Allergy Foundation of America's ranking of U.S. Metropolitan areas according to prevalence of asthma.25 [Human Resources. Business and Legal Resources. (2004). Asthma Group Ranks Worst Metro Areas Retrieved from http://hr.blr.com/newsAlternate.aspx?category=5&topic=66&id=9412] The EPA should use the results of studies of background emissions to strengthen regulation of emissions; for example, if an inner-city community already has high dioxin emissions, emission standards should be higher.

Response: We agree with the commenter that the consideration of disproportionate impacts on poor and minority communities is an important priority in rulemaking. We also agree with the commenter that better background data will improve the rulemaking process for all populations, including minority and low-income populations. In the environmental justice analysis completed for this rulemaking, proximity to a source was used as a surrogate for exposure to air pollutants. EPA also recognizes that the solid waste definition rule is intricately tied to the Boiler rule and that while there may be benefits associated with decreased air emissions from Boilers, there may also be disbenefits associated with diversion of waste for boiler units.

Health Based Compliance Alternatives

HBCA: Appropriateness of HBCA for Mn or HCl

Comment Excerpt Number: 119

Comment: Several options have been proposed for which EPA offered little or no justification and analysis. Some are also of doubtful legality; in particular, the clearly erroneous suggestion that EPA could establish risk-based exemptions at levels less stringent than the MACT floor. NACAA recommends that EPA avoid options that carry a substantial risk of a lawsuit that delays implementation of these important public health protections.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Arlington Public Hearing Transcript
Commenter Affiliation: See transcript for detailed list of commenters
Document Control Number: EPA-HQ-OAR-2002-0058-1779
Comment Excerpt Number: 29

Comment: We're also concerned with the exclusion of the health-based compliance alternative of the HCPA from the proposed rule. Section 112(d)(4) of the Clean Air Act establishes a mechanism for EPA to exclude facilities from certain pollution control regulations and circumstances when these facilities can demonstrate that emissions do not pose a health risk.

Using the discretionary authority under Section 112(d)(4), EPA may allow a facility to demonstrate the potential proposed risk of emissions for certain pollutants such as manganese and hydrogen chloride from the facility. If a facility can show that its emissions are below the established thresholds for levels posing a risk of human health, EPA can use these data to exclude from requirement sources from which emissions do not pose a risk.

Using HBCA at the outset would allow facilities to comply based on health-based data rather than taking the interim step of installing emission control technology.

We believe the use of the HBCA as a logical tool and that when a facility can meet a more stringent health-based standard without the necessity of expensive emission control equipment, the HBC should be allowed.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: The Clean Air Act offers U.S. EPA discretion in certain areas that can and should be used to help balance economic and environmental interests. Exercising this discretion is particularly important in difficult economic times as regulatory burdens can become the straw that breaks the economic backs of U.S. manufacturers and jeopardizes the jobs that are crucial to sustained economic recovery.

We ask that EPA exercise this Clean Air Act discretion with strength and vision to focus resources on serious health threats from air emissions and offer relief from economic burdens when such health threats are not indicated.

To relieve some of the burden for these boilers and process heaters, EPA should exercise the health threshold discretion that Congress allows under Section 112(d)(4) of the Act. Congress recognized that some pollutants are safe at low concentrations, and they allowed EPA to consider this health threshold when setting emission limits. Hydrogen chloride is a common acid and one of those compounds that is safe at low concentrations. EPA may use health risk information to test emission standards that reflect health thresholds so that we are not spending money on control equipment that is unnecessary required to protect human health.

In these strained economic times, EPA should certainly exercise its discretion to stop the regulatory burden when health is adequately protected. This can reduce environmental expenditures by two t three million dollars per unit at each of our municipal electric plants.

Response: See preamble for response to final decision on Health Based Compliance Alternative. As for economic impacts of the rule, the EPA used a standard market analysis to analyze the proposed MACT standards. The approach uses a single period multimarket partial equilibrium model to compare pre-policy market baselines with expected post-policy market outcomes. The analysis' time horizon is the intermediate run; some production factors are fixed and some are variable and is distinguished from the very short run where all factors are fixed and producers cannot adjust inputs or outputs. The intermediate time horizon allows us to capture important transitory stakeholder outcomes. Key measures in this analysis include industry-level changes in price levels, production and consumption, jobs, international trade, and social costs (changes in producer and consumer surplus). The analysis shows market responses with a very small increase in imports and a small job change.

Comment: EPA has the Clean Air Act authority through the 112(d)(4) to formulate MACT rules using a health threshold approach that would provide flexibility for sources while also ensuring the protection of public health. There is precedent for using that approach, and CIBO urges EPA to include that approach as a means to provide acid gas control in a cost-effective manner.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: EPA should establish health based emissions limitations for acid gases and manganese under § 112(d)(4).
Section 112(d)(4) authorizes EPA to set health-based emissions limitations when establishing standards for HAPs under § 112(d). Section 112(d)(4) is a powerful tool that enables EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than needed to get the job done.

The default technology-based method of setting MACT standards is a cookie cutter approach that can and does result in HAP emissions limitations that go well beyond what is needed to protect the public from HAP emissions. The clear purpose of § 112(d)(4) is to prevent this from happening. The legislative history of § 112(d)(4) is abundantly clear on this point. In formulating § 112(d)(4), Congress recognized that, "For some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment." [Footnote: S. Rep. No. 101-128 (1990) at 171]. As a result, § 112(d)(4) was provided as an alternative standard setting mechanism for HAPs "where health thresholds are well-established … and the pollutant presents no risk of other adverse health effects, including cancer…."

When the first Industrial Boiler MACT was promulgated in 2004, it included health based emissions limitations for two HAPs – hydrogen chloride ("HCl") and manganese. These health-based emissions limitations were rigorous standards that demanded accountability. They were a winner for the Agency and the public because public health would have been protected with an ample margin of safety. At the same time these standards were a winner for affected sources because the standards would not have blindly required emissions to be reduced far below the levels needed to assure that the public was protected. It was estimated at the time that these health based standards would have saved over $2 billion in compliance costs, as compared to the technology-based standards that otherwise would have applied.

In the newly proposed Industrial Boiler MACT, EPA acknowledges its authority under § 112(d)(4) to establish a health-based emissions limitation for threshold pollutants in lieu of a MACT emissions limitation. However, the Agency proposes not to establish any health based emissions limitations "[g]iven the limitations of the currently available information (i.e., the HAP mix where boilers are located, and the cumulative health impacts from co-located sources), the environmental effects of HCl, and the significant co-benefits of setting a conventional MACT standard for HCl." Nevertheless, EPA asks for comment on a wide range of issues related to the justification for setting health based emissions limitations and the method by which they should be set.

Ample scientific information supports a determination that HCl, hydrogen fluoride, hydrogen cyanide, and manganese are threshold pollutants and, thus, are eligible to be regulated under § 112(d)(4). In addition, the Agency has the technical tools and significant factual support for establishing health based emissions limitations for these HAPs that would provide the requisite ample margin of safety to health and the environment. Thus, health based emissions limitations are fully justified on scientific and technical grounds. EPA should set health based emission limitations for HAP acid gases and, like in the2004 rule, a health based emissions limit for manganese, which should be implemented in conjunction with a Total Select Metal ("TSM") standard (where the TSM standard would be an alternative to the PM surrogate, and where a "TSM less manganese" option would be provided when a source elects to comply with the health based compliance alternative for manganese).

From a legal standpoint, the statute makes clear that criteria pollutant co-benefits associated with the proposed MACT standards may not be considered in deciding whether to establish § 112(d)(4) health based emissions limitations. Also, EPA has failed to explain why the health based emissions limitations it established in the 2004 Industrial Boiler MACT and the justification provided for those limitations should now be reversed. The preamble to the newly proposed rule sets out a number of questions that might be relevant in deciding whether to establish health based emissions limitations, but merely asking questions is not a sufficient basis for reversing prior determinations adopted through notice and comment rulemaking. Thus, EPA's proposal not to set health based emissions limitations runs counter to the law and is based on an inadequate explanation of why the Agency proposes to depart from its prior approach.

Comment: EPA should allow facilities to demonstrate that emissions of certain pollutants do not pose a public health concern. A practical, health oriented standard for threshold pollutants would allow sources to demonstrate their emissions of these compounds pose no adverse risk. The Clean Air Act in §112(d)(4), expressly contemplates the use of such an approach, which can be implemented without sacrificing risk reduction benefits. A health threshold standard is critical to the future viability of biomass and other boiler fuels. EPA has indicated to stakeholders that this alternative will not be part of the proposed rule language. EPA should revisit this thinking and make the health threshold standard an integral part of its proposed Rules and allow an opportunity for public comment on this approach.

Comment: Health-Based Compliance Alternative. There needs to be a Health-Based Compliance Alternative (HBCA) for HCl. As proposed, certain of the Maine Mill boilers would be required to install a scrubber to remove small concentrations of HCl to meet the MACT emissions limits even though there is no health issue. This will result in a huge capital cost of millions of dollars per boiler for no health benefit. EPA is authorized to use HBCAs and there is no point in making the HCl standard tighter and more costly to control if there is no health related issue.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: APPA also supports health-based emissions limits ("HBELs") as EPA proposed and supported for the Boiler MACT source category under the 2004 Boiler MACT rule. EPA has clear authority to adopt HBELs under section CAA 112(d)(4) for pollutants "for which a health threshold has been established." As EPA previously acknowledged, a threshold below which no adverse effects are observed has been established for both HCl and manganese. In 2004, EPA concluded that health and safety were protected with an ample margin of safety when the concentrations of HCl or manganese at the point of exposure were below the threshold for health effects. These safe concentrations of HCl and Mn can be assured, as was proposed in 2004, when facilities meet designated stack heights and fenceline distances sufficient to keep HCl and Mn below risk thresholds at the point of exposure. EPA has arbitrarily eliminated HBELs from the proposed rule without providing an adequate explanation for its about-face.

Comment Excerpt Number: 6

Comment: Use Health Based Compliance Alternatives. The EPA should allow the use of health-based compliance alternatives that is based upon facility specific emissions of which is modeled against reference concentrations provided by EPA using a health index. This alternative would ensure protection of health and the environment and provide a potentially more cost effective solution in some cases.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Document Control Number: EPA-HQ-OAR-2002-0058-2418.1
Comment Excerpt Number: 6

Comment: Secondly, the EPA should exercise its discretion under section 112(d)(4) of the Clean Air Act to set health-based emission limits. Doing so would eliminate the need for additional controls where threshold pollutants are now low enough to be safe. We at Stoltze agree with AF&PA that the EPA should make the health threshold an integral part of its final rule.

Comment Excerpt Number: 10

Comment: The Maine DEP understands that EPA's previous attempts to provide health-based compliance alternatives in standards established under Section 112 have been rejected by the courts. We believe, however, that EPA's proposed standards for hydrochloric acid (HCl) exceed the levels necessary to protect public health and will create an unnecessary compliance burden for affected units. We recommend that EPA apply the provisions of Section 112(d)(4) to the extent possible to establish a more appropriate scheme for HCl emission reductions. We would also suggest EPA consider the application of this provision to the regulation of non-mercury metal HAP as an alternative to compliance with the proposed PM standard.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Jack Carter
Commenter Affiliation: Weyerhaeuser Company
Document Control Number: EPA-HQ-OAR-2002-0058-2797.1
Comment Excerpt Number: 12

Comment: Weyerhaeuser urges EPA to reverse its new position and provide health-based compliance alternatives for HCl and for manganese. (We note for manganese this also necessitates that EPA reintroduce a Total Selected Metals limit as an alternative to the PM surrogate limit for HAP metals.) When the original Boiler MACT was promulgated in 2004, it included "Health Based Compliance Alternatives" (HBCA) as emissions limitations for HCl and manganese. Weyerhaeuser found these alternatives would have been a significant cost reduction factor that still met the CAA goals of reducing health and environmental risk. At that time we intended to employ the HBCA for one or both of the target HAPs at about one-third of our then-existing portfolio of mills. As the AWC and AF&PA comments detail, these health-based emissions limitations were rigorous standards that demanded accountability and were a win-win-win, for the EPA and the public because public health would have been protected with an ample margin of safety, and for affected sources because the standards would not have blindly required emissions to be reduced far below the levels needed to assure that the public was protected.

Even though in the preamble to the proposed Boiler MACT EPA acknowledges its authority under CAA §112(d)(4) to establish a health-based emissions limitation for threshold pollutants in lieu of a MACT emissions limitation, the Agency declined to do so. However, EPA asks for comment on issues related to the justification for setting health based emissions limitations and the method by which they should be set. As proposed, we believe the extreme cost burdens the rule will impose on us and on the industrial boiler owners of the Nation, justify that EPA use the available resources in its toolkit to reduce those costs as long as the health objective Congress attached to this technology-based regulation is maintained. We believe that can be done, and refer EPA to the detailed health and technical justifications for HCL and manganese health-based emission limitations in the AWC and AF&PA comments. We strongly urge EPA to use its discretion to put these alternatives in place.

Comment: Health Based Compliance Alternative (HBCA) for HCl
The University believes the HBCA to be a reasonable and responsible compliance alternative. The University submitted its HBCA Eligibility Demonstration in September of 2006. That submission required the University to perform additional stack tests and to engage a consulting firm to compile the documentation. That report showed the University to be well below the standard in the look up chart for our stack height and distance to the property line. The University has not seen any
documentation that would discount the validity of this alternative. The University believes that the reasoning for its inclusion in the original publication is sound and has yet to be successfully challenged.

Comment Excerpt Number: 27

Comment: EPA could avoid this concern for many facilities by adopting standards that include a health-based emission limitation, as previously discussed. This would reduce the need to install controls to meet limitations for HCl and metals/PM. If EPA does so, many wood products facilities will not face the problem of a new and potentially high volume process wastewater that is difficult to manage and not possible to permit and discharge from the site. For those wood products facilities that cannot take advantage of a health-based emission limitation, however, the technology EPA has assumed would be available to meet HCl and other limits may still in fact be unavailable due to the constraints on wastewater discharges. To remedy the problem at wood products facilities where this occurs, EPA should adopt work practice standards for control of HCl and other pollutants for which a wet control device would be needed, rather than requiring compliance with numerical emission limitations.

Comment Excerpt Number: 28

Comment: AF&PA supports the inclusion of risk-based limits for HCl as a means of minimizing investments that would do little in terms of reducing risk from boiler emissions. The submittal includes two charts that (1) industrial liquid and wood fired boilers do not emit significant amounts of HCl [Footnote: EPA's 2005 National Emissions Inventory, http://www.epa.gov/ttn/chief/net/2005inventory.html], and (2) biomass boilers have inherently low HCl emissions and the top performers do not employ HCl control technologies. Given the nation's need to diversify fuel supplies, EPA should encourage use of domestic, renewable, carbon neutral fuels such as wood residuals, rather than create regulatory programs that discourage their use, especially when their use can be demonstrated not to pose a risk to human health and the environment.

Biomass boilers are not large sources of HCl, and top performers do not employ wet scrubbers to control HCl emissions from biomass. As demonstrated in the chart below, 8 of the 13 top performers for Biomass HCl emissions have dry particulate controls. The units with scrubbers are co-firing sulfur containing fuels such as oil and TDF or are burning sulfur containing process gases.

For liquid boiler top performers, the same issues are present. All but one of the boilers in the liquid HCl floor has no control; one boiler burning residual oil has a fabric filter, which provides no HCl control. One boiler in the liquid mercury floor has an ESP, one has a multiclone, and the rest have no HAP emissions controls. Again, the liquid boiler floors for the fuel based HAP are being driven by fuels that have low chloride and mercury contents, not by boilers employing any type of mercury or HCl emissions controls. It does not make sense to require controls on boilers burning a clean liquid fuel such as distillate fuel oil that do not happen to contain the extremely low chloride or mercury contents that the floor boilers do.

Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 37

Comment: EPA has solicited comment on whether the agency should adopt "risk-based" exemptions for manganese and HCl. Section 112(d)(4) of the CAA provides:
With respect to pollutants for which a health threshold has been established, the Administrator may consider such threshold level, with an ample margin of safety, when establishing emission standards under this subsection.

After careful review, NACAA has concluded that these exemptions are not authorized by the CAA and are not in the public interest. The factual predicate for the use of section 112(d)(4) for acid gas HAP and metal HAPs – the establishment of a health threshold for each of these pollutants – has not been met. Congress authorized risk-based standards only “where health thresholds are well-established...and the pollutant presents no risk of other health effects, including cancer, for which no threshold can be established....”[63 S. Rep. No. 228, 101st Cong. 1st Session, (December 20, 1989), reprinted in A Legislative History of the Clean Air Act Amendments of 1990 (Comm. Print 1993), at 8511.]

Comment Excerpt Number: 39

Comment: On August 6, 2010, EPA adopted a NSPS for Portland Cement plants. In its final rule EPA specifically rejected adoption of risk-based exemptions for HCl and manganese, making many of the points identified above and also relying on the benefits associated with the co-removal of SO2. There are no differences sufficient to warrant a reversal of that decision in this standard. Moreover, EPA has not identified a proposal for an exemption with sufficient specificity to allow for meaningful comment for a final rule. Finally, there is no record sufficient to support such a proposal and insufficient time under the applicable statutory and judicial deadlines to develop such a proposal and rulemaking record.

Comment: EPA may not lawfully invoke Section 112(d)(4) health risk-based alternatives to MACT floor setting for ICIBPH in this rulemaking.

EPA sets numerical MACT floor limits for acid gases (chlorine (Cl2), hydrogen chloride (HCl), hydrogen fluoride (HF), and hydrogen cynanide (HCN)) emitted by industrial, commercial and institutional boilers through limits on HCl as a surrogate for those ‘non-metal inorganic HAPs’. While we have serious concerns with the Agency’s surrogacy decision, as outlined above, commenters do applaud EPA’s decision to set MACT-based standards for acid gases. The Agency also considered, in the alternative, whether to “exercise [its] discretionary authority to establish health-based emission standards under CAA section 112(d)(4) for HCl and each of the other relevant HAP acid gases – Cl2, HF, and HCN”. 75 Fed. Reg. 32,010. EPA specifically asks several questions pertaining to the limits on the exercise of its § 112(d)(4) authority, and seeks comment on that point as well as soliciting further technical information about the health effects of these pollutants. We offer some responses to those questions here. Our responses should not be taken to suggest in any way, however, that we agree EPA is authorized to exercise the very limited authority it has under §112(d)(4) in this rulemaking.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: The Statute Does Not Permit EPA to Establish Standards under § 112(d)(4) for any HAP for which there is no Existing Health Threshold Based on No Observable Adverse Effects

CAA section 112(d)(4) states that "[w]ith respect to pollutants for which a health threshold has been established, the Administrator may consider such threshold level, with an ample margin of safety, when establishing emission standards under this subsection." 42 U.S.C. § 7412(d)(4) (emphasis added). The use of the phrase "has been established," shows that Congress did not intend for this provision to be used by EPA to spend time and resources during the MACT standard-setting exercise to figure out whether a given pollutant might have a health threshold, but may rely on this authority only where an accepted threshold already is in existence. See Brief for Respondent Environmental Protection Agency in National Lime Ass'n v. EPA, (July 14, 2000). That health threshold, at a minimum must be based on the "no observable effects level" for any health endpoint associated with that pollutant. See S. Rep. No. 101-228 at 171 (1990).

Section 112(d)(4) was included in the 1990 ground up revisions to the air toxics requirements of the Clean Air Act. Prior to 1990, the CAA required individual HAP listing and standard setting, based on public health protection with "an ample margin of safety." CAA of 1970 §112(b)(1)(B), P. Law 91-604 (amended in 1990). The 1990 revisions, of course, included a list of HAPs to be regulated and required that EPA set technology-based standards for those HAPs for listed industries. Section 112(d)(4), as finalized, authorized the Agency to "consider" an "established " health threshold [Footnote: In fact, the Senate Report describes the prerequisite as a "well-established" health threshold. See S. Rep. 101-228 at 171.] in setting such standards. By contrast, an earlier draft of the CAAA would have made the authority to set a health-based standard contingent on a finding that a threshold "can be established" [Footnote: 3 1990 Legislative History at 4425.] a forward looking construct that would accommodate investigation and establishment of the threshold as part of the MACT standard setting exercise, in a way that the final enacted language of §112(d)(4) does not.

Moreover, the legislative history requires that any established health threshold that might form the basis for a health-based alternative standard must be based on the " 'no observable [adverse] effects level' (NOAEL) below which human exposure is presumably 'safe'." S. Rep. No. 101-

228 at 171 (1990). As will be shown below, there is no such established health threshold currently for HCl, or for any of the other acid gases (non-metal inorganic HAPs) EPA identifies as emitted by industrial boilers. As a threshold matter, then, section 112(d)(4) authority to set an alternative, health-based standard for HCl is simply not available to the Agency here, because as shown below, there is no established accepted health threshold for HCl, or the other acid gases, as Congress intended that concept to be understood. In particular, as EPA has admitted, the agency does not know whether or not HCl causes cancer. 71 Fed. Reg. 76,542, 76,553 (Dec. 20, 2006) ("The data are inadequate to make a determination as to whether HCl is carcinogenic in either humans or animals, so EPA has not developed an assessment for the carcinogenicity of HCl."). Obviously, if EPA does not even know whether HCl causes cancer, the agency has not identified an established health threshold below which HCl does not cause cancer. For this reason alone, EPA cannot invoke § 112(d)(4) with respect to HCl.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council
Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 58

Comment: EPA Is Not Authorized to Set §112(d)(4) Standards Based on A Surrogate Pollutant.

Because EPA must base any §112(d)(4) health based standard on the "no observable adverse effects level, it may not rely on a surrogate in evaluating or setting risk based standards under §112(d)(4). EPA agrees it would not be an appropriate surrogate for a health-based standard. It is well established that when setting §112(d) MACT-based standards, EPA must set standards for each HAP emitted by a category or subcategory of sources. National Lime Ass'n v. EPA, 233 F.3d 625, 633-34 (D.C. Cir. 2000). Similarly, if the Agency invokes §112(d)(4) authority to consider setting a health-based alternative standard, the Agency must conduct that evaluation on a pollutant-specific basis "with respect to pollutants" for which a health threshold is established. [See 75 Fed. Reg. 32,030 at n. 16.]

Even if HCl could reasonably serve as a surrogate for the other acid gases under a technology-based MACT standard (a point which we do not concede), it cannot be a surrogate in health based standard setting. As shown in Table VI-1 below, for HCl, CL2, and HF, the primary health endpoint is respiratory irritation. [See submittal for table VI-1.] For HCN, however, the primary health endpoint is neurological. Indeed, EPA notes that "[t]hese gases (for example HCN) can act on biological organisms in a ifferent manner than HCl, and each of the acid gases affects human health with a different dose-response relationship." Id. It is inappropriate to select one acid gas (HCl) with one health endpoint to serve as a surrogate for another acid gas (HCN) with a different health endpoint.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 92

Comment: In order to provide additional compliance flexibility for sources, AF&PA also recommends EPA includes a health-based total selected metals (TSM) compliance alternative along with the TSM emission limit option. Similar to the approach EPA took in the 2004 Boiler MACT rule, in the health-based TSM compliance alternative option, manganese emissions would not be included in the TSM calculation if facility emissions of manganese were below health-based thresholds established using either a lookup table or site specific modeling and risk analysis. Combustion of biomass fuels results in higher ratio of manganese to TSM than combustion of fossil fuels, and as stated in the section of our comments that addresses health-based emission limits, manganese is a threshold pollutant and appropriate for consideration in a health-based regulatory approach. Increased use of renewable fuels such as woody biomass is part of our national energy and climate policy. Providing this alternate TSM compliance strategy will provide a compliance mechanism that will not disadvantage the use of wood fuel and potentially create the unintended consequence of replacing woody biomass fuel with fossil fuel.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 127

Comment: The default technology-based method of setting MACT standards is a cookie cutter approach that can and does result in HAP emissions limitations that go well beyond what is needed to protect the public from HAP emissions. The clear purpose of § 112(d)(4) is to prevent this from happening. The legislative history of § 112(d)(4) is abundantly clear on this point. In formulating § 112(d)(4), Congress recognized that, "For some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment." S. Rep. No. 101-228 (1990) at 171. As a result, § 112(d)(4) was provided as an alternative standard setting mechanism for HAPs "where health thresholds are well-established … and the pollutant presents no risk of other adverse health effects, including cancer…." Id.

The first Industrial Boiler MACT was overturned by the D.C. Circuit, but on grounds unrelated to the health- based emissions limitations. Notably, in defending the health- based emissions limitations, the Department of Justice concluded that, "Environmental Petitioners' claim that the statute precludes EPA from establishing alternative standards for threshold pollutants (which petitioners mischaracterize as an exemption) is meritless." Final Brief For Respondent United States Environmental Protection Agency, D.C. Cir. Case No. 04-1385 (Dec. 4, 2006) at 53-54

Giving full consideration to the use of health-based standards is particularly important in the wake of the series of decisions from the D.C. Circuit that have progressively limited EPA's discretion to make common-sense decisions when setting MACT standards under § 112. EPA's authority to set health- based standards under § 112(d)(4) is unassailable. For appropriate HAPs and where the relevant facts substantiate its use, EPA can set health-based standards with full confidence that they will survive judicial review.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)

Comment Excerpt Number: 128

Comment: The work that EPA performed in support of the HBELs included in the 2004 rule demonstrates that the proposed standards are far more stringent than needed to assure the protection of public health with an ample margin of safety. The costs and burdens on affected sources and the degree of control needed to provide adequate health and environmental protection are both key factors that should be considered by the Agency in deciding whether to adopt HBELs in the Industrial Boiler MACT.

In the proposed rule, EPA completely ignores these factors. The Agency's discussion of HBELs includes no assessment whatsoever of the costs that might be avoided by adopting HBELs for HCl or manganese. As to potential effects on health or environment, EPA simply raises implementation questions and asserts a lack of information to resolve the questions. Such an approach is facially inadequate in light of the extensive policy, scientific, and technical assessment developed in support of the HBELs in the 2004 Industrial Boiler MACT standard.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: A health protective HBEL under CAA 112(d)(4) could take a number of forms. For example, a tiered approach could be developed where a conservative look-up table provides HCl equivalent emission rate thresholds for various source-receptor combinations. If the look-up table is not viable, then site-specific modeling following established U.S. EPA risk assessment guidance could be performed to establish an appropriate HBEL. For example, detailed dispersion modeling using source specific stack parameters and receptor locations could be used to establish appropriate HBELs. Variability in emissions could be addressed by consideration of variability in fuel consumption and fuel content. A robust statistical method could be applied to assure conservatism with a reasonable level of certainty, such as the 95th percentile commonly applied by EPA. Alternatively, limits for HCl and other pollutants established in air permits could be proposed for use in lieu of establishing separate HBELs.

Response: See preamble for response to final decision on Health Based Compliance Alternative. See preamble for discussion of MACT floor methodologies and statistical variability analysis.

Comment: The Chamber questions the stringent limits when the results from EPA's air toxics at school monitoring program that was conducted at Chicora Elementary School located in North Charleston, South Carolina showed results from HAP pollutants well below the screening values established by EPA. The recent monitoring at the school shows that stringent reductions imposed by the proposed Boiler MACT standard are not necessary to meet health-based compliance concentrations.

The Chamber offers comments and recommendations on the following key areas of the proposed rule.

Comment: EPA should allow facilities to demonstrate that emissions of certain pollutants do not pose a public health concern. A practical health oriented standard for threshold pollutants like hydrogen chloride and manganese would allow sources to demonstrate their emissions of these compounds pose no adverse risk. The Clean Air Act in §112(d) (4), expressly contemplates the use of such an approach which can be implemented without sacrificing risk reduction benefits. A health threshold standard is critical to the future viability of biomass and other boilers. EPA should make the health threshold standard an integral part of its final rule.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: When the first Industrial Boiler MACT was promulgated in 2004, it included health based emissions limitations for two HAPs — hydrogen chloride ("HCI") and manganese. These health-based emissions limitations were rigorous standards that demanded accountability. They were a winner for the Agency and the public because public health would have been protected with an ample margin of safety. At the same time these standards were a winner for affected sources because the standards would not have blindly required emissions to be reduced far below the levels needed to assure that the public was protected. It was estimated at the time that these health based standards would have saved over $2 billion in compliance costs, as compared to the technology-based standards that otherwise would have applied. The Chamber requests EPA reconsider their decision not to include these health-based limitations in the newly proposed Industrial Boiler MACT.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: The Agency has the authority to establish a health-based standard for HCI.

As EPA knows, the Clean Air Act Amendments of 1990 substantially revised the Nation's program to control hazardous air pollutants. In these amendments, Congress split the program into two phases. In the first phase, the Agency requires control commensurate with "the maximum degree of reduction in emissions" being achieved by the best controlled sources. 42 USC 7412(d)(2) and (3). This phase is commonly referred to as the technology-standard phase. See e.g., 1990 Leg. Hist. at 862, 875, 876, 950, 1029, 1062,1079. In the second phase, EPA is to examine the amount of risk that remains to human health and the environment, and impose further controls if necessary to protect human health with an ample margin of safety, and prevent adverse environmental consequences. 42 USC 7412(f).

This shift to an initial technology-based program was not absolute, however. Congress authorized EPA to use a risk-based approach during the technology-based phase where further regulation was not necessary from a risk standpoint. Consequently, EPA is allowed to delist an entire source category or subcategory, if none of the sources in it emit hazardous air pollutants that create a risk greater than 1 in one million excess cancer cases. 42 USC § 7412(c)(9).

Another risk-based component was enacted in § 112(d)(4). 42 USC § 7412(d)(4). Since at least 1997, EPA has recognized that section 112(d)(4) authorized the Agency to set risk-based emission standards in lieu of technology-based standards. As EPA wrote in a Federal Register notice, "Congress provided in section 112(d)(4) that EPA could, at its discretion, develop riSk-based standards for HAP ‘for which a health threshold has been established,’ provided that the standard achieves,an ‘ample margin of safety.’" 62 FR 33625, 33631 (June 20, 1997). [Footnote: EPA then proceeded to use this authority in the first Plywood MACT. See 63 Fed. Reg. 18754, 18765 (April 15, 1998) (Proposed National Emission Standards for Hazardous Air Pollutants; Proposed Standards for Hazardous Air Pollutants From Chemical Recovery Combustion Sources at Kraft, Soda, Sulfite, and Stand-Alone Semichernical Pulp Mills), finalized at 66 FR 3180 (January 12, 2001).]

Based on the legislative history that clarifies Congressional intent, this ‘ interpretation is clearly correct. The Senate Report wrote,

To avoid expenditures by regulated entities which secure no public health or environmental benefit, the Administrator is given discretionary authority to consider the evidence for a health threshold higher than MACT at the time the standard is under review. The Administrator is not required to take such factors into account; that would jeopardize the standard-setting schedule imposed under this section with the kind of lengthy study and debate that has crippled the current program. But where health thresholds are well established, for instance in the case of ammonia, and the pollutant presents no risk of other adverse health effects, including cancer, for which no threshold, can be established, the Administrator may use the threshold with an ample margin of safety (and not considering cost) to set emissions limitations for sources in the category or subcategory. Employing, a health threshold or safety level rather than, the MACT criteria to set standards shall not result in adverse environmental effects which would otherwise be reduced or eliminated.

1990 Leg. Hist. 8511, S. Rep. No 228, 101st Cong. Sess. 171 (1990). See also 1990 Leg. Hist. 8516 (Administrator authorized to use threshold level "in lieu of more stringent ‘best technology’ requirements."). Thus, EPA clearly has the authority to set a risk-based standard.

EPA cannot set a risk-based standard for just any HAP, however. It must be a "threshold pollutant." As the Agency noted in the preamble, HCI is a health threshold pollutant for the purpose of section 112(d)(4). 75 FR 32030.

Even though EPA states that there is no evidence that HCI is a carcinogen (75 FR 32030), some may argue that HCI does not meet Congressional intent for defining threshold pollutant because it has not, been conclusively shown to be non-carcinogenic. That is not necessary according to Congress. As quoted above, Congress explained that ammonia was, a HAP with a "Well-established" threshold for which EPA could set a risk-based standard. A comparison of the IRIS information relating to carcinogenicity for ammonia and HCI shows striking similarities: the information for both ammonia and HCI contains the same notation relating to carcinogenicity, i.e., it has "not undergone a complete evaluation and determination under US EPA’s IRIS program for evidence of human carcinogenic potential." Compare http://www.epasiovincea/iris/subst/0422.htm (Ammonia) with http://www.epa.govincea/iris/substiO396.htm (HCI) (viewed August 12, 2010). There are other similarities as well: i.e., EPA only looked at respiratory effects of both HCI and ammonia, and the RfC for ammonia appears to be based on a LOAEL, not a NOAEL — just like HCI.

In short, EPA has the authority to set a health-based standard for HCI under §112(d)(4). To believe that EPA must make a positive finding of absolutely no cancer risk, i.e., prove a negative, renders this provision a near nullity and belies both the scientific process and Congressional intent.

Comment: Considering the significant impact of this proposed regulation on industry ($2.8 billion from Table 11, 75 FR 32038) the HBCA approach to determine compliance offers the opportunity to achieve the EPA's air quality improvement goals with greater flexibility to the regulated facilities (many of which have unique characteristics and configurations) and to reduced implementation costs for sites to which the HBCA would apply. Such an approach appears permissible according to §112(d)(4) of the Clean Air Act, as detailed in the comments filed by the American Forest & Paper Association.

Comment: One issue that often arises when considering risk-based standards is whether EPA has authority under Section 112 to establish an exposure based emission limit. The concern seems to be that some stakeholders construe the Act's statutory provisions as requiring uniform emission limitations at all facilities, rather than emissions that are measured at places away from the source and that vary from facility to facility. CRWI does not see any legal impediment to establishing exposure based limits.

First, under Section 112, EPA has authority to establish "emission standards." Emission standards are defined to be a requirement established by the State or the Administrator which limits the quantity, rate or concentration of emissions of air pollutants on a continuous basis . . .

to assure continuous emission reduction, and any design, equipment, work prktice or operational standard promulgated under this chapter.

EPA's altemate risk-based emission standard will limit the quantity, rate or concentration of the emissions using operating parameter limitations, or OPLs. These will limit the quantity, rate or concentration of emission. They will be measured at the facility, not at the point of exposure.

Finally, the limitations that EPA is establishing are uniform. They uniformly protect the individual most exposed to emission levels no higher than a hazard index of 1.0.

Thus, CRWI suggests that EPA follow, the process used for Subpart EEE and allow facilities to make a site-specific showing that their emissions will be protective with an ample margin of safety. It will be the responsibility of the facility to make that showing and the permitting authority would have the responsibility to review and approve that site-specific demonstration.

Comment: EPA should use its authority under § 112(d)(4) to establish health-based standards for HCl and other acid gases. Section 112(d)(4) gives EPA explicit authority to consider health threshold levels, "with an ample margin of safety," when establishing MACT standards for pollutants for which a health threshold has been established. The purpose of this section is to "avoid regulatory costs which would be without public health benefit." S. Rep. No. 101-228, at 148 (1989).

EPA has used this authority in several situations and should do so again in this instance. In fact, the original NESHAP for commercial and industrial boilers and process heaters contained alternative compliance requirements, establishing health-based emissions standards for HCl pursuant to EPA's § 112(d)(4) authority. See 69 Fed. Reg. 55,227, 55,240 (Sept. 12, 2004). EPA has previously determined that HCl has an established health threshold and is not a human carcinogen. See 67 Fed. Reg. 78,046, 78,057 (Dec. 20, 2002) (NESHAP for Lime Manufacturing; EPA exercised its authority under § 112(d)(4) and determined that "further control of HCl emissions from lime manufacturing plants [was] not necessary."); see also 63 Fed. Reg. 18,754, 18,765 (April 15, 1998) (NESHAP for Pulp and Paper; EPA exercised its discretion under § 112(d)(4) and proposed "not to regulate HCl emissions from recovery furnaces."). EPA should again exercise its authority to set health-based rather than technology-based limits where no significant risks to human health are present.

Comment: Ample scientific information supports a determination that HCl, hydrogen fluoride, hydrogen cyanide, and manganese are threshold pollutants and, thus, are eligible to be regulated under §112(d)(4). In addition, EPA has the technical tools and significant factual support for establishing health based emissions limitations for these HAPs that would provide the requisite ample margin of safety to health and the environment. Thus, health based emissions limitations are fully justified on scientific and technical grounds.

EPA should set health based emission limitations for HAP acid gases and, as in the 2004 rule, a health based emissions limit for manganese, which should be implemented in conjunction with a Total Select Metal (“TSM”) standard (where the TSM standard would be an alternative to the PM surrogate, and where a “TSM less manganese” option would be provided when a source elects to comply with the health based compliance alternative for manganese).

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: Health Based Alternative.
EPA is authorized by Section 112(d)(4) of the CAA to consider whether emissions from a regulated HAP could affect human health when it establishes MACT standards for a particular category. In doing so, EPA can consider limiting the burden on regulated sources with HAP emissions that pose little or no health hazard by implementing a Health Based Compliance Alternative (HBCA). The HBCA constitutes a real, enforceable emission standard under the law. The HBCA is not an exemption, but rather a compliance option tied to enforceable standards. Sources governed by the HBCA must achieve specific health-based emission standards set by EPA. If these standards are not met, the source must meet the "regular" Boiler MACT compliance requirements. This constitutes a strict standard for a source that chooses the HBCA route to compliance, and should in no way be viewed as an exemption from the Boiler MACT.

The CAA’s multiple compliance option structure, which contemplates application of an HBCA, enables EPA to fulfill its statutory requirement to establish emission standards for the entire Industrial/Commercial/Institutional Boilers and Process Heaters category. Whether a source is governed by the HBCA or the "regular" approach, every source in the category will be subject to an emission standard as required by the statute. EPA established this system of multiple compliance options by relying upon its clear legal authority to include HBCA for threshold pollutants as an option for compliance with the Boiler MACT.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 199

Comment: The Absence of a Health Based Compliance Alternative Directly Impacts CIBO Members.
CIBO members operate boilers that burn every conceivable fuel source, including the full range of available coals, wood, natural gas, biomass, coal refuse, and other fuels. These boilers vary greatly in their design, capacities, fuel requirements, air emission characteristics and air pollution control equipment. Some plants use anywhere from two to six different sources of fuel in order to ensure reliability of supply, maintain proper operation, attempt to minimize costs and maintain the viability of production facilities to remain competitive and operational in globally competitive markets.

CIBO members in the manufacturing sector face unprecedented pressure to remain competitive in the world market. Uncertainties such as inflexibility in meeting regulatory standards in the U.S. create additional pressure on companies to shift production overseas or to close down altogether. The HBCA provides CIBO members with compliance flexibility that could prove critical to a company’s decision to continue operating a particular facility or to forego raising customer prices. EPA’s failure to include an HBCA substantially narrows the available options to comply with the MACT standard, and places a further strain on the equipment of CIBO’s members and on the consulting engineering resources that are needed to assist industry in meeting the timelines for compliance.

Document Control Number: EPA-HQ-OAR-2002-0058-2755.1
Comment Excerpt Number: 1

Comment: EPA should establish health based emissions limitations under section 11 2(d)(4) when appropriate.

EPA has requested comments on whether the agency should impose a health-based standard under section 1 12(d)(4) for HCl and other acid gas emissions. Section 112(d)(4) authorizes EPA to set health-based emissions limitations when establishing standards for HAPs under section 112(d). Section 1 12(d)(4) allows EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than needed to protect human health.

The default technology-based method of setting MACT standards is an approach that can and does result in HAP emissions limitations that go well beyond what is needed to protect the public. The clear purpose of section 112(d)(4) is to prevent the promulgation of unduly stringent emission limits simply for the sake of regulation. The legislative history of section 112(d)(4) is clear on this point. In formulating section 112(d)(4), Congress recognized that, “For some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment.” [. Rep. No. 101-228 (1990) at 171.] As a result, section 112(d)(4) was provided as an alternative standard setting mechanism for HAPs “where health thresholds are well-established ... and the pollutant presents no risk of other adverse health effects, including cancer.

Section 112(d)(4)’s inclusion in the 1990 CAA Amendments indicates a congressional intent to retain the health endpoint of the original section 112 – protection of public health with an ample margin of safety. [The ample margin of safety concept also underlies the current residual risk provisions of CAA section 112(f).] If the emissions of a given HAP from all sources in a source category are at a level where public health is protected with an ample margin of safety, then there is no practical need for or benefit from further regulation. EPA should set health-base standards under section 1 12(d)(4) when facts support its use.

Comment: Clean Air Act Section 112(d)(4) authorizes EPA to set health-based emissions limitations when establishing standards for HAPs under § 112(d). Section 112(d)(4) is a powerful tool that enables EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than needed to get the job done. The default approach used by EPA to set the proposed standards is a cookie cutter approach that can and does result in HAP emissions limitations that go well beyond what is needed to protect the public from HAP emissions. The clear purpose of § 112(d)(4) is to prevent this from happening.

When the first Industrial Boiler MACT was promulgated in 2004, it included health-based emissions limitations for two HAPs — hydrogen chloride ("HCl") and manganese. These health-based emissions limitations were rigorous standards that demanded accountability. They were a winner for the Agency and the public because public health would have been protected with an ample margin of safety. At the same time these standards were a winner for affected sources because the standards would not have blindly required emissions to be reduced far below the levels needed to assure that the public was protected.

EPA should set health-based emission limitations for HAP acid gases and, like in the 2004 rule, a health-based emissions limit for manganese, which should be implemented in conjunction with a Total Select Metal ("TSM") standard (where the TSM standard would be an alternative to the PM surrogate, and where a "TSM less manganese" option would be provided when a source elects to comply with the health-based compliance alternative for manganese).

Document Control Number: EPA-HQ-OAR-2002-0058-2916.1
Comment Excerpt Number: 2

Comment: EPA Should Have Adopted A Health-Based Compliance Alternative (HBCA)Which Provides Alternative Emission Limits for Threshold Chemicals
EPA has proposed not to exercise its discretion to use section 112(d)(4) to establish a health-based emission standard for HCL and manganese, despite acknowledging that it has such discretion under the Clean Air Act. For its part, the Boiler MACT Panel Report recommends that "EPA adopt the HBCA as a regulatory flexibility option for the Boiler MACT rulemaking. The panel recognizes, however, that EPA has concerns about its legal authority to provide and HBCA under the Clean Air Act, and EPA may ultimately determine that this flexibility is inconsistent with the Clean Air Act." [SBAR Panel Report at 23.]
In fact, EPA has not determined that the 112(d)(4) discretion is inconsistent with the Clean Air Act, nor has it determined that a health-based emission standard cannot be developed for HCl. Rather, EPA simply takes that position that it does have sufficient information to establish an HCl standard under section 112(d)(4), and EPA failed to adequately explain why it is failing to reaffirm the HBCA approach it adopted in the 2004 final boiler rule. Further, the Department of

Justice, stated in its brief defending the previous use of 112(d)(4) in the boiler rule, that claims that the statute precludes the adoption of alternative standards was “meritless.” [Environmental Petitioner’s claim that the statute precludes EPA from establishing alternative standards for threshold pollutants (which petitioners mischaracterize as an exemption) is meritless. Final Brief For Respondent United States EPA, D.C. Cir Case No. 04-1385 (December 4, 2006) at 53-54.] Significantly, small entity representatives commented during the Panel that “adopting an HBCA . . . would be the most important step EPA could take to mitigate the serious financial harm the Boiler MACT would otherwise inflict on small entities . . . [t]herefore, HBCA should be a critical component of any future rule to lesson impact on small entities.” [SBAR Panel Report at 23.] Because EPA has not determined that an HCl HBCA is inconsistent with the Clean Air Act, EPA should have followed the unanimous Panel recommendation and adopted the HBCA for HCl and manganese as a regulatory flexibility option. Such an alternative alone is widely expected to save substantial capital and annual costs, and prevent a significant number of plant shutdowns and job losses, with no detriment to environmental protection. [[In the 2004 final Boiler rule, vacated for other reasons, it was estimated that the HBCA approach saved over $2 billion. See American Forest and Paper Association comments filed August 23, 2010 in this docket. The AF&PA SER comments estimated capital savings in excess of $100 million just for the small facilities in the pulp & paper sector. SBAR Panel Report at 41. It was disappointing that EPA’s discussion of the alternative approach provided no assessment of what costs might be saved by this alternative approach, and that might explain why this alternative was not more seriously considered.]

Comment: EPA Has Ample Authority to Adopt Health-Based Emissions Limitations for Boilers.
Section 112(d)(4) is a powerful tool that enables EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than necessary.
As EPA explains in the Proposed Rule, section 112(d) generally requires MACT emissions limitations to be set at a level that reflects the performance of the better performing sources in the given source category or subcategory. Section 112(d)(4) provides an alternative to this basic

approach for pollutants for which a health threshold has been established. For such pollutants, section 112(d)(4) authorizes ITA to "consider such threshold levels, with an ample margin of safety, when establishing emission standards" under section 112(d).
The default technology-based method of setting MACT standards is a cookie cutter approach that results in HAP emissions limitations that sometimes go well beyond what is needed to protect the public from HAP emissions. The clear purpose of section 112(d)(4) is to prevent this from happening. The legislative history of section 112(d)(4) is abundantly clear on this point. In formulating section 112(d)(4), Congress recognized that "[for some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment." S. REP. No. 101-228 (1990) at 171. As a result, section 112(d)(4) was provided as an alternative standard setting mechanism for HAPs "where health thresholds are well-established . . . and the pollutant presents no risk of other adverse health effects, including cancer. . . /d. [Footnote: AMP supports the more detailed scientific analysis of HBELs and the health threshold determinations for HCl, chlorine, hydrogen fluoride, and hydrogen cyanide ("acid gases") are included in the American Forest and Paper Association comments to this rule.]
The first Boiler MACT rule was overturned by the D.C. Circuit but on grounds unrelated to the health-based emissions limitations. Notably, in defending the health-based emissions limitations, the Department of Justice concluded that "Environmental Petitioners' claim that the statute precludes EPA from establishing alternative standards for threshold pollutants (which petitioners mischaracterize as an exemption) is meritless." Final Brief For Respondent United States Environmental Protection Agency, D.C. Cir. Case No. 04-1385 (Dec. 4, 2006) at 53-54.

Comment: In order to provide additional compliance flexibility for sources, we also recommend EPA includes a health-based TSM compliance alternative along with the TSM emission limit option. Similar to the approach EPA took in the 2004 Boiler MACT rule, in the health-based TSM compliance alternative option, manganese emissions would not be included in the TSM calculation if facility emissions of manganese were below health-based thresholds established using either a lookup table or site specific modeling and risk analysis. Combustion of biomass fuels results in higher ratio of manganese to TSM than combustion of fossil fuels. We believe manganese is a threshold pollutant and it is appropriate to consider in a health-based regulatory approach.

Document Control Number: EPA-HQ-OAR-2002-0058-2865.1
Comment Excerpt Number: 7

Comment: The emissions of many units affected by the proposed rule pose absolutely no risk to human health or the environment because they are located in rural locations with few, if any, other affected facilities nearby. The "one size fits all" approach of the proposed rule, which treats urban and rural units equally, would force many harmless rural facilities to either inst•A 1 unnecessary and costly controls or shut down. Coastal encourages EPA to exercise its authority under Section 112(d)(4) to establish health-based emission limits, to be applied on a facility-by-facility basis, in order to avoid controls where it can be demonstrated that emissions are safe.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Document Control Number: EPA-HQ-OAR-2002-0058-2794.1
Comment Excerpt Number: 7

Comment: Health Based Emission Limits (HBEL) Should Be Provided in the Rule.

NEDA/CAP's members were disappointed to see that EPA proposed to brush aside the former ICI boiler and process heater MACT provisions for HBELs that would allow sources to demonstrate the absence of health effects for certain pollutants such as manganese and hydrogen chloride, known to have limited air pollution-related public health impacts. Both the policy rationales that are offered, and the assertions that environmental effects such as acid rain are related to these pollutants, are unreasonable and arbitrary. Notably, in NRDC v. EPA, the Court did not find a statutory issue with the HBEL provisions in the ICI boiler and process heater MACT rule, despite a vigorous opposition to those provisions by environmental groups and some states. NEDA/CAP urges the Agency to re-evaluate this option in the coming months, and certainly before the MACT compliance date for this NESHAP. We submit that Congress included section 112(d)(4) in the 1990 Clean Air Act Amendments for a purpose, and that EPA should use its authority under that provision to establish HBELs.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 8

Comment: Duke Energy Strongly Supports the Adoption of a Health Based Alternative Limit for Acid Gas HAPS (HCL, CL2, HF and HCN) Under § 112(d)(4)
The proposed rule requires facilities to take costly steps to control emissions even though those emissions may not result in exposures which could pose an excess individual lifetime cancer risk greater than one in one million or exceed thresholds determined to provide an ample margin of safety for protecting public health and the environment. The EPA recognizes in the preamble to the proposed rule that the Administrator has the authority under section 112(d) to establish emissions standards other than conventional MACT standards, in cases where a less stringent emission standard will ensure that a health threshold will not be exceeded with an ample margin of safety. See 75 Fed. Reg. 32030. Duke Energy believes that the EPA should use the authority granted under section 112(d) to establish health based alternative emission standards for the Acid Gas HAPs as compliance option in the final ICI Boiler MACT rule. Section 112(d)(4) is designed to prevent the promulgation of unduly stringent emission limits simply for the sake of regulation. Section 112(d)(4) allows EPA to set health-based limits for certain HAPs based on established health thresholds, rather than having to follow the technology forcing provisions of 112(d)(3).

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 8

Comment: The work that EPA performed in support of the HBELs included in the 2004 rule demonstrates that the proposed standards are far more stringent than needed to assure the protection of public health with an ample margin of safety. AMP hereby incorporates by reference (and asks that EPA formally incorporate into the administrative record) all of the support for the health-based compliance alternative included in the record for the 2004 Boiler MACT rule.

EPA asserts in the Proposed Rule that its decision not to propose HBELs "is not contrary to EPA's prior decisions where we found it appropriate to exercise the discretion to invoke the authority in section 112(d)(4) for HC1, since the circumstances in this case differ from previous considerations." 75 Fed. Reg. at 32032. It references "other source categories for which EPA has exercised its authority under section 112(d)(4)," and suggests that boilers and process heaters are more likely to be co-located with other HAP sources and are often located in heavily populated urban areas where many other HAP sources exist. Id. at 32031-32.

Those assertions are astonishing because they ignore the fact that EPA previously "found it appropriate to exercise the discretion to invoke the authority in section 112(d)(4)" as applied to this very category. EPA vigorously defended the HBELs included in the 2004 rule when it was challenged in the D.C. Circuit and dedicated 17 pages of its brief to explaining why its HBELs complied with the requirements of section 112(d)(4). In that brief, EPA acknowledged making the following determinations: (1) both HC1 and manganese have reference concentrations and have not been shown to be carcinogenic, (2) the HBELs provided an ample margin of safety, (3) "health-based standards would not reduce the HAP-related health benefits from the rule because only those facilities with emissions that did not pose a health risk would qualify for the alternative standards," (4) it is inappropriate to consider potential cumulative risks until the residual risk stage of the NESHAP process, and (5) "the potential collateral benefits of controls were not a proper reason to impose control costs under the HAPs program on facilities with HAP emissions that did not pose a public health risk." [Footnote: Final Brief For Respondent United States Environmental Protection Agency, D.C. Cir. Case No. 04-1385 (Dec. 4, 2006) at 59-65, 69.]EPA argued that each of these positions was reasonable, in accord with the law, and entitled to deference. Nothing in the Proposed Rule refutes these determinations.
SQl[IPI , SANDERS 84 I)EMPSEYL.L.P.
U.S. Environmental Protection ALIency Docket ID No. EPA-HQ-OAR-2002-0058 August 23, 2010
Page 13
EPA's decision to eliminate 11BELs from the Proposed Rule is completely at odds with EPA's prior determination that 11BELs are appropriate and justified for this source category. Although EPA has discretion in setting HBELs, "a reasoned c \plarmtion is needed for disregarding facts and circumstances that underlay or were engendered by [a] prior policy." FCC v. Fox Television Stations, Inc., 129 S. Ct. 1800, 1810 (2009). EPA has offered no such explanation. EPA's failure to acknowledge its prior determination and failure to explain why it has raised as questions issues that previously were resolved (such as how to consider co-located HAP sources and nearby HAP sources) render its decision not to propose HBELs arbitrary and capricious.

Commenter Name: Sean M. O'Keefe
Commenter Affiliation: Alexander and Baldwin, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 9

Comment: The Clean Air Act provides EPA with the flexibility to establish health-based emissions limitations (HBELs) for certain pollutants where a MACT emissions limit may be far more stringent than is necessary to protect human health and the environment. The vacated Boiler MACT standard included health-based emissions limitations for manganese and hydrogen chloride (HC1) that helped to reduce compliance costs compared to the technology-based standards that would have otherwise applied without compromising protection of human health and the environment. In the current proposal, however, EPA has elected not to establish any health-based emissions limitations, yet has provided no explanation as to why the justification for HBELs used in support of the earlier rule are no longer valid. A&B believes that the inclusion of HBELs provides an important means for EPA to increase the flexibility of the regulation and to reduce compliance costs without compromising environmental benefits. We therefore urge EPA to restore the HBEL provisions to the rule.

Comment: The objective of the NESHAP process is to protect public health. Why should any boiler operator be forced to spent resources if their particular boiler is not creating significant incremental risk to the public? EPA is inconsistent when protecting public health through existing programs. Presently several of the action levels EPA uses for drinking water pollutants are based on one excess lifetime cancer case per one hundred thousand exposed individuals. Why would EPA chose a standard for Boiler MACT that would result in reductions in risk of several orders of magnitude from current risks that are already well below this drinking water standard? If one of our boiler systems can be shown to offer excess lifetime cancer risks that are below the well accepted risk level of one lifetime excess lifetime cancer risk per one million exposed individuals and non-carcinogenic risks meaningfully below the accepted chronic exposure levels, why should our system be upgraded at all? Requiring organizations to incur expenses that don't provide meaningful improvement to public health is unacceptable public policy. We respectfully request that EPA reinstitute the health-based compliance alternative in the final version of this rule.

Document Control Number: EPA-HQ-OAR-2002-0058-2908.1
Comment Excerpt Number: 14

Comment: EPA has requested comments on whether it should impose a health-based standard under 112(d)(4) for HC1 and other acid gas emissions from industrial boilers. Section 112(d)(4) allows EPA to set health-based limits for certain HAPs based on established health thresholds, rather than having to follow the technology forcing provisions of 112(d)(3). EPA should allow facilities to demonstrate that emissions of certain pollutants do not pose a public health concern. If the emissions of a given HAP from all sources in a source category are at a level where public health is protected with an ample margin of safety, then there is no practical need for or benefit from further regulation. EPA should set health-based standards under § 112(d)(4) when facts support its use. This would target environmental investments where there is a real need based on a rigorous demonstration that pollutants do not pose an adverse risk.
When the first Industrial Boiler MACT was promulgated in 2004, it included health based emissions limitations for two HAPs — HC1 and manganese. While EPA acknowledges its authority under § 112(d)(4) to establish a health-based emissions limitation for threshold pollutants in lieu of a MACT emissions limitation, the Agency proposes not to establish any health based emissions limitations in this proposal. EPA should explain its decision to depart from the approach used in establishing health- based emissions limitations in the 2004 Industrial Boiler MACT.

Comment: The EPA should retain the health-based compliance option (HBCO) contained in the original Boiler MACT rule.

The basis of the original HBCO was that it was a waste of resources to require expensive controls in situations where the source presented no significant health and environmental risk. The EPA has not explained why it has abandoned this reasonable approach.

The statute, at paragraph 112(c)(9), plainly gives EPA the authority to not require controls on source categories that present no appreciable risk. This suggests that Congress intended that EPA need not require controls on sources that are very low risk.
Many of our members were able to meet the very conservative low risk provisions in the original Boiler MACT and this option should be retained in the major source rule.

Commenter Name: John C. deRuyter
Commenter Affiliation: DuPont
Document Control Number: EPA-HQ-OAR-2002-0058-2793.1
Comment Excerpt Number: 18

Comment: A risk-based compliance option under §112(d)(4) is particularly appropriate with respect to emissions of Hydrogen Chloride.

EPA has acknowledged in the prior vacated Subpart DDDDD rule that, in many cases, emissions of hydrogen chloride (HCl) from ICI boilers and process heaters will pose no risk to human health or the environment. Indeed, the available data suggested that a significant proportion of industrial boilers and process heaters do not emit HCl in an amount that would result in an exceedance of applicable health benchmarks. However, this proposed rule does not include a risk or health based approach. DuPont believes that inclusion of a risk based approach under §112(d)(4) is wholly appropriate and most appropriately implemented as a risk-based compliance option. Incorporating this option into the final rule would provide significant cost savings by foregoing the requirement for add-on controls on boilers and process heaters whose emissions do not result in HCl (and other inorganic HAP as appropriate) concentrations that exceed health benchmarks. Dispersion modeling conducted for the prior vacated rule indicated that many affected sources could utilize this means of compliance. This mechanism would ensure that ICI boilers and process heaters whose HCl emissions do exceed these benchmarks are controlled. EPA has ample legal authority under section §112(d)(4) of the CAA to implement this approach.

Such a risk-based compliance option could be implemented in two ways: (1) allow sources whose emissions result in exposures that are below the health threshold for HCl to forego the installation of technological controls, and (2) allow sources, as an alternative to full MACT controls, to control their HCl emissions down to a level that maintains exposures below the health benchmark. DuPont believes that the EPA should include in the final rule a compliance option for HCl that would allow facilities to demonstrate that the HCl concentrations measured at the nearest receptor to the facility cannot reasonably be expected to exceed the health benchmark represented by the RfC, as verified in EPA's IRIS database. Sources that qualify for this compliance option would ensure that the HCl exposures due to the facility's emissions do not increase beyond the RfC. DuPont believes that this approach holds great promise in focusing the rule on eliminating meaningful risks without giving rise to expenditures that provide insignificant meaningful environmental or public health benefit. Simplified, more flexible, and less onerous requirements that can still meet the risk criteria set out in the Clean Air Act would provide a much more cost effective rule while still providing adequate health and environmental protection.

Comment Excerpt Number: 106

Comment: EPA SHOULD CONSIDER HEALTH-BASED THRESHOLDS IN ESTABLISHING EMISSIONS LIMITS. Section 112(d)(4) gives EPA authority to consider a health-threshold established for a pollutant, with an ample margin of safety, when setting a standard for that pollutant. The purpose of this provision is to ensure that the technology driven standards established under section 112(d)(2) and (3) do not overregulate where no human health or environmental gain is to be had. Congress understood that for some pollutants "...a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment...To avoid expenditures by regulated entities which secure no public health or environmental benefit, the Administrator is given the discretionary authority to consider evidence for a health threshold higher than MACT..."[See Senate Report No.101-228, reprinted in U.S. Code and Congressional and Administrative News, 101st Congress, Second Session 1990 at p. 3556.]

Some of the HAPs regulated by this rule such as hydrogen chloride (HCl) and manganese (Mn) either have established thresholds or meet the requirements for classification as threshold pollutants and should therefore be considered for standard setting under section 112(d)(4).

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: These regulations should provide flexibility for compliance alternatives which can limit costs while maintainingyrotection for Public health and the environment. Overly broad application of "one size fits all" emissions limitations or monitoring protocols can at times lead to imposition of substantial costs and injury to competitive position. EPA should take advantage of the flexibility afforded by Section 112(d)(4) of the Clean Air Act and allow sources reasonable means for demonstrating that their respective emissions do not warrant further control because their respective impacts fall below acceptable health. thresholds. Sources should be afforded reasonable means for demonstrating significant differences in function, design or operating characteristics from hest performing sources such that they can properly avoid being subject to ill-suited requirements resulting from overly broad source categorization.

Response: See preamble for response to final decision on Health Based Compliance Alternative and discussion of MACT floor methodologies.

Comment Excerpt Number: 1

Comment: In the preamble, EPA stated it would need additional facility-specific emissions information to develop model plants and conduct the dispersion modeling necessary to establish health-based emission limits. These limits would need to be established to ensure that exposure is below the health threshold for this source category, and account for exposures from multiple adjacent sources as well as short-term emission increases. Currently, EPA has very limited information on facility-specific emissions, plant configurations, and overall fence-line characteristics for this source category. Given these data are required to establish health based standards, EPA is requesting such information to evaluate the feasibility of health-based emission limits.

NC DAQ thinks EPA should exercise its Section 112(d)(4) authority to establish health based emission limits for hydrogen chloride (HC1) and other acid gases. This would enable EPA to match proposed HC1 emission limits with the level determined to be health protective. To help accomplish this objective, EPA could use the NC air toxics program as a model methodology and source of dispersion modeling data.

Comment Excerpt Number: 1

Comment: EPA Should Have Adopted A Health-Based Compliance Alternative (HBCA)Which Provides Alternative Emission Limits for Threshold Chemicals

EPA has proposed not to exercise its discretion to use section 112(d)(4) to establish a health-based emission standard for HCL and manganese, despite acknowledging that it has such discretion under the Clean Air Act. For its part, the Boiler MACT Panel Report recommends that "EPA adopt the HBCA as a regulatory flexibility option for the Boiler MACT rulemaking. The panel recognizes, however, that EPA has concerns about its legal authority to provide and HBCA under the Clean Air Act, and EPA may ultimately determine that this flexibility is inconsistent with the Clean Air Act." [Footnote: SBAR Panel Report at 23.] In fact, EPA has not determined that the 112(d)(4) discretion is inconsistent with the Clean Air Act, nor has it determined that a health-based emission standard cannot be developed for HCl. Rather, EPA simply takes that position that it does have sufficient information to establish an HCl standard under section 112(d)(4), and EPA failed to adequately explain why it is failing to reaffirm the HBCA approach it adopted in the 2004 final boiler rule. Further, the Department of Justice, stated in its brief defending the previous use of 112(d)(4) in the boiler rule, that claims that the statute precludes the adoption of alternative standards was "meritless." [Footnote: "Environmental Petitioner's claim that the statute precludes EPA from establishing alternative standards for threshold pollutants (which petitioners mischaracterize as an exemption) is meritless. Final Brief For Respondent United States EPA, D.C. Cir Case No. 04-1385 (December 4, 2006) at 53-54.] Significantly, small entity representatives commented during the Panel that "adopting an HBCA . . . would be the most important step EPA could take to mitigate the serious financial harm the Boiler MACT would otherwise inflict on small entities . . . [t]herefore, HBCA should be a critical component of any future rule to lesson impact on small entities." [Footnote: SBAR Panel Report at 23.] Because EPA has not determined that an HCl HBCA is inconsistent with the Clean Air Act, EPA should have followed the unanimous Panel recommendation and adopted the HBCA for HCl and manganese as a regulatory flexibility option. Such an alternative alone is widely expected to save substantial capital and annual costs, and prevent a significant number of plant shutdowns and job losses, with no detriment to environmental protection. [Footnote: In the 2004 final Boiler rule, vacated for other reasons, it was estimated that the HBCA approach saved over $2 billion. See American Forest and Paper Association comments filed August 23, 2010 in this docket. The AF&PA SER comments estimated capital savings in excess of $100 million just for the small facilities in the pulp & paper sector. SBAR Panel Report at 41. It was disappointing that EPA's discussion of the alternative approach provided no assessment of what costs might be saved by this alternative approach, and that might explain why this alternative was not more seriously considered.]

Comment: EPA should establish health based emissions limitations for acid gases and manganese: In the Industrial Boiler MACT promulgated in 2004, EPA proposed and supported health based emissions limitations (HBEL) for hydrogen chloride (HCl) and manganese. However, in the proposed Industrial Boiler MACT, EPA has arbitrarily chosen not to establish any HBELs nor do they provide a justification for facilities needing to spend millions of dollars in compliance costs on pollutants for which EPA cannot demonstrate an adverse health effect EPA has previously acknowledged that a threshold has been established for both HC1 and manganese below which no adverse effects are observed and concluded that health and safety were protected with an ample margin of safety when the concentrations of these pollutants at the point of exposure were below the threshold for health effects. Furthermore, HBELs are fully justified on scientific and technical grounds. Safe concentrations of HC1 and Mn can be assured, as was proposed in 2004, when facilities meet designated stack heights and fenceline distances sufficient to keep HC1 and Mn below risk thresholds at the point of exposure.

EPA has the legal discretion, under CAA 112(d)(4), and technical justification to set health-based emissions limitations for pollutants "for which a health threshold has been established" thereby substantially reducing the burden of the standard while still providing ample protection to health and the environment. EPA should set HBELs for HAP acid gases and, like in the2004 rule, a health based emissions limit for manganese, which should be implemented in conjunction with a Total Select Metal ("TSM") standard (where the TSM standard would be an alternative to the PM surrogate, and where a "TSM less manganese" option would be provided when a source elects to comply with the health based compliance alternative for manganese).

Comment: The Boiler MACT proposal asks for comments on an approach that would allow facilities to demonstrate that emissions of certain pollutants do not pose a public health threat (p. 32031- 32032). RED believes EPA has the authority under section 112(d)(4) to provide for flexibility where releases don't threaten public health. In a biomass-power facility, for instance, this approach would have EPA allow threshold substances, such as hydrogen chloride and manganese, which in small quantities do not risk a community's health.

RED also suggests EPA adopt a more flexible approach that addresses the diversity of boilers, operations, sectors, and fuels. Such an approach would preserve environmental quality and prevent severe job and productivity losses.

Comment: EPA proposes cumbersome and costly regulations for these clean biomass burning forest-product facilities that are more appropriate for boilers at industrial and chemical manufacturers or refiners. Similarly, EPA proposes regulations appropriate for incinerators burning scrap tires, plastics and solvents to apply also to forest-product producers using woody biomass byproduct to fuel their operations. In most all cases, EPA proposed emissions levels far exceed what is necessary to protect human health from biomass energy operations. Of course, we cannot compromise our goal of protecting human health. Therefore, the more common-sense solution is to use a health-based standard and allow facilities to show they are not endangering human health. That, after all, is the true goal of the Clean Air Act and is specifically authorized by that Act in section 112(d)(4).

Comment: I strongly support the EPA’s decision to reduce toxic pollution from such boilers, and especially applaud the EPA’s proposed regulation of hydrochloric acid and other dangerous acid gases produced by commercial and industrial boilers. Such acids pose substantial risks to industrial workers, as well as surrounding communities, and must be limited by the strict conventional Maximum Achievable Control Technology standards. I oppose any effort to establish a lesser "health-based" standard for acid gases; no such health-based standard exists.

Comment: CBEA recommends exercising your authority in Section 112(d)(4) which already authorizes EPA to set health-based emissions limitations when establishing standards for HAPs under § 112(d). Section 112(d)(4) is a powerful tool that enables EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than needed to get the job done.

The default technology-based method of setting MACT standards is a cookie cutter approach that can and does result in HAP emissions limitations that go well beyond what is needed to protect the public from HAP emissions. The clear purpose of § 112(d)(4) is to prevent this from happening. The legislative history of § 112(d)(4) is abundantly clear on this point. In formulating § 112(d)(4), Congress recognized that, "For some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment." 1 As a result, § 112(d)(4) was provided as an alternative standard setting mechanism for HAPs "where health thresholds are well-established ... and the pollutant presents no risk of other adverse health effects, including cancer....”

Comment: The proposal asks for comment on an approach that would allow facilities to demonstrate that emissions of certain pollutants do not pose a public health threat. We believe EPA has such flexibility under section 112(d)(4). We believe that provision reflects Congress' intent to provide for flexibility where there is not a public health threat. In such cases, it makes sense to allow that approach in the final rule for threshold substances such as hydrogen chloride and manganese.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: Health-Based Emission Limits for Small Utilities: HBPW also supports health-based emissions limits ("HBELS") as EPA proposed and supported for the Boiler MACT source category under the 2004 Boiler MACT rule. EPA has clear authority to adopt HBELs under section CAA 112(d)(4) for pollutants "for which a health threshold has been established." As EPA previously acknowledged, a threshold below which no adverse effects are observed has been established for both HCI and manganese. In 2004, EPA concluded that health and safety were protected with an ample margin of safety when the concentrations of HCI or manganese at the point of exposure were below the threshold for health effects. These safe concentrations of HCI and Mn can be assured, as was proposed in 2004, when facilities meet designated stack heights and fenceline distances sufficient to keep HCI and Mn below risk thrsholds at the point of exposure. EPA has arbitrarily eliminated HBELs from the proposed rule without providing an adequate explanation for the change.
We believe that EPA has a duty under SBREFA to consider compliance costs and regulatory alternatives that could ease the burden on small entities such as the HBPW. The EPA convened the Small Business Advocacy Panel, which identified health-based compliance alternatives as "the most important step EPA could take to mitigate the serious financial harm the Boiler MACT would otherwise inflict on small entities using solid fuels nationwide...." When EPA adopted a health-based alternative for HCI in 2004, it estimated that affected sources would save $2 billion in compliance costs at no expense to human health or the environment.

We request that the EPA reconsider keeping the HBELs for HCL and manganese in the proposed Boiler MACT rule, or provide a valid explanation for why an HBEL is no longer available to small entities and what now justifies wasting billions of dollars in compliance costs on pollutants for which EPA cannot demonstrate an adverse health effect.

Comment Excerpt Number: 6

Comment: The 2004 Industrial Boiler MACT, promulgated in 2004, included a health based emission limit for both hydrogen chloride and manganese emissions. The health based compliance alternative (HBCA) was set at levels determined necessary to fully protect human health for units that meet the criteria. The Shiras Steam Plant, due to the large stack heights and distance to fence lines, was able to comply with the 2004 HBCA requirements. To set standards that require emission reductions far below the levels needed to assure the public and environment are fully protected puts an unnecessary financial burden on small communities. Again, it bears repeating that the applicable boiler at the Shiras Steam Plant demonstrated compliance with the 2004 health based compliance alternative, which was set at a level that fully protected human health with an ample margin of safety. Areas with numerous sources most likely have a larger base to distribute the cost of necessary controls. However, as is the case in Marquette, installing a scrubber on a unit that already demonstrates that it poses no risk to human health and the environment will distribute this unnecessary cost over a population of approximately 21,000 people with an average income of $35,000.

Comment Excerpt Number: 7

Comment: The establishment of a Health Based Compliance Alternative (HBCA) under CAA Section 112(d)(4) remains a legally defensible and logically viable approach for the Boiler MACT rule. During the litigation over the 2004 Boiler MACT rule, actively defended its adoption of the HBCA. Although the Court of Appeals vacated the Boiler MACT rule for other reasons, they did not rule on the merits of the HBCA. Thus, we urge EPA to proceed with adoption of the HBCA in the current Boiler MACT rule.
By demonstrating negligible offsite risk via an HBCA approach, a participating source benefits the surrounding community by addressing in advance a primary goal of the MACT regulation, which is to reduce offsite risk to safe levels. This approach is very similar to the Residual Risk Review required under CAA Section 112(f)(2) that would otherwise occur at a much later date. The source benefits by implementing a common-sense approach to HAP control that avoids installation of control devices that provide little or no HAP risk reduction at considerable cost. The only remaining portion of residual risk to be addressed after the HBCA is multiple source impact, which is specifically designated in the CAA for completion after implementation of the MACT regulation.

Comment: Congress established the basis for the HBCA
Within Section 112(d) of the 1990 Clean Air Act (CAA), Amendments, which directs EPA to develop Maximum Achievable Control Technology (MACT) standards, there is a subsection, 112(d)(4), that allows EPA to consider whether emissions from a regulated HAP could affect human health in establishing MACT standards for a particular category:
112(d)(4): Health threshold- With respect to pollutants for which a health threshold has been established, the Administrator may consider such threshold level, with an ample margin of safety, when establishing emission standards under this subsection.
As discussed more fully by AF&PA, this section of the CAA provides EPA the authority to establish health based standards for threshold pollutants that are protective of public health with an ample margin of safety.

Comment: EPA has utilized this mechanism in the vacated Boiler MACT rule and several other MACT standards.
In the original 2004 Boiler MACT rule, EPA determined that two HAPs, hydrogen chloride (HCl) and manganese (Mn), are threshold pollutants that do not pose a significant health risk at a potentially large proportion of regulated sources. If affected sources were able to demonstrate that health benchmarks could be met for these HAPs, emission controls for these materials were not necessary.
Similar considerations for addressing HCl as a threshold pollutant have been included in several other National Emission Standards for Hazardous Air Pollutants standards:
1. Hazardous Waste Combustors (Phase I Final Replacement Standards and Phase II)
2. Chemical Recovery Combustion Sources At Kraft, Soda, Sulfite, And Stand-Alone Semichemical Pulp Mills;
3. Portland Cement Manufacturing Industry; and
4. Chlorine and Hydrochloric Acid Emissions From Chlorine Production.

Comment: Section § 112(d)(4)'s inclusion in the 1990 CAA Amendments indicates a Congressional intent to retain the health endpoint of the original § 112 -- protection of public health with an ample margin of safety. If the emissions of a given HAP from all sources in a source category are at a level where public health is protected with an ample margin of safety, then there is no practical need for or benefit from further regulation. NRECA encourages EPA to set health-base standards under § 112(d)(4) when facts support its use.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 10

Comment: EPA has requested comments on whether it should impose a health-based standard under § 112(d)(4) for HCl and other acid gas emissions from IBs. See 75 Fed. Reg. at 32,030. Section 112(d)(4) is designed to prevent the promulgation of unduly stringent emission limits simply for the sake of regulation. Section 112(d)(4) allows EPA to set health-based limits for certain HAPs based on established health thresholds, rather than having to follow the technology forcing provisions of § 112(d)(3). As a practical matter, § 112(d)(4) applies to non-carcinogenic HAPs [Almost without exception, EPA assumes a linear, no-threshold dose-effect relationship for HAPs that are classified as carcinogens.] for which EPA has established a health threshold such as a reference concentration ("RfC") or a reference dose ("RfD"). EPA defines a reference concentration in its Information Risk Information System ("IRIS") database as "[a]n estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime."[The definition for a reference dose is essentially the same except it focuses on exposures by pathways other than inhalation.] Thus, human exposures to a HAP at levels below its RfC are considered "safe" particularly given the uncertainty factors that EPA includes as part of its derivation of a RfC.

Congress' inclusion of § 112(d)(4) in the 1990 CAA Amendments indicates an intent to retain the health endpoint of the original § 112 -- protection of public health with an ample margin of safety.[The ample margin of safety concept also underlies the current residual risk provisions of CAA § 112(f).] If the emissions of a given HAP from all sources in a source category are at a level where public health is protected with an ample margin of safety, then there is no practical need for or benefit from further regulation. EPA should set health-based standards under § 112(d)(4) when facts support its use.

Comment: EPA should reinstate the risk assessment option for HCL and manganese
In the original boiler MACT rule, EPA offered a risk assessment option for sources that could demonstrate acceptable ambient impacts of HCL or manganese in lieu of complying with an emission limit. We urge EPA to reinstate this option for the proposed Boiler MACT Rule. Biomass boilers are typically located in rural areas, so concerns with multiple sources of exposure in heavy industrial areas discussed on pages 32031 to 32032 is not a concern for our sources.

Comment: EPA should consider health-based impact as part of the evaluation process. Facilities in rural areas should not be required to add pollution controls. DGC is an example of this because there is a sparse residential population of only 51 residents within a 4.5 mile radius of our facility. Also, pollution controls may be unnecessary considering physical parameters at DGC which would include the dispersion environment and the 400 foot stack height. DGC is requesting that EPA use its discretion to set a health-based alternative to numeric limits. If a source can demonstrate that emissions are below the agencies risk exposure limit for public health, that option would make sense in lieu of extremely low emission limits. DGC encourages EPA to include a health threshold option in the final rule.

Comment Excerpt Number: 11

Comment: The EPA should retain the health-based compliance option (HBCO) contained in the original Boiler MACT rule.

The basis of the original HBCO was that it was a waste of resources to require expensive controls in situations where the source presented no significant health and environmental risk. The EPA has not explained why it has abandoned this reasonable approach.

The statute, at Section 112(c)(9) and 112(d)(4) , plainly gives EPA the authority to not require controls on categories or sources that present no appreciable risk. This suggests that Congress intended that EPA need not require controls on sources that are low risk.

Comment Excerpt Number: 12

Comment: Scientific information supports a determination that HCl, HF, HCN, and Mn are threshold pollutants and, thus, are eligible to be regulated under § 112(d)(4). In addition, the Agency has the technical tools and significant factual support for establishing health based emissions limitations for these HAPs that would provide the requisite ample margin of safety to health and the environment. EPA should set health based emission limitations for HAP acid gases and, like in the 2004 rule, a health based emissions limit for manganese, which should be implemented in conjunction with a Total Select Metal (TSM) standard (where the TSM standard would be an alternative to the PM surrogate, and where a “TSM less Mn” option would be provided when a source elects to comply with the health based compliance alternative for Mn).

Commenter Name: Allyn Ford
Commenter Affiliation: Roseburg Forest Products
Document Control Number: EPA-HQ-OAR-2002-0058-3163
Comment Excerpt Number: 12

Comment: EPA has other, less economically devastating means available to minimize HAP emissions and to protect public health:

Section 112(d) of the Clean Air Act allows EPA to integrate into its rules the ability for facilities to demonstrate that risks from certain pollutants are safe. This certainly should be allowed in the case of biomass-fired combustion units. As discussed above, costs associated with controlling biomass units are particularly significant since they are burning relatively clean fuel. Allowing these facilities to demonstrate that the fuels they burn and the resulting emissions do not pose an unsafe risk will inject some reason into the standards. It will most certainly serve to save jobs.

A limited risk-based approach could be integrated into the rule by creating a total select metals standard as an alternative approach to the particulate matter standard. Once in place, provide for an option allowing facilities to demonstrate that the manganese emissions do not pose an unsafe risk. The same could be true of HCI emissions.

A risk-based approach truly gets at the issue of protecting human health, whereas surrogate pollutants and best performing emission rates may be overprotective at some facilities while being less than protective at others. A risk based approach is also based on site-specific data that affects dispersion and hence, risk. For instance, two facilities with similar emission rates, but different stack heights, diameters, flowrates, topography, and meteorology may have wildly different impacts to human health. For this reason, Roseburg Forest Products believes that the proposed MACT rules likely do not have an adequate level of control at some facilities while severely and unnecessarily penalizing other facilities that do not have an adverse impact. The proposed blanket approach to HAP regulation will have significant impacts on facilities and may even cause some facilities to close that do not have a significant impact on human health and the environment.

Comment: NAFO further believes that EPA should exercise its authority under CAA §112(d)(4) to establish a health-based emissions limitation for HCl and manganese. This approach would ensure that public health is protected while eliminating the extreme cost to industry that could result from the proposed MACT emissions limitations.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: When the first Industrial Boiler MACT was promulgated in 2004, it included health based emissions limitations for two HAPs – HCl and manganese. These health-based emissions limitations were rigorous standards that demanded accountability. They were a winner for the Agency and the public because public health would have been protected with an ample margin of safety. At the same time these standards were a winner for affected sources because the standards would not have blindly required emissions to be reduced far below the levels needed to assure that the public was protected. It was estimated at the time that these health based standards would have saved over $2 billion in compliance costs, as compared to the technology-based standards that otherwise would ave applied.

In its proposed Major Boiler MACT rule, EPA acknowledges its authority under Section 112(d)(4) to establish a health-based emissions limitation for threshold pollutants in lieu of a MACT emissions limitation. However, the Agency proposes not to establish any health based emissions limitations "[g]iven the limitations of the currently available information (i.e., the HAP mix where boilers are located, and the cumulative health impacts from co-located sources), the environmental effects of HCl, and the significant co-benefits of setting a conventional MACT standard for HCl." (75 FR 32032). Nevertheless, EPA asks for comment on a wide range of issues related to the justification for setting health based emissions limitations and the method by which they should be set.

Comment: IP supports a health based control alternative because it is allowed by statute and should lead to pragmatic decisions regarding HCl and other pollutants.

EPA has the ability under CAA section 112(d)(4) to set health-based emission limits. IP encourages EPA to exercise its discretion to do so. The current limits are more stringent than needed to assure appropriate protection of health and the environment from industrial boiler HAP emissions. Using its discretionary authority under the CAA would allow EPA to craft appropriate rules that should yield more pragmatic regulatory results.

Every opportunity to minimize excessive or unnecessary control costs beyond what is needed from a health and environmental protection perspective should be employed to minimize the cost of the Boiler MACT regulation, which under any circumstances appears will be exceedingly high for the environmental and public benefit it provides.

Comment: In many cases, remote/island facilities are located in areas which have few or no other major or even significant area sources. For tropical islands, the unique meteorological conditions of the area result in resident population being exposed infrequently to emissions from the facility. For example, this is the wind rose for St. Croix:

The result is that emissions from this refinery, which is located on the south shore of St. Croix, rarely blow inland. For this reason, we believe that EPA can also use its authority under Section 112(d)(4) to set emissions standards for island/remote facilities, particularly given the compelling differences between these facilities and mainland facilities.

A good example for health based regulation for island facilities may be mercury, where data available clearly indicates that fuel oil combustion presents no real relative risk. Mercury in coal is two orders of magnitude higher than mercury in fuel oil, based on HOVENSA's review of information in the docket. EPA estimated mercury present in residual fuel oil as being no more than 400 kg annually.37 This quote illustrates the exceptionally limited risk posed by residual fuel oil combustion:
"Significance. The mass of coal burned in the U.S. annually (1012 kg/y) is approximately the same as the mass of oil refined in the U.S. annually (13). The concentration of mercury in all U.S coal (coal rank volume corrected) is approximately 100 g/kg (1, 2). From the measured mean concentration for total mercury in oil and total annual volume (2004), oil that passes through U.S. refineries contains approximately 3 metric tons of mercury. The maximum amount of mercury released to the ecosphere from oil processed in the U.S. is, therefore, approximately less than 5% of that which may be derived from burning coal in any given year."38
There is little environmental or health based reason to force HOVENSA and other remote facilities to retrofit with expensive controls to address mercury from fuel oil combustion.

Comment: Section 112(d)(4) is a tool that enables EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than needed to get the job done. As EPA explains in the proposed rule, 112(d) generally requires MACT emissions limitations to be set at a level that reflects the performance of the better performing sources in the given source category or subcategory. Section 112(d)(4) provides an alternative to this basic approach for pollutants for which a health threshold has been established. For such pollutants, 112(d)(4) authorizes EPA to "consider such threshold levels, with an ample margin of safety, when establishing emission standards" under 112(d).

The default technology-based method of setting MACT standards is a cookie cutter approach that can and does result in HAP emissions limitations that go well beyond what is needed to protect the public from HAP emissions. The clear purpose of 112(d)(4) is to prevent this from happening. The legislative history of 112(d)(4) is abundantly clear on this point. In formulating 112(d)(4), Congress recognized that, "For some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment." [Footnote: S. Rep. No. 101-228 (1990) at 171.] As a result, 112(d)(4) was provided as an alternative standard setting mechanism for HAPs "where health thresholds are well-established ... and the pollutant presents no risk of other adverse health effects, including cancer...." [Footnote: S. Rep. No. 101-228 (1990) at 171.]

Comment Excerpt Number: 71

Comment: When the first Industrial Boiler MACT was promulgated in 2004, it included health based emissions limitations for HCl and manganese. Under both of these standards, a site-specific risk assessment had to be conducted to prove that emissions from the site were low enough that human health would be protected, with an ample margin of safety. Actual emissions testing of all affected emissions points was required to verify the emissions rates used in the risk assessment. All relevant site parameters were required to be recorded in the site's Title V operating permit to provide assurance over time that public health would be adequately protected. [Footnote: See, generally, 69 Fed. Reg. 55218, 55227-55228 (Sept. 13, 2004).]

In short, these health-based emissions limitations were rigorous standards that demanded accountability. At the same time these standards were a winner for affected sources because the standards would not have blindly required emissions to be reduced far below the levels needed to assure that the public was protected. It was estimated at the time that these health based standards would have saved over $2 billion in compliance costs, as compared to the technology-based standards that otherwise would have applied. The first Industrial Boiler MACT was overturned by the D.C. Circuit, but on grounds unrelated to the health based emissions limitations. Notably, in defending the health based emissions limitations, the Department of Justice concluded that, "Environmental Petitioners' claim that the statute precludes EPA from establishing alternative standards for threshold pollutants (which petitioners mischaracterize as an exemption) is meritless." [Footnote: Final Brief For Respondent United States Environmental Protection Agency, D.C. Cir. Case No. 04- 1385 (Dec. 4, 2006) at 53-54.]

Giving full consideration to the use of health-based standards is particularly important in the wake of the series of decisions from the D.C. Circuit that have progressively limited EPA's discretion to make common-sense decisions when setting MACT standards under 112. EPA's authority to set health based standards under 112(d)(4) is unassailable. For appropriate HAPs and where the relevant facts substantiate its use, EPA can set health-based standards with full confidence that they will survive judicial review.

Comment: We believe, perhaps because of the compartmentalization within EPA,[The proposed IB MACT rule was prepared by the Sector Polices and Programs Division within EPA's Office of Air Quality Planning and Standards (OAQPS). The Health and Environmental Impacts Division, also within
OAQPS, is responsible for assessing risks of air pollution and setting national ambient air quality standards.] the Agency has overlooked a fundamental issue with respect to its treatment of HC1 and HF. To advance this argument, we quote the following sections from the Clean Air Act. For the purpose of establishing national primary and secondary ambient air quality standards, the Administrator shall within 30 days after the date of enactment of the Clean Air Act Amendments of 1970 publish, and from time to time thereafter revise, a list which includes each air pollutant —
A. emissions of which, in his judgment, cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare;
B. the presence of which in the ambient air results from numerous and diverse mobile or stationary sources.[42 U.S.C. §7408(a)(1).]

Clearly HC1 and HF would qualify as potential criteria pollutants (e.g., emitted by numerous and diverse sources). Notwithstanding section 112(d)(4), if the Administrator has any reason to believe the levels of either HC1 or HF in the ambient air [This includes emissions not only from industrial boilers but also emissions from all mobile and stationary sources.] reasonably endanger public health or welfare, she is derelict in her duties for failing to set a national ambient air quality standard (NAAQS). If we conclude the Administrator is not derelict in her duties, then the only logical conclusion to reach is that neither HCl nor HF concentration in the ambient air endanger public health or welfare. Thus, all of the Agency's tortured discussion about the difficulty of using the authority provided for in section 112(d)(4) is really unnecessary because neither HC1 nor HF pose any health risks.

Comment Excerpt Number: 107

Comment: Basis for a section 112(d)(4) Standard. section 112(d)(4) enables EPA to establish a standard that is not purely technology driven and to consider the health-threshold of a pollutant is setting that standard. This provision expresses Congress" concern that sources not be over-regulated by technology when technology-driven emission reductions go beyond was is necessary to protect human health with an ample margin of safety.

In the 2004 Boiler rule, EPA determined that two HAPs commonly emitted from solid fuel industrial boilers, hydrogen chloride (HCl) and manganese (Mn), are threshold pollutants. Similar considerations for addressing HCl as a threshold pollutant have been included in 1) NESHAP; Final Standards for Hazardous Air Pollutants for Hazardous Waste Combustors (Phase I Final Replacement Standards and Phase II); Final Rule; 2) NESHAP; Proposed Standards For Hazardous Air Pollutants From Chemical Recovery Combustion Sources At Kraft, Soda, Sulfite, And Stand-Alone Semichemical Pulp Mills; 3) NESHAP:Portland Cement Manufacturing Industry; and 4) NESHAP: Chlorine and Hydrochloric Acid Emissions From Chlorine Production. In the absence of specific scientific evidence to the contrary, it has historically been EPA's policy to classify non-carcinogenic effects as threshold effects, as demonstrated in the above rulemakings.

In the 2004 Boiler rule EPA concluded the following:

Hydrogen chloride is the chief acid gas HAP from solid fuel combustion and emissions are related to chloride and chlorine content in fuel. Hydrogen chloride and chlorine are threshold HAPs with associated similar effects and established Reference Concentrations (RfC), such that the combined inhalation risks of these HAPs can be considered collectively.

Manganese is a threshold HAP metal, which is a chief risk driver for wood-fired boilers. The rule included emission standards for Total Selected Metals (TSM), of which manganese was a component, but the rule exempted manganese from the TSM calculation.

Section 112(d)(4) requires that all boilers (i.e, from the same MACT source category) at a single facility not significantly contribute to risk. It does not require risk evaluation of other HAPs with different types of health effects or contribution from other sources or background concentrations, as presently suggested in the proposed rule. EPA stated the basis for this determination in response to comments that cumulative risks should be evaluated under the health based compliance alternative.

EPA responded that section 112(d)(4) does not indicate that a risk assessment should be undertaken, but simply that the threshold level of a particular HAP should be considered and that it is appropriate to consider cumulative risk under section 112(f), which requires the evaluation of residual risk after the implementation of MACT standards.

The preamble to this 2010 boiler proposed rule deviates from EPA's direct interpretation of section 112(d)(4) in the 2004 Boiler rule by expanding the consideration of a pollutant's threshold level to other unrelated issues such as the co-benefit of technology controls reducing emissions of criteria pollutants. Although such objectives may appear to be meritorious from an overall environmental protection perspective, there is no indication from the language of

112(d)(4) that other factors besides human health effects of specific threshold HAPs are intended to be considered.

Comment Excerpt Number: 8

Comment: EPA has the authority to set health-based emissions standards and needs to include a Health-Based Compliance Alternative (HBCA) for meeting the HCl (acid gases) emissions limits. Section 112(d)(4) authorizes EPA to set health-based emissions limitations when establishing standards for HAPs under § 112(d). Section 112(d)(4) is a powerful tool that enables EPA to match the stringency of a HAP emissions limitation to the level determined necessary to fully protect human health. As a result, the standard is no more stringent and no less stringent than needed to get the job done. The legislative history of § 112(d)(4) is abundantly clear on this point. In formulating § 112(d)(4), Congress recognized that, “For some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment.” 2 As a result, § 112(d)(4) was provided as an alternative standard setting mechanism for HAPs “where health thresholds are well-established ... and the pollutant presents no risk of other adverse health effects, including cancer....”[footnote: S. Rep. No. 101-228 (1990) at 171.] PPG urges EPA to establish health-based emissions limits for sources to demonstrate adequate protection of human health as allowed under §112(d)(4) of the Clean Air Act, by considering emissions of HCl, Cl2, HF and HCN from the affected source in comparison against the appropriate RfC. PPG contends that evaluating a source’s HCl emissions against the RfC will provide ample protection to public health with a margin of safety.

Document Control Number: EPA-HQ-OAR-2002-0058-3220
Comment Excerpt Number: 2

Comment: Alternative Health-Based Limits Under Section 112(d)(4).
In the proposed rule, EPA recognizes its authority under section 112(d)(4) of the Clean Air Act to set health-based emission limits as an alternative to the MACT standards if it determines that such limits adequately protect public health, including a margin of safety. This mechanism is intended to be used when MACT standards may be more stringent than is necessary to protect public health and the environment. The result would be a rule that is protective, but eliminates costs that are unnecessary.

The EPA asked for comment on the use of section 112(d)(4), but chose not to propose the use of the health-based mechanism as an alternative to the MACT standard. We believe that EPA should exercise its discretion to use this provision to set limits for acid gases and manganese. As documented in the AF&PA comments, significant factual support exists for establishing health-based limits for acid gases (hydrogen chloride) and manganese.

Comment Excerpt Number: 2

Comment: KapStone also questions the stringent limits when the results from EPA's air toxics at school monitoring program that was conducted at Chicora Elementary School located in North Charleston, South Carolina showed results from HAP pollutants well below the screening values established by EPA. Our cogeneration boiler in North Charleston is the largest industrial source located in close proximity to Chicora Elementary School, however our "best performing" boiler may not meet the proposed Industrial Boiler MACT standards. The recent monitoring at the school shows that stringent reductions imposed by the proposed Boiler MACT standard are not necessary to meet health-based compliance concentrations.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 38

Comment: Many of the HAPs for which HCl and PM are surrogates are potential or demonstrated carcinogens. Moreover, because no meaningful studies have been conducted, EPA has identified both HCl and manganese as unclassifiable for carcinogenicity. For this reason it cannot be asserted that a "well-established" threshold exists and that there is no risk of cancer. EPA's Integrated Risk Information System (IRIS) reports that no studies have identified a No Observable Effects Level (NOEL) for neurological effects for manganese. See http://www.epa.gov/iris/subst/0373.htm;http://www.epa.gov/ncea/iris/subst/0396.htm.] Further, the CAA requires that a section 112(d)(4) standard include "an ample margin of safety." EPA's IRIS report concludes that the scientific confidence in the Oral Reference Concentration for HCl employed by EPA in the ICI Boiler “risk-based exemption” is “low.”[The IRIS report concludes “[t]he chronic study used only one dose and limited toxicological measurements. The supporting data consist of two subchronic bioassays; the database does not provide any additional chronic or reproductive studies. Therefore, low confidence was recommended for the study, database, and the RfC”.] For this reason, it cannot be said that the “well established” threshold that provides an “ample margin of safety” has been established for HCl. Broader approaches for alternate emission standards were specifically rejected by Congress in the development of section 112.[Congress specifically rejected an amendment that would have provided that individual sources “could comply with alternative emission limitations in lieu of standards under this section, if the owner or operator presents evidence sufficient to demonstrate that emissions from the source in compliance with such limitations present a negligible risk to public health under criteria issued by the Administrator.” 2 Legislative History, at 3939. The Act itself provides a specific alternative emission standard for coke oven batteries. Thus, a risk-based exemption for specific sources is contrary to the statutory structure and would not be approved under a deminimis test, even if the emissions impacts were trivial. EPA’s history over the past 40 years in attempting to develop a risk-based approach to regulations of toxic air emissions, and in particular the development of residual risk programs under section 112, demonstrate that these issues are far too complex and significant to be delegated to individual sources as EPA intended.]

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council
Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 59

Comment: That is also true, as a technical matter, because health effects are based both on exposure and toxicity, and these factors vary significantly between HAPs. The California standards for the acid gases EPA seeks information on -- chlorine, HF and HCN – show that these pollutants are more toxic on a weight/volume basis than HCl (considering the respiration/inhalation pathway of exposure). And chlorine, HCN and HF are approximately 10 times more toxic than HCl for short-term exposures. Therefore, unless chlorine, HF, and HCN are always present at concentrations that are ten-fold lower than HCl, even for short durations (and EPA does not have such information), only separate health-based thresholds could ever be technically justified.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council

Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 60

Comment: The requirement that §112(d)(4) standards must incorporate "an ample margin of safety" prohibits EPA from acting under this section where it lacks evidence on certain dimensions of health risk.

The "ample margin of safety" language in section 112(d)(4) means at the very least that any standard that is set under this authority must be sufficient to protect against significant unforeseen consequences, particularly where the Agency is aware that those consequences may occur, but simply does not have enough evidence about them. See, e.g. EDF v. EPA, 598 F.2d 62, 81 (D.C.Cir. 1978)(holding that the phrase 'ample margin of safety' in the Clean Water Act's toxic provisions required EPA to protect against as yet unidentified risks to human health, including those "which research has not yet identified."). The fact that EPA has in previous rulemakings, asserted that it was appropriate to exercise § 112(d)(4) discretion in the absence of evidence of carcinogenic risk, and on the limited understanding of the health risks it did have, [Footnote: See 75 Fed. Reg. 32,020 (citing statements made in EPA's 1998 Pulp and Paper MACT, 63 Fed. Reg. at 18,765 (April 15, 1998) and Lime Manufacturing MACT, 67 Fed. Reg. at 78,054 (Dec. 20, 2002)).] does not make that interpretation correct. The absence of evidence of risk is not sufficient to demonstrate that an "ample margin of safety" exists. In fact, EPA's prior view turns the statutory requirement, as interpreted by the D.C. Circuit, on its head. Because the 'ample margin of safety' requirement is meant to protect against risks that have not yet been identified in research , a section 112(d)(4) standard simply cannot be justified on grounds that EPA does not have sufficient evidence about the health risks posed by a HAP.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: Existing RfCs for the acid gases are insufficient to form the basis for a § 112(d)(4) standard for ICIBPH emissions of these pollutants.

EPA asserts that in previous rulemakings it has relied on the RfC for HCl as the basis for establishing an alternative approach to regulating HCl or other acid gases for which it has been designated a surrogate. 75 Fed. Reg. at 32,030-32,031. EPA acted unlawfully in doing so in those rules, and it is equally incorrect here to suggest that the existing RfC is an "established health threshold" that could offer sufficient support for an alternative regulatory approach for HCl, whether as a surrogate or not. Nor can the existing RfCs for other acid gases (where they exist) be used in this way.

An inhalation RfC represents the air-related toxicity value for a noncancer health endpoint associated with exposure to an air toxic, and is expressed in weight of the toxic per volume of air (mg/m3). [Footnote: See U.S. EPA, “A Review of the Reference Dose and Reference Concentration Processes. Risk Assessment Forum, Washington, DC” (2002). EPA/630/P-02/002F. Available at: http://www.epa.gov/ncea/iris/RFD FINAL1.pdf.] The inhalation RfC provides a continuous inhalation exposure estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. The inhalation RfC considers toxic effects for both the respiratory system (a portal of entry) and effects peripheral to the respiratory system (extra-respiratory or systemic effects). An RfC can be derived from a ‘no observed adverse effect level’ (NOAEL), ‘lowest observed adverse effect level’ (LOAEL), or benchmark dose, with uncertainty factors generally applied to reflect limitations of the data used. [Footnote: See U.S. EPA, “A Review of the Reference Dose and Reference Concentration Processes. Risk Assessment Forum, Washington, DC” (2002). EPA/630/P-02/002F. Available at: http://www.epa.gov/ncea/iris/RFD FINAL1.pdf.] Reference values may also be derived for acute (?24 hours), short-term (>24 hours, up to 30 days), and subchronic (>30 days, up to approximately 10% of the life span) exposure durations, all of which are derived based on an assumption of continuous exposure throughout the duration specified. RfDs and RfCs are generally used in noncancer health assessments.

Table VI-1 summarizes U.S. EPA (via the Integrated Risk Information System, IRIS [Footnote: Available at http://www.epa.gov/ncea/iris/index.html.] and California Environmental Protection Agency (Cal EPA) toxicity values [Footnote: Available at http://www.oehha.ca.gov/air/allrels.html.] for the acid gases hydrogen chloride (HCl), chlorine (Cl2), hydrogen fluoride (HF), and hydrogen cyanide (HCN). IRIS is a human health assessment program that provides high-quality science-based human health assessments to support EPA’s regulatory activities. IRIS is prepared and maintained by the EPA’s National Center for Environmental Assessment within the Office of Research and Development. [Footnote: Animal studies can form the basis for these thresholds, as is clear from Table VI-1. To account for the fact that humans may be more or less sensitive than the test animal, a 10-fold uncertainty factor is usually applied to the NOAEL. This uncertainty factor is called the "interspecies uncertainty factor." An additional 10-fold uncertainty factor, the "intraspecies uncertainty factor," is usually applied to account for the fact that some humans may be substantially more sensitive to the effects of substances than others. Additional uncertainty factors may also be applied. If studies using human subjects are the basis of a RfC, then the interspecies uncertainty factor can be reduced to as low as 1, but generally the 10-fold intraspecies uncertainty factor is retained.] IRIS contains toxicity values for noncancer and cancer endpoints. In addition, Table VI-1 contains Cal EPA toxicity values, which are promulgated for use in California by the state’s environmental agency, but which are not necessarily endorsed or adopted (“established”) by U.S. EPA. Thus, while Cal EPA values are presented here to indicate the acid gases for which one well-regarded governmental agency has determined that enough toxicity information is available to set an exposure threshold, that fact does not mean that the Cal EPA values are “established” for the purposes of § 112(d)(4).

As noted above, the “established health threshold” must be based on a NOAEL, in order to be sufficient under §112(d)(4). A NOAEL is the highest concentration where no adverse effect is observed in the most sensitive health endpoint among all studies examined. The fact that there is a NOAEL for a set for a particular health endpoint for a pollutant does not mean that there are no other health endpoints affected by exposure to that pollutant, just that other health endpoints do not occur at the concentration seen for the NOAEL of the most sensitive endpoint. If effects are observed at all dose levels tested, then the smallest dose tested, the Lowest Observed Adverse Effect Level (LOAEL) is used to calculate the RfC. An additional uncertainty factor usually is applied in these cases, since the NOAEL, by definition, would be lower than the LOAEL had it been observed.

As table VI-1 demonstrates, however, the existing RfCs for both HCN and HCl are based on studies providing 'LOAEL values, as no appropriate studies providing NOAEL values are available. These RfCs also are "inhalation RfCs" – that is they represent the health risk and toxicity associated with the inhalation pathway of exposure only. But for these pollutants, there are other exposure pathways (the skin and eyes for example) by which health effects can occur. So, even if these RfCs were set on the basis of a NOAEL (which they are not), they would be an inadequate basis for §112(d)(4) standard setting. Additionally, no RfC is available for Cl2 at all, and HF is not among the 540 substances listed within IRIS, so no RfC is available for that acid gas. Furthermore, in evaluating the evidence that is available, for HCl and HCN, EPA states that they have "low confidence" in the RfC values. Inhalation RfCs exist only for two of the acid gases emitted by ICIBPH, HCl and HCN, and both of these RfCs reflect only studies of chronic exposures.

Comment Excerpt Number: 63

Comment: EPA has acknowledged that exposure to HCl does damage people's health by conceding that it causes "corrosive tissue damage." 71 Fed. Reg. 76,542. Although EPA has claimed in the past that such damage does not constitute "adverse effects" because the tissue damage "does not exceed an organism's ability to repair it" ? i.e., is not permanent or fatal, id. ? that argument was preposterous, and commenters hope that EPA no longer even entertains it. Damage to an "organism's" tissue — e.g. the lung tissue of a child — is an adverse health effect. Congress did not intend EPA to invoke § 112(d)(4) unless it was established that there would be no adverse health effects and, a fortiori, did not intend the agency to do so when it knew that there would be adverse health effects.

As noted above, in evaluating human health risk for noncancer endpoints, it is equally important to consider short-term exposures as well as long-term/chronic exposure to these emissions. Moreover, health effects depend upon both exposure and toxicity, and for acute effects, HF and HCN are more toxic on a weight/volume basis than HCl. The Cal EPA sets an acute reference exposure level (1 hour exposure) (REL) as 2.1 mg/m3 for HCl, 0.21 mg/m3 for Cl2, 0.24 mg/m3 for HF, and 0.34 mg/m3 for HCN. Therefore, Cl2, HF, and HCN are approximately 10-fold more toxic than HCl on a weight-standardized basis for short-term exposures. For these reasons, as well, unless Cl2, HF, and HCN are always present at concentrations that are at least 10-fold lower than HCl, even for short (1-hour) durations (a point on which EPA does not have information in the record for this rulemaking), only separate health-based thresholds, established for each acid gas, could ever be justified.

Respiratory effects (the endpoint of most concern for HCl, Cl2, and HF but not HCN) are likely after short-term exposures to high concentrations of acid gases. EPA asserts that it has little information on the peak short-term emissions of HCl from boilers, however. Were the existing RfCs used as the basis for a 112(d)(4) alternative standard, compliance with the health-based threshold would therefore be based on long-term average exposures. Because boilers are not run constantly, and because there are a wide variety of fuels burned (even at the same boiler), it is likely that intermittent peak exposures that greatly exceed the long-term average exposures for the (fuel-dependent) acid gases could occur. Lack of data on exactly what these intermittent peak exposures might be, however, is not sufficient reason to adapt a threshold based solely on chronic exposures.

Comment: EPA's IRIS evaluates cancer risks through a two-step process, which first evaluates whether a pollutant is carcinogenic, and then, if so further describes its toxicity. The first step uses a cancer weight-of-evidence descriptor to describe a substance's potential to cause cancer in humans, and the conditions under which the carcinogenic effects may be expressed. Under the EPA's 2005 guidelines for carcinogen risk assessment, a narrative approach is used to characterize carcinogenicity. [Footnote: U.S. EPA (2005). Guidelines for Carcinogen Risk Assessment. U.S. Environmental Protection Agency, Washington, DC, EPA/630/P-03/001F, 2005. Available at: http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=116283.] Five standard weight-of-evidence descriptors (Carcinogenic to Humans, Likely to Be Carcinogenic to Humans, Suggestive Evidence of Carcinogenic Potential, Inadequate Information to Assess Carcinogenic Potential, and Not Likely to Be Carcinogenic to Humans) are used as part of the narrative.

In the second IRIS step, for pollutants found to be carcinogenic at step 1, cancer slope factors (for oral exposures) and unit risks (for inhalation exposures) are used to estimate the risk of cancer associated with exposure to a carcinogenic or even a potentially carcinogenic substance. A unit risk is defined as the upper-bound, approximating a 95% confidence limit, of excess lifetime cancer risk estimated to result from continuous exposure to an agent at a concentration 1 mg/m3 in air. The interpretation of unit risk for a substance in air would be as follows: if unit risk = 2 x 10-6 per mg/m3, one might expect, as an upper bound estimate of risk, that based on a lifetime daily exposure to 1 mg/m3 of the substance in air, up to 2 excess cancer cases may develop per 1,000,000 exposed individuals.

It is notable that none of the four acid gases examined, HCl, CL2, HF, or HCN, has undergone a complete evaluation and determination of human carcinogenic potential under the IRIS program. As described above, this absence of information does not provide evidence that there is an absence of risk. Because § 112(d)(4) requires any alternative to a MACT standard to be based on both "no adverse effects" and an "ample margin of safety," the incomplete nature of this evaluation makes a §112(d)(4) standard unavailable for these pollutants.

The California EPA, under its Office of Environmental Health Hazard Assessment (OEHHA), conducts health risk assessments of chemical contaminants found in air, including those identified as toxic air contaminants under California's Air Toxics Hot Spots Act. Assessments can include development of Cancer Potency Factors to assess the cancer risk from carcinogens in air, and development of Reference Exposure Levels (RELs) to assess noncancer health impacts. Cal EPA has set both chronic RELs and acute RELs for the four acid gases considered in this rulemaking [see Table VI-1]. These limits are not U.S. EPA limits, however, and just as for the EPA RfCs, they do not include cancer risk assessments for these pollutants.

Comment: The purpose of the HBE provision of the CAA is to allow EPA to focus more stringent MACT controls on non-threshold HAPs (those that could pose some level of adverse health effects at any non-zero concentration) than HAPs with thresholds, for which the level of incremental concentration from a source could pose potential health consequences. By providing a special provision for threshold HAPs that likely pose little or no potential adverse health effects, the CAA allows EPA to consider limiting the burden on regulated sources with HAP emissions that pose little or no health hazard. Some of the HAPs targeted by the Boiler MACT, such as the acid gases, hydrogen chloride (HCl), chlorine (Cl2), hydrogen fluoride (HF) and hydrogen cyanide (HCN), as well as metals such as manganese (Mn) meet the requirements for classification as threshold pollutants. Therefore, if the associated incremental ambient concentrations of these threshold pollutants as a result of emissions from a regulated source are sufficiently low, they would qualify for alternative MACT provisions under 112(d)(4).

Section 112(d)(4) does not specify how EPA should "consider threshold levels, with an ample margin of safety" in developing alternative MACT requirements. In the Pulp and Paper MACT and in the 2004 Boiler MACT, EPA maintained that that application of this CAA section is met

if the incremental exposure concentration from subject MACT sources at a facility is less than established health effects thresholds. The “margin of safety” is built into the means by which:
* Emissions and associated exposure concentrations are characterized;
* Health effects thresholds are derived; and
* Dispersion models estimate exposure.

CAA Section 112(d)(4) does not apply to HAPs from other source categories at a facility or background concentrations, as the CAA explicitly directs EPA to address residual issues subsequent to the initial MACT setting process under CAA Section 112(f)(c).
HCl typically comprises about 80% or more of acid gas emissions from boilers, with 20% or less comprised of HF. In terms of developing Health-Based Emission Limits (HBEL), it is appropriate to consider EPA’s concept of Target Organ Specific Hazard Index (TOSHI), where the potential for health consequences for various HAPs with similar types of health effects are assumed to be additive. Toxicological studies for HCl and HF indicate that they have the same mode of action as irritant acid gases. Given that HCl and HF concentrations are simultaneously present in flue gas, it may be appropriate to consider acute and chronic effects of these two HAPs collectively in evaluating peak short term (e.g., 1-hour) and long-term (e.g., annual average) exposure concentrations. This concept could be readily incorporated by computing a toxicity-weighted emission rate of HCl that accounts for HCl and HF emissions and their corresponding health effects benchmarks.
We noted that EPA’s suggestion in the 2010 proposed rule that HF and HCN could materially contribute to health risk runs directly counter to the following statement that the agency made in the preamble to the 2004 Boiler MACT Final Rule (69 FR 55244) when it stated that its research indicated that health risks from HF and HCN emissions from boilers are considered to be insignificant.

“Facilities attempting to utilize the health-based compliance alternative for HCl will not be required to evaluate emissions of other inorganic HAP except for chlorine. We conducted an assessment of boiler emissions and determined that, of the acid gas HAP controlled by scrubbing technology, chlorine is responsible for the great majority of risk and HCl is responsible for the next largest portion of the total risk. The contributions of other HAP, including hydrogen fluoride, to the total risk were negligible. Therefore, facilities attempting to demonstrate eligibility for the health-based compliance alternative for HCl, either by conducting a lookup table analysis or by conducting a site specific compliance demonstration, must include emission rates of chlorine and HCl from their boilers. We do not expect hydrogen cyanide emissions from boilers covered under the final rule.”
If EPA has conducted new research that refutes this former finding, it is imperative that this research be brought to light.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment Excerpt Number: 136

Comment: In the proposed rulemaking, EPA concluded that the information available at this time is insufficient to establish health-based emission standards for HCl or the other acid gases. In the 2004 Boiler MACT EPA concluded that HCl was a threshold pollutant for which CAA Section 112(d)(4) should be applied and there are many other historical precedents where EPA has considered HCl a threshold pollutant. Some of those precedents include: 1) National mission Standards for Hazardous Air Pollutants: Final Standards for Hazardous Air Pollutants for Hazardous Waste Combustors (Phase I Final Replacement Standards and Phase II); Final Rule; 2) National Emission Standards For Hazardous Air Pollutants; Proposed Standards For Hazardous Air Pollutants From Chemical Recovery Combustion Sources At Kraft, Soda, Sulfite, And Stand-Alone Semichemical Pulp Mills; 3) National Emission Standards for Hazardous Air Pollutants From the Portland Cement Manufacturing Industry; Proposed Rule; 4) National Emission Standards for Hazardous Air Pollutants: Chlorine and Hydrochloric Acid Emissions From Chlorine Production.

Thus, the recent change in EPA's position appears not to be based on changes in the underlying scientific evidence since 2004 but rather a shift in policy. In this proposed rulemaking, EPA interprets section 112(d)(4) to allow additional factors beyond any established health threshold, such as cumulative and ecological effects, to be weighed in making a judgment whether to set a standard for a specific pollutant based on the threshold. This interpretation of the CAA represents a significant and unexplained departure from previous MACT rulemakings and from EPA's prior decision to adopt health based emissions limitation in the 2004 industrial boiler MACT rule. The Agency has made a 180 degree turn that is not supported by the record and not scientifically justified.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: HCl, other acid gases and some metal HAPs, such as Mn qualify as threshold pollutants and, therefore, they should be considered under section 112(d)(4). [SEE submitted (page 169) for a list of reference for HBEL comments.] Supporting evidence includes identification of a threshold dose below which adverse effects do not occur, lack of evidence for carcinogenicity and consideration of toxicological interactions among acid gases and potential for additive effects. In addition, demonstration of a common mode of action amongst the various HAPs would support the notion of applying a single 112(d)(4) standard for acid gases.

Table 1 summarizes threshold for acute and chronic health effects data on threshold doses for HCl, Cl_2, hydrogen cyanide (HCN), HF, and Mn. Information supporting the existence of health effects thresholds for each HAP is provided below along with a discussion of whether the HAPs have similar modes of action.

Critical Target Organ

The critical target organ for acute toxicity of HCl is the upper respiratory system (sore throat, nasal discharge), lower respiratory system (pulmonary function, cough, chest pain), and eyes. The target organ for chronic toxicity is also the respiratory system.

Mechanism of Action

On contact with moisture, HCl dissociates almost completely. The hydrogen ions combine with water to form hydronium ions ($H3O+$), which can cleave organic molecules and cause cell death. Thus, the adverse effects associated with HCl exposure are due to direct contact irritation of tissues at the portal of entry and persistent cellular injury in the affected tissue.

Evidence of Threshold

An acute threshold has been established. A chronic threshold has not been established. However, data on chronic toxicity of HCl are very limited and all studies located in the literature have used the Lowest Observed Adverse Effect Level (LOAEL) as the lowest dose in the dosing regimen. Therefore, the failure to identify a chronic threshold is not an indication that no threshold exists, but rather an indication that data on chronic effects from HCl are very limited. HCl is typically an acute exposure concern but the chronic RfC is usually limiting in exposure assessments. However, controlling short-term peak exposures naturally has the dual benefit of also reducing long-term exposures. In addition to the general lack of toxicological studies suggesting that HCl could be a potential carcinogen (see below), the listing of health thresholds for HCl by the Environmental Protection Agency (EPA), Agency for Toxic Substance Disease Registry (ATSDR), California EPA, and the World Health Organization in the public domain has established that HCl is a threshold pollutant.

Evidence of Carcinogenicity

No pre-neoplastic or neoplastic nasal lesions were observed in a 128-week inhalation study with SD male rats at 10 ppm HCl gas. No evidence of treatment related carcinogenicity was observed in other animal studies performed by inhalation, oral or dermal administration. In humans, no association between HCl exposure and tumor incidence has been observed.

Cumulative Exposure

There is little evidence that the general public is exposed routinely to measurable quantities of gaseous chlorine and/or HCl. Even the HCl produced during the combustion of fossil fuels or the incineration of solid waste apparently lasts too short a time in the un-reacted state to pose a significant health risk (IPCS, 1982). However, HCl does affect the same target organ system (respiratory system) as hydrogen fluoride (HF) and, therefore, it is possible that the effects of HCl and HF could be additive.

Critical Target Organ

The critical target organ for the acute toxicity of Cl2 is the upper respiratory system (transient respiratory irritation), lower respiratory system (slight alterations in pulmonary function tests), and the eyes. The target organ for chronic toxicity is also the respiratory system.

Mechanism of Action

Cl_2 is a strong oxidizer that hydrolyzes in water forming HCl and hypochlorous acid. Cl_2 gas has been shown to be 33 times more potent as a sensory irritant in mice than HCl (Barrow et al. 1977), The assumption is that products of the reaction of Cl_2 with water are able to interact with functional groups in components from cells in the respiratory epithelium. At low concentrations, only sensory receptors are affected, triggering only changes in respiratory dynamics, but higher concentrations produce frank tissue damage due to disruption of cellular components (ATSDR, 2007).

Evidence of Threshold

The effects of acute-exposure to Cl_2 have been well characterized in humans and animals. Collectively, the results suggest that brief exposures to concentrations of Cl_2 less than 0.5 ppm do not cause sensory irritation or significant alterations in pulmonary function tests, but exposure to 1 ppm or greater can induce transient respiratory and eye irritation and slight alterations in pulmonary function tests (Anglen 1981; D'Alessandro et al. 1996; Rotman et al. 1983; Schins et al. 2000; Shusterman et al. 1998, 2003). There is no information regarding chronic-duration exposure of the general population to chlorine because this type of exposure occurs only in occupational settings. There are few studies of chronically exposed workers that were not also subjected to acute episodes of high exposure or "gassing" incidents. However, a chronic threshold based on nasal lesions has been established in monkeys (Klonne et al. 1987).

Evidence of Carcinogenicity

No studies on the carcinogenic effects of Cl_2 in humans and only a few animal studies were located in the literature. All of the animal carcinogenicity studies listed on the Chemical Carcinogenesis Research Information System were negative and no positive studies were listed on the Carcinogenic Potency Project at http://potency.berkeley.edu/chemicalsummary.html. Co-carcinogenic properties (i.e., some studies suggest that Cl_2 can promote the carcinogenicity of other compounds) of Cl_2 in animals have been examined, but the results are mixed, with one study resulting in cancer in a single mouse and another study causing a 40% decrease in the number of skin cancers in initiated mice. Study results on genotoxicity of Cl_2 have also been mixed. Neither, the EPA, the International Agency for Research on Cancer (IARC), or the Department of Health and Human Services (DHHS) have classified Cl_2 gas as to its carcinogenicity. Although EPA has not developed a formal evaluation of the potential for Cl_2 carcinogenicity, the evaluation by the International Agency for Research on Cancer stated that there was inadequate evidence for carcinogenicity in humans or experimental animals and thus concluded that Cl_2 is not classifiable as to its carcinogenicity to humans. Other rules (e.g., Final Standards for Hazardous Air Pollutants for Hazardous Waste Combustors (Phase I Final Replacement Standards and Phase II); Final Rule; 2) National Emission Standards For Hazardous Air Pollutants) have evaluated Cl_2 only with regard to non-cancer effects. In the absence of specific scientific evidence to the contrary, it has been EPA's policy to classify non-carcinogenic effects as threshold effects.

Cumulative Exposure

There is little evidence that the general public is exposed routinely to measurable quantities of gaseous Cl_2. However, Cl_2 does affect the same acute target organ system (respiratory system) as HCl and hydrogen fluoride (HF) and the same chronic target organ system (respiratory system) as HCl, Therefore, it is possible that the acute effects of Cl2, HCl and HF could be additive and the chronic effects of Cl2 and HCl could also potentially be additive.

1. Hydrogen Cyanide (HCN)

Critical Target Organ

The Central Nervous System (CNS) is the target organ for the acute health effects associated with HCN. The critical target organ for the chronic health effects of HCN is also the CNS, but long-term exposure can also affect thyroid function (CalEPA, 2008b).

Mechanism of Action

The mode of action of HCN toxicity is cytochrome oxidase inhibition, which prevents cellular utilization of oxygen. The cyanide ion blocks oxidative respiration, causing failure of oxygen usage with tissue hypoxia leading to metabolic acidosis.

Evidence of Threshold

An acute threshold has been established. A chronic threshold in humans has not been established. Data on chronic toxicity of HCN in humans (and animals) is very limited. However, a subacute inhalation NOAEL for HCN has been established in rabbits (CalEPA, 2008b). In addition to the lack of evidence that HCN is a potential carcinogen (see below), the listing of health thresholds for HCN by California EPA (CalEPA, 2008b) and many other organizations (e.g., Agency for Toxic Substance Registry [ATSDR], World Health Organization [WHO], National Institute of Public Health and the Environment, Bilthoven (The Netherlands), etc.) in the public domain has established HCN as a threshold pollutant.

Evidence of Carcinogenicity

Out of 20 mutagenicity studies summarized on the Chemical Carcinogenesis Research Information System (CCRIS) for sodium cyanide, there was not a single positive result (CCRIS, 2010). Therefore, available data indicate that HCN does not have mutagenic properties and is not considered to be a carcinogen. Free CN is not classifiable as to human carcinogenicity (IRIS, 2010).

Cumulative Exposure

HCN has a completely different mechanism of action than the other two acid gases on which comments have been requested (i.e., HCl and HF) and affects a different target organ system. While several studies indicate that chronic exposure of workers to low concentrations of cyanide can cause respiratory, cardiovascular, and thyroid effects, the acute effect on the CNS system occurs at lower concentrations than those at which the portal of entry (respiratory) effects occur. Because HCN has a different mode of action than HCl and HF, it is not a candidate for a limit that addresses the combined effects of multiple acid gases.

2. Hydrogen Fluoride (HF)

Critical Target Organ

The critical target organ for acute health effects of HF is the upper respiratory system (irritation), with symptoms such as coughing, choking, and chills, followed by pulmonary edema, which may occur with cough, chest tightness, rales, and cyanosis after an asymptomatic period of one to two days (CalEPA, 2008a). The critical chronic target organs include bone and teeth (skeletal/dental fluorosis), as well as the upper respiratory system (pulmonary hemorrhage) (CalEPA, 2008b).

Mechanism of Action The acute respiratory effects of HF are the result of dehydration and corrosion of tissues mediated by free hydrogen ions (CalEPA, 2008a). The respiratory system is also listed as one of the critical target organs for chronic toxic effects of HF; however, respiratory effects result from higher exposure levels than required for fluorosis (Hodge and Smith, 1977). Presumably, direct contact irritation of tissues at the portal of entry and persistent cellular injury in the affected tissue are responsible for the chronic respiratory effects of HF. In addition, the dissociated fluoride ion is also capable of complexing certain bivalent cations, primarily calcium and magnesium, which interferes with calcium metabolism and causes cell destruction (CalEPA, 2008b) and fluorosis upon chronic exposure. Skeletal fluorosis is considered to be the critical target organ for chronic exposure since this effect is seen at lower concentrations than the respiratory system effects.

Evidence of Threshold

Both acute and chronic threshold doses have been established. In addition, since lower doses of fluoride have a beneficial or nutritional effect, a threshold type of response for adverse effects is clearly expected (CalEPA, 2008b). In addition to the general lack of evidence that HF is a carcinogen in humans (see discussion below), the listing of health thresholds for HF by California EPA (CalEPA, 2008b) and many other organizations (e.g., Agency for Toxic Substance Registry [ATSDR], World Health Organization [WHO], etc.) in the public domain has established HF as a threshold pollutant.

Carcinogenicity

Several authors have suggested the potential mutagenicity of HF or sodium fluoride, although EPA and National Research Council have concluded that the mutagenicity of HF in man has not been demonstrated (EPA, 1998). According to the National Toxicology Program, "the preponderance of evidence" from laboratory in vitro (i.e., cell culture) studies indicate that fluoride is a mutagenic compound in laboratory studies. Some substances that are shown to be mutagens in laboratory studies, are also carcinogens. In some cases, “the overall significance of the in vitro fluoride transformation data are subject to question" (NRC, 1993) because the cells used in some of the laboratory studies are unusually sensitive to the induction of transformation. In addition, the concentrations of fluoride causing mutagenic damage in the in vitro studies is higher than the concentrations found in human blood. More importantly, no specific epidemiological evidence is available for evaluation of the potential carcinogenicity of HF or other fluoride compounds in humans. Increased rates of cancer have been reported in workers in several industries involving exposure to mixtures containing fluorides, but fluoride could not be specifically implicated as the cause of the cancer in any of these studies (EPA, 1998). The potential carcinogenic potential of fluorides in drinking water has also been investigated. The International Agency for Research on Cancer (IARC) concluded that when differences in demographics, degree of industrialization, and other social factors are accounted for, the studies provide no evidence that an increase in the level fluorides in drinking water is associated with an increase in cancer mortality (EPA, 1998). Therefore, there is a lack of evidence to suggest that HF or other fluoride compounds are carcinogenic.

3. Manganese (MN)

Critical Acute Target Organ

Mn toxicity has been reported through occupational (e.g. welder) and dietary overexposure and is evidenced primarily in the Central Nervous System, although lung, cardiac, liver, reproductive and fetal toxicity have been noted. The CNS is considered the critical target organ for the chronic toxicity of Mn (Crossgrove and Zheng, 2004). No information on acute toxicity of Mn could be located in the open scientific literature.

Mechanism of Action

Mn neurotoxicity results from an accumulation of the metal in brain tissue and results in a progressive disorder of the extrapyramidal system which is similar to Parkinson's disease. In order for Mn to distribute from blood into brain tissue, it must cross either the blood–brain barrier (BBB) or the blood–cerebrospinal fluid barrier (BCB). Brain import, with no evidence of export, would lead to brain Mn accumulation and neurotoxicity. The mechanism for the neurodegenerative damage specific to select brain regions is not clearly understood. Disturbances in iron homeostasis and the valence state of Mn have been implicated as key factors in contributing to Mn toxicity (Crossgrove and Zheng, 2004).

Evidence of a Threshold

Lower doses of Mn have a beneficial or nutritional effects, therefore, a threshold type of response for adverse effects is clearly expected. There is debate about where the threshold for Manganese falls, but several studies in the last two decades provide for determination of No Observed Adverse Effect Levels (NOAELs) for chronic neurological effects in workers. In addition to the lack of evidence that Mn is a carcinogen (see discussion below), the listing of health thresholds for Manganese by EPA, California EPA (CalEPA, 2008b) and the Agency for Toxic Substance Registry (ATSDR) in the public domain has established Manganese as a threshold pollutant.

Evidence of Carcinogenicity

Mn is listed in IRIS as Classification D (not classifiable as to human carcinogenicity) (IRIS, 2010). Although there are some mixed results, there are little data to suggest that inorganic Mn is carcinogenic.

1. Evidence for Thresholds

Hydrogen Chloride (HCl)

Based on the limited negative carcinogenicity data, and on knowledge of how chlorine reacts in the body, its likely mechanism of action, and its consideration as a threshold pollutant in numerous other rulemakings, HCl is presumptively considered to be a threshold pollutant.

Chlorine (Cl2)

Based on the thresholds established for Cl2, the lack of evidence for carcinogenicity, it's likely mechanism of action, and it's consideration as a threshold pollutant in numerous other rulemakings, Cl2 is presumptively considered to be a threshold pollutant.

Hydrogen Cyanide (HCN)

Based on the thresholds established for HCN, the lack of evidence for carcinogenity, and knowledge of how HCN reacts in the body, HCN is considered to be a threshold pollutant.

Hydrogen Fluoride (HF)

Based on the thresholds that have been established and lack of reliable data suggesting that HF is carcinogenic, HF is presumptively considered to be a threshold pollutant.

Manganese (Mn)

Lower doses of Mn have a beneficial or nutritional effects, therefore, a threshold type of response for adverse effects is clearly expected. In addition to the lack of evidence that Mn is a carcinogen (see discussion below), the listing of health thresholds for Manganese by EPA, California EPA (CalEPA, 2008b) and the Agency for Toxic Substance Registry (ATSDR) in the public domain has established Manganese as a threshold pollutant.

Proposed Toxicity Factors and Margins of Safety

Hydrogen Chloride (HCl)

It is proposed that the California EPA (CalEPA) acute Reference Exposure Level (REL) be established as the acute threshold dose and that the EPA RfC be established as the chronic threshold dose. The human studies on which the California acute REL is based were done with asthmatics, which represent a sensitive human subpopulation. Also, the chronic EPA RfC has a cumulative uncertainty factor of 300 (10 for extrapolation from a LOAEL to a NOAEL, 3 for interspecies variability, and 10 for intraspecies variability) built into it. Therefore, both the acute and chronic threshold values recommended for HCl provide an ample margin of safety for use in establishing emission standards under CAA112(d)(4).

Chlorine (Cl2)

It is proposed that the Agency for Toxic Substances and Disease Registry (ATSDR) acute Minimal Risk Levels (MRL) be established as the acute threshold dose. The acute no-observed-adverse-effect level (NOAEL) of 0.5 ppm was adjusted to account for continuous exposure (0.5 ppm x 8 hours/24 hours = 0.2 ppm). Although sensitive individuals were tested in some of the studies, an uncertainty factor of 3 was used to account for sensitive populations to arrive at the acute-duration inhalation MRL of 0.07 ppm (0.2 ppm/3). It is also proposed that the ATSDR chronic MRL be established as the chronic threshold dose. An uncertainty factor of 30 (3 for extrapolation from animals to humans with dosimetric adjustment and 10 for human variability) was applied to the lower 95% confidence limit predicted exposure concentration associated with a 10% extra risk to arrive at the chronic-duration inhalation MRL of 0.00005 ppm for Cl2. Therefore, both the acute and chronic threshold values recommended for Cl2 provide an ample margin of safety for use in establishing emission standards under CAA 112(d)(4).

Hydrogen Cyanide (HCN)

It is proposed that the California EPA (CalEPA) acute Reference Exposure Level (REL) be established as the acute threshold dose and that the EPA RfC be established as the chronic threshold dose. The California acute REL has a cumulative uncertainty factor of 100 (10 for interspecies variability and 10 for intraspecies variability) built into it. In addition, the acute studies were done on primates, which represent the species most similar to man, thereby reducing uncertainty regarding toxic response. Also, the chronic EPA RfC has a cumulative uncertainty factor of 1000. A factor of 10 is used for sensitive human subpopulations, a factor of 10 is used for the lack of a NOAEL, and partial factors of 3 each are used for deficiencies in the database (lack of chronic and multigenerational reproduction studies) and for less than chronic duration. Therefore, both the acute and chronic threshold values recommended for HCN provide an ample margin of safety for use in establishing emission standards under CAA112(d)(4).

Hydrogen Fluoride (HF)

It is proposed that the CalEPA acute and chronic RELs be established as threshold doses for HF. Both the acute and chronic California RELs for HF incorporate a cumulative uncertainty factor of 10 to account for variability in human responses (intraspecies variability) to inhalation exposure to HF. While this safety factor is not as large as some, both threshold values are judged to provide an ample margin of safety for use in establishing emission standards under CAA112(d)(4) since the studies were conducted in human populations, thereby eliminating much of the uncertainty regarding toxic responses. The chronic REL in particular is judged to be amply conservative because the human population consisted of fertilizer plant workers who were no doubt exposed to many other chemicals simultaneously.

Manganese (Mn)

No acute toxicity criteria for Mn were located in the open scientific literature. It is proposed that the EPA RfC be established as the chronic threshold dose. The chronic EPA RfC has a cumulative uncertainty factor of 1000. This uncertainty factor reflects 10 to protect sensitive individuals, 10 for use of a LOAEL, and 10 for database limitations reflecting both the less-than-chronic periods of exposure and the lack of developmental data, as well as potential but unquantified differences in the toxicity of different forms of Mn. Therefore, the chronic threshold value recommended for Mn provides an ample margin of safety for use in establishing emission standards under CAA112(d).

Comment Excerpt Number: 139

Comment: Both acute and chronic exposure to HCl, Cl2 and HF affect the respiratory system and the pollutants cause respiratory irritation by similar mechanisms of action (direct contact irritation of tissues at the portal of entry and persistent cellular injury in the affected tissue). However, the critical effect on which the chronic toxicity criterion for HF is based is skeletal fluorosis, which occurs at lower doses than the reported respiratory effects (Hodge and Smith, 1977). Therefore, it is recommended that a combined acute HBEL for HCl, Cl2, and HF and a combined chronic HBEL for HCl and Cl2 be established. However, a separate chronic 112(d)(4) HBEL for HF is recommended.

While chronic exposure of workers to low concentrations of cyanide can cause respiratory symptoms, effects on the CNS system occur at lower concentrations than those at which the portal of entry (respiratory) effects occur. In addition, HCN has a completely different mechanism of action than HCl and HF. Therefore, HCN is not a good candidate for inclusion if a combined acid gas standard is derived. Therefore, establishment of a single acute 112(d)(4) HBEL for HCN is recommended. Although the critical target organ for Mn is the CNS, Mn has a completely different mechanism of action from HCN. Since Mn has a different mechanism of action from HCN and affects a different target organ than HCl and HF, establishment of a separate chronic 112(d)(4) HBEL for Mn is indicated as well.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment Excerpt Number: 15

Comment: An ample margin of safety has been demonstrated.

When setting a health-based limit, the Agency is required to ensure that the level will be protective of human health, with an ample margin of safety. Traditionally, that level has been the RfC which, as the Agency knows, contains multiple levels of added safety. For example, the RfC for HCI is 20 ug/m3, 30 times lower than the NOAEL. By setting a site-specific standard at a hazardous index (ratio of the exposure at the fence line to the reference concentration) to 1.0, EPA will have demonstrated an ample margin of safety.

Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 200

Comment: Implementation of HBCAs.
Some of the HAPs targeted by the Boiler MACT, such as hydrogen chloride (HCl), chlorine gas (Cl2), hydrogen fluoride (HF) and hydrogen cyanide (HCN) meet the requirements for classification as threshold pollutants. Therefore, if the associated incremental ambient concentrations of these threshold pollutants as a result of emissions from a regulated source are sufficiently low, they would qualify for an HBCA under Section112(d)(4).

CIBO believes that the Boiler MACT should include HBCAs that take the form of a limited number of alternative HAP emissions limits based upon facility specific emissions of HCl, Cl2, HF and HCN and modeling against references concentrations provided by EPA using a health index.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 202

Comment: Hydrogen Cyanide Emissions are Insignificant And Should Not Factor Into an HBCA.
As discussed above, CIBO strongly believes that an HBCA needs to be established to allow units covered by the Boiler MACT to comply with the rule's requirements and timetables. However, in setting this HBCA, CIBO believes that hydrogen cyanide (HCN) should not be included, because HCN emissions make insignificant contributions to any relevant health risk.

EPA has long recognized that the chief acid gas HAPs emitted from most industrial facilities are chiefly HCl and HF. In its 2004 response to comments on the prior Boiler MACT rule, EPA stated: "We conducted an assessment of boiler emissions and determined that . . . the contributions of other HAP [aside from HCl and chlorine] . . . to the total risk were negligible." 69 FR 55218-44 (Sept. 13, 2004). Thus, at that time, EPA commented that it did not expect HCN emissions from boilers to be covered under that rule. Id.

A review of TRI 2008 data (excluding EGUs, chemical plants, and metal mining) indicates that this conclusion has not changed over the last few years, since only 0.3% of HAP gas emissions are HCN. The Proposed Rule reaches similar results. The percentages EPA has provided for HAP emissions in the Proposed Rule – which do not include HCN emissions – sum to 99%, indicating that HAP emissions are insignificant. 75 FR 32011. Because HCN emissions are insignificant in assessing health based risk, they should not factor into HBCA compliance.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 9

Comment: As a practical matter, 112(d)(4) applies to non-carcinogenic HAPs [Footnote: Almost without exception, EPA assumes a linear, no-threshold dose-effect relationship for HAPs that are classified as carcinogens.] for which EPA has established a health threshold such as a reference concentration ("RfC") or a reference dose ("RfD"). EPA defines a reference concentration in its IRIS database as "[a]n estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime." [Footnote: The definition for a reference dose is essentially the same except it focuses on exposures by pathways other than inhalation.] Thus, human exposures to a HAP at levels below its RfC are considered "safe" particularly given the uncertainty factor that EPA includes as part of its derivation of a RfC. Congress' inclusion of 112(d)(4) in the 1990 CAA Amendments indicates an intent to retain the health endpoint of the original 112 -- protection of public health with an ample margin of safety. If the emissions of a given HAP from all sources in a source category are at a level where public health is protected with an ample margin of safety, then there is no practical need for or benefit from further regulation.

Duke Energy believes that in many cases, HAP emissions from industrial boilers will pose minimal risk to human health or the environment. Incorporating this option into the final rule would provide significant cost savings by foregoing the requirement for add-on controls on industrial boilers whose emissions do not exceed health benchmarks. At the same time, this mechanism would ensure that industrial boilers whose emissions do exceed these benchmarks are controlled. As a result, Duke Energy believes EPA can and should set health-base standards under 112(d)(4) when facts support its use.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 67

Comment: On Page 32031 of the preamble, EPA concludes, "we do not have sufficient information at this time to establish what the health-based emission standards would be for HCl or other acid gases." EPA invites public comment on EPA's information and conclusion. EPA could rely on information such as the Texas Commission on Environmental Quality (TCEQ) Effects Screening Levels (ESL's) to establish concentration-based limits for each of these pollutants. ESL's are based on data concerning health effects, odor/nuisance potential, and effects on vegetation, thus satisfying the criteria for both health concerns and also impact on the surrounding environment. These values are also periodically reviewed and updated by a rigorous process defined by TCEQ. Dow believes that these levels are set at a level where no observable effects occur, with an ample margin of safety.

[See submittal for TCEQ's ESL's for the air contaminants of concern.]

Note: TCEQ's annual average value for HCl of 7.5 micrograms per cubic meter is less than EPA's chronic reference concentration of 20 micrograms per cubic meter noted on Page 32031 of the preamble.

Comment: As part of our toxics permitting process, NC DAQ routinely applies a health risk-based methodology similar to what EPA is requesting, including:
Establishing health risk-based concentration thresholds for toxic air pollutants, known as

Acceptable Ambient Levels (AALs), which represent a level "below the concentration that would produce adverse health effects in sensitive subgroups of the general population." For example, under NC air toxics rules, HCl is considered an acute irritant with an AAL of 0.7 milligrams per cubic meter (mg/m3) for 1-hour exposure. Similarly, hydrogen fluoride (HF) has an AAL of 0.25 mg/m3 for 1-hour exposure, but also an AAL of 0.03 mg/m3 for 24-hour exposure.

Compiling facility-specific toxic air pollutant emissions from each permitted source,

Collecting emission release parameters and coordinates for each emission source
Obtaining facility geospatial data and building downwash parameters (tier heights and footprint coordinates), and

Performing dispersion. modeling, using EPA approved procedures, to determine air pollutant concentrations at the property boundaries.

Using the EPA Human Exposure Model, NC DAQ conducted a statewide risk assessment screening study of 1800 facilities to evaluate cancer and non-cancer health risks from combustion sources and boiler emissions.2

Comment Excerpt Number: 6

Comment: EPA should develop MACT controls on non-threshold HAPs (those that could pose some level of adverse health effects at any non-zero concentration) and HAPs with thresholds, for which the level of incremental concentration from a source could pose potential health consequences. Some of the HAPs targeted by the Boiler MACT, such as the acidic gases, hydrogen chloride (HCl), hydrogen fluoride (HF) and hydrogen cyanide (HCN), and metals such as manganese (Mn) meet the requirements for classification as threshold pollutants. Until such risk characterized health assessment is completed for these acidic gas pollutants, EPA should consider limiting the burden on regulated sources by providing a special provision for threshold HAPs that pose little or no potential adverse health effects.

Comment: In the preamble to the 2004 Boiler MACT, the EPA correctly made the case that hydrogen chloride (HCl) and manganese (Mn) are threshold pollutants subject to consideration for a Health Based Compliance Alternative (HBCA) under Section 112(d)(4). The HBCA allows the EPA to minimize the probability that a source might have to incur significant regulatory burden and cost to install and operate a pollution control device that provides minimal or no demonstrated health benefit, and it specifically applies to pollutants with established thresholds below which no adverse health effects occur. HCl and Mn are boiler HAPs with established thresholds or evidence that effects are very limited. Considerable research has demonstrated that there is no evidence of carcinogenicity for either substance.

Comment: Acid gases and manganese are threshold pollutants and not carcinogenic.
In the original 2004 Boiler MACT rule, EPA determined that hydrogen chloride (HCl) and manganese (Mn), are threshold pollutants. There is no scientific data to suggest that HCl is carcinogenic and very little data that Mn is carcinogenic. The science for this determination has not changed since 2004 and thus EPA’s conclusion remains valid for this proposed rule.

The other major acid gases, hydrogen fluoride (HF) and HCN are also threshold pollutants as described fully in the AF&PA comments. There is also a lack of evidence that HF, other fluoride compounds or HCN are carcinogenic.

Comment: In the newly proposed Industrial Boiler MACT, EPA acknowledges its authority under § 112(d)(4) to establish a health-based emissions limitation for threshold pollutants in lieu of a MACT emissions limitation. However, the Agency proposes not to establish any health based emissions limitations "[g]iven the limitations of the currently available information (i.e., the HAP mix where boilers are located, and the cumulative health impacts from co-located sources), the environmental effects of HCl, and the significant co-benefits of setting a conventional MACT standard for HCl."4 Nevertheless, EPA asks for comment on a wide range of issues related to the justification for setting health based emissions limitations and the method by which they should be set.

Ample scientific information supports a determination that HCl, hydrogen fluoride, hydrogen cyanide, and manganese are threshold pollutants and, thus, are eligible to be regulated under § 112(d)(4). In addition, the Agency has the technical tools and significant factual support for establishing health based emissions limitations for these HAPs that would provide the requisite ample margin of safety to health and the environment. Thus, health based emissions limitations are fully justified on scientific and technical grounds. EPA should set health based emission limitations for HAP acid gases and, like in the 2004 rule, a health based emissions limit for manganese, which should be implemented in conjunction with a Total Select Metal ("TSM") standard (where the TSM standard would be an alternative to the PM surrogate, and where a "TSM less manganese" option would be provided when a source elects to comply with the health based compliance alternative for manganese).

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 111

Comment: ACC Supports the Inclusion of Work Practices. Instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels (the "Gas 1" subcategory), EPA proposes to adopt work practices requiring an annual tune up of units that have a heat input capacity of less than 10MMBtu/h, and all units that combust natural gas and refinery gas (Gas 1 and Metal Process Furnaces Subcategories). For units larger than 100 mmBtu/hr, EPA explains that "the capital costs estimated for installing controls on these boilers and process heaters to comply with MACT limits for the five HAP groups is over $14 billion."[75 Fed. Reg. at 32025.] EPA further explains that:

[T]he need to employ the same emission control system as needed for the other fuel types would have the negative benefit of providing a disincentive for switching to gas as a control technique (and a pollution prevention technique) for boilers and process heaters in the other fuel subcategories. In addition, emission limits on gas-fired boilers and process heaters may have the negative benefit of providing an incentive for a facility to switch from gas (considered a "clean" fuel) to a "dirtier" but cheaper fuel (i.e., coal). It would be inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular, to adopt requirements that would result in an overall increase in HAP emissions.[Id.]

Response: We appreciate the input from the commenter. EPA is not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: Section 112(d)(4)'s Requirement to Set Any Health-Based Standards With "An Ample Margin of Safety" Requires Evaluation of Synergistic Health Effects, and From all HAP Emissions From the Industrial Facility, not the Boiler Alone.

EPA seeks comment on questions about whether there would be additive effects if individual section 112(d)(4) standards are established for each acid gas, and if so, how that effect could be simulated. 75 Fed. Reg. 32,032. The agency asserts that "[i]ndividual acid gas standards under section 112(d)(4) would likely be established using the hazard quotient (HQ) approach, under which we would develop the ratio of the maximum ambient level to the chronic threshold. However, this approach would not by itself account for potential toxicologic interactions. Since all of the acid gases are respiratory irritants, one way to account for potential toxicologic interactions of these pollutants would be the use of the hazard index (HI) approach, as described in EPA's "Guideline for the Health Risk Assessment of Chemical Mixtures." [Footnote: US EPA 2000. Supplementary Guidance for Conducting Health Risk Assessment of Chemical Mixtures. U.S. Environmental Protection Agency, Washington DC. EPA/630/R-00/002. Available at: http://www.epa.gov/nceawww1/pdfs/chem_mix/chem_mix_08_2001.pdf. This guidance replaced previous U.S. EPA "Guidelines for the Health Risk Assessment of Chemical Mixtures," 51 Fed. Reg. 34,014 (Sept. 24, 1986), available at: http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=22567.] Id. EPA requests comment on that approach, and on whether there are any other approaches to address such additive issues.

We assert that EPA's assumption that it can properly "address additive issues" in this way is not justified. Based on its Hazard Index approach, [Footnote: 75 Fed. Reg. at 32032 referencing "Guidance for the Health Risk Assessment of Chemical Mixtures" (no citation given), but see previous note.] and in the absence of studies explicitly addressing the toxicity of mixtures of HCl with other respiratory irritants, EPA is taking the position that if the different acid gases affect health through the same health endpoint, they can be assumed to interact additively. However, this fundamental assumption is not correct. At least one of the acid gases emitted by boilers, HCN, is a known neurotoxin. Its health effects therefore must not be considered additive with the health effects of other acid gases for which the health endpoint is different. Additionally, although Table VI-1 shows the effects for the target organs and pathways studied, there are other pathways of exposure affecting other target organs, and the combined effects are not additive just as the effects of HCN are not additive with HCl. For these reasons, the Agency should not assume an additive effects among these HAP.

Comment Excerpt Number: 66

Comment: As acknowledged by the Agency, 75 Fed. Reg. 32,032, industrial and commercial boilers are often located at sites with significant additional sources of HAPs and other pollutants. These pollutants can have synergistic effects with the HAPs emitted by the ICIBPH. For example among the pollutants that may be emitted by other emissions units onsite is particulate matter (PM), including PM in the respirable size range, PM10 (PM that are less than or equal to 10 micrometers [?m] in aerodynamic diameter). Health effects associated with PM are stronger for fine (PM2.5) and ultrafine particles (PM0.1) because they can penetrate deeper into the airways of the respiratory tract and can reach the alveoli in which 50% are retained in the lung parenchyma. Under atmospheric conditions volatile HAPs that are emitted by boilers can condense onto the surface of these PM, allowing the HAPs to travel along with the particles. Such particles can serve as “carriers” to bring the adhered HAPS deep within the lung, where the HAPS can interact with the respiratory system directly or be leached off of the particle surface and become available systemically. Other HAPS and criteria pollutants may also be present on PM, including transition metals, ions (sulfate, nitrate), organic compound, quinoid stable radicals of carbonaceous material, minerals, reactive gases, and materials of biologic origin. [Footnote: See, e.g., U.S. EPA, “Review of the National Ambient Air Quality Standards for Particulate Matter: Policy Assessment of Scientific and Technical Information. OAQPS Staff Paper” (2006). EPA-452/R05-005a., available at: http://www.epa.gov/ttnnaaqs/standards/pm/data/pmstaffpaper_20051221.pdf (discussing these effects).]

PM are just one of the additional pollutants that will be emitted from boilers; the fact that boilers can be located among a wide variety of industrial facilities makes predicting and assessing all possible mixtures of HCl and other emitted air pollutants difficult, if not impossible. Because the statute requires standard setting with an “ample margin of safety” when §112(d)(4) is invoked, as discussed above, these synergies make this kind of standard setting practicably impossible to do lawfully for this industrial category.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: Section 112(d)(4)’s Requirement to Set Any Health-Based Standards With “An Ample Margin of Safety” Requires Evaluation of Health Effects Beyond the Fenceline. Environmental Justice Concerns Mitigate Against Anything Other than MACT-based Standards for this Reason.

EPA also requests comment on whether HAP emissions from neighboring facilities must be evaluated in setting §112(d)(4) standards, and, if so, what the geographic scope of such consideration should be. 75 Fed. Reg. 32,032. EPA properly notes that consideration of emissions from nearby facilities is a far more difficult task to undertake in national standard setting than consideration of facility-wide emissions, since it requires information on all potential HAP emissions near all of the locations with the almost 15,500 boilers affected by the rule. The Agency asks, however, whether such standards could be based on “ ‘average’ or ‘high- end’ ambient levels of respiratory irritants seen in recent monitoring data or modeled estimates, since site-specific data might not be available on all respiratory irritants.” 75 Fed. Reg. 32,032. EPA further solicits comment on whether or not it can, and how it should “appropriately “simulate all reasonable facility/exposure situations (e.g., using worst-case facility emissions coupled with worst-case population proximity, average emissions and population, or 90th percentile emissions and population).” Id.

This question by the Agency in fact illustrates why MACT standard setting is and should be the default requirement in the 1990 Clean Air Act, rather than “health-based” standard-setting under section 112(d)(4). The fact that industrial sources of air toxics are often located in areas with other sources of HAPs, including point sources, area sources, and mobile sources, is a major (although not the only) reason that the former, exclusively health-based scheme for standard setting, was so unworkable. Not only are the physical interrelationships between the HAPs synergistic, making the health effects very difficult to predict, but each situation will involve HAPs with different characteristics with respect to spatial distributions, and health endpoints. Defining the geographic scope will not be possible on a nationwide basis for this reason. At the very least, a “high end” ambient level of respiratory irritants as seen in central site monitors or as modeled will have to be used in order to even begin to satisfy the Act’s requirement of an “ample margin of safety.”

Comment: EPA notes that it “considered that setting conventional MACT standards for HCl as well as PM (as a surrogate for metals including manganese) would result in significant reductions in emissions of other pollutants, most notably SO2, non-condensable PM, and other non-HAP acid gases (e.g., hydrogen bromide) and would likely also result in additional reductions in emissions of mercury and other HAP metals (e.g., selenium). The additional reductions of SO2 alone attributable to the proposed MACT standard for HCl are estimated to be 340,000 tons per year in the third year following promulgation of the proposed HCl standard. These are substantial reductions with substantial public health benefits. Although MACT standards may directly address only HAPs, not criteria pollutants, Congress did recognize, in the legislative history to section 112(d)(4), that MACT standards would have the collateral benefit of controlling criteria pollutants as well and viewed this as an important benefit of the air toxics program.” 75 Fed. Reg. 32,032. EPA asserts that even where there is an “established health threshold” for a HAP, the Agency “may consider such benefits as a factor in determining whether to exercise its discretion under section 112(d)(4).” Id.

As a threshold matter, as commenters describe above, there is no “established health threshold” for HCl or for any of the acid gases emitted by ICIBPH, such that a §112(d)(4) standard could be set with an “ample margin of safety.” But even if there were, the Agency would be required to consider – indeed to compare -- the environmental and other impacts and benefits of a MACT standard and a section 112(d)(4) alternative. EPA knows this – the Agency points out, 75 Fed.

Reg. at 32,031, that “employing a §112(d)(4) standard rather than a conventional MACT standard ‘shall not result in adverse environmental effect which would otherwise be reduced or eliminated.’ ” Id. (emphasis added) (quoting S. Rep. No. 228, 101st Cong., 1st Sess. (1989) at 171). It is impossible to make this assessment without evaluating the collateral benefits of a MACT standard. And , as described in the recently finalized cement kiln MACT rule, [Footnote: Available at http://www.epa.gov/ttn/oarpg/t1/fr notices/portland cement fr 080910.pdf.] setting technology-based standards for HCl will result in significant reductions in the emissions of other pollutants, including SO2, mercury, and PM. These reductions will provide enormous health and environmental benefits, that would not be experienced if section 112(d)(4) standards had been finalized.

Comment Excerpt Number: 129

Comment: EPA asserts in the proposed rule that its decision not to propose HBELs “is not contrary to EPA’s prior decisions where we found it appropriate to exercise the discretion to invoke the authority in section 112(d)(4) for HCl, since the circumstances in this case differ from previous considerations.” Draft at 140. In contrast to “other source categories for which EPA has exercised its authority under section 112(d)(4),” EPA explains that boilers and process heaters are more likely to be co-located with other HAP sources and are often located in heavily populated urban areas where many other HAP sources exist. Id. at 140-141. The Agency concludes that, “These factors make an analysis of the health impact of emissions from these sources on the exposed population significantly more complex than for many other source categories, and therefore make it more difficult to establish an ample margin of safety.” Id. at 141.

These assertions are astonishing in that they fail to reflect the fact that the industrial boiler source category is one of the few categories where EPA has previously “found it appropriate to exercise the discretion to invoke the authority in section 112(d)(4).” As a result, EPA has already drawn conclusions as to how to deal with possible co-location with other HAP sources and how to appropriately consider HAP emissions from other nearby sources. These are not issues of first impression generally or in the specific context of industrial boilers and process heaters. The questions have been asked and answered in the context of notice and comment rulemaking for the industrial boiler and process heater source category.

Thus, EPA is mistaken in asserting that its decision not to propose HBELs is “not contrary to EPA’s prior decisions.” The decision not to propose HBELs is flatly inconsistent with EPA’s prior determination that HBELs are appropriate and justified for the industrial boiler and process heater source category.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 130

Comment: The co-benefits of collateral non-HAP emissions reductions cannot be used to justify a decision not to adopt HBELs.

EPA explains in the proposal that "it considered the fact that setting conventional MACT standards for HCl as well as PM (as a surrogate for metals including manganese) would result in significant reductions in emissions of other pollutants, most notably SO2, non-condensable PM, and other non-HAP acid gases (e.g., hydrogen bromide) and would likely also result in additional reductions in emissions of mercury and other HAP metals (e.g., selenium)." Draft at 139. The Agency notes in particular that its belief that the rule will result in the reduction of up to 340,000 tons per year of SO2, which it characterizes as "substantial reductions with substantial health benefits." Id. EPA asserts that Congress acknowledged the possibility that MACT standards would result in collateral non-HAP emissions reductions and, therefore, that "the Agency may consider such benefits as a factor in determining whether to exercise its discretion under section 112(d)(4)." Id. at 140.

EPA is mistaken. Consideration of non-HAP collateral emissions reductions is impermissible in setting MACT standards. Section 112(d)(2) provides an express list of factors that EPA may consider in setting § 112(d) standards – including "the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements." This list does not allow consideration of non-HAP air quality benefits, such as the co-benefits of reducing PM2.5 emissions. This restriction is an unambiguous command that EPA should not consider non-HAP air quality benefits in setting standards under § 112(d).

More fundamentally, the CAA clearly distinguishes regulation of HAPs from criteria pollutants. Section 112 "prohibits the addition of any criteria pollutant to 'the list' of HAPs, with a single exception for certain precursor pollutants not relevant to this case. This prohibition extends of necessity not only to rules that literally list a criteria pollutant as a HAP but also to any rule that in effect treats a criteria pollutant as a HAP." National Lime Ass'n v. U.S. EPA, 233 F.3d 625, 638 (D.C. Cir. 2000).

By basing its rejection of the health-based approach for Boiler MACT on the co-benefits of criteria pollutant reduction, EPA is "in effect" unlawfully treating a criteria pollutant as a HAP. EPA's action here is not the simple use of a criteria pollutant as a surrogate for a HAP, which courts have upheld as long as EPA proves the scientific underpinning of the surrogate relationship. Id. Rather, EPA argues directly that it is the reduction in criteria pollutant emissions that causes it to reject the health-based approach. This EPA cannot do. Moreover, criteria pollutants from boilers are strictly regulated elsewhere under the Clean Air Act through New Source Performance Standards and other provisions of the Act.

EPA's sole support for its "collateral benefits" theory is legislative history -- the Senate Report that accompanied Senate Bill 1630 in 1989. But the D.C. Circuit rejected precisely the same argument in National Lime. In that case, EPA supported its argument regarding particulate matter as a surrogate for HAP metals by referring to the same Senate Report discussed above. The court rejected EPA's argument, noting that the Senate Report referred to an earlier version of the statute that was ultimately not enacted, and hence was irrelevant:

The final statute, by contrast, unqualifiedly prohibits listing a criteria pollutant as a HAP, that is, regardless of the reason. Because the comment in the Senate Report regarding PM and metals was made before the blanket prohibition upon regulating PM as a HAP was added to the statute, the report is irrelevant to our construction of 7412(b)(2) as enacted.
National Lime at 638. Similarly here, EPA cannot use the language of a Senate Report that did not reflect the language of the statute as enacted to support its co-benefits theory and rejection of the health-based approach.

Moreover, even if it were relevant, the language in the Senate Report cited by EPA appears to address only area-source GACT standards under Section 112(d)(5), and therefore is not relevant to interpretation of MACT standards under Section 112(d)(2) or the health- based alternative under Section 112(d)(4). And, in the final analysis, "it is the statute, and not the Committee Report, which is the authoritative expression of the law." City of Chicago v. Env. Defense Fund, 511 U.S. 328, 337 (1994). Here, the statute clearly provides that MACT standards may address only HAPs, not criteria pollutants. See National Lime Ass'n at 638.

Comment: Consideration of non-HAP air quality benefits under § 112(d)(4) would be unreasonable. National Ambient Air Quality Standards ("NAAQS") are in place for all relevant pollutants, including ozone, SO2, and PM. A MACT standard is a very imprecise tool for helping to attain and maintain such NAAQS because it imposes across-the-board requirements in circumstances where tailored solutions are needed. Each area has its own unique mix of sources and it own particular needs in terms of what reductions are needed and where such reductions should be achieved. SIP-based air quality programs provide the needed flexibility to design a program that effectively addresses local air quality needs. MACT standards are an unreasonably blunt instrument for dealing with non-HAP air quality issues.

Comment: Emissions of SO_2 from unit burning biomass are very low when compared to other fuels. The AP-42 emission factor for wood combustion is 0.025 lb/mmBTU and AF&PA's experience with biomass units is that SO_2 emissions are routinely much lower than this emission factor. NCASI also has completed research (NCASI Technical Bulletin 640, Sulfur Capture in Combination Bark Boilers, and Special Report 09-02, Sulfur Capture in Combination Bark Boilers – An Update) that demonstrates that even when sulfur containing fuels are burned with biomass, a significant portion of sulfur is captured by the alkaline wood ash. These 2 documents are available to NCASI members and can be made available to EPA staff upon request. Thus, even if EPA could consider co-benefits of non-HAP reductions in developing standards under § 112, the nominal co-benefits of reducing SO_2 emissions from biomass units would not outweigh the other advantages of establishing a health- based emissions limitation for HCl.

Comment: As noted, the language of CAA Section 112(d)(f) does not express any intent that emissions from other types of sources at a facility or background concentrations should be considered in a cumulative fashion with emissions from permitted source. Evaluation of the acid gas impacts from all regulated boilers at a facility will, in most cases, address virtually all of the irritant gas hazard. With the possible exception of some types of chemical production and metallurgical facilities, nearly all of the industrial emissions of HCl (and other acid gases) at industrial facilities are associated with boilers. As such, computing an acid gas TOSHI associated with boiler emissions only under CAA 112(d)(4) represents the acid gas risk for the entire facility. Once acid gases are emitted from a stack, they have a short atmospheric half-life due to high solubility and reactivity, and as such, concentrations decrease rapidly with distance from a source. Thus, it would be a very unusual circumstance if impacts from multiple facilities would overlap in a cumulative layer cake fashion. This is confirmed by ambient measurement studies in source-rich urban areas, which have shown that HCl concentrations are very low, typically less than 5% of the 20 µg/m3 Reference Concentration (RfC). In coastal areas, most of the airborne HCl is attributable to the contribution of air-sea interaction. Natural coastal deposition of HCl is also reflected in data from EPA's National Acid Deposition Network, which indicates that there is no spatial correlation between deposition and major combustion sources.

Comment: Among the reasons cited by EPA for not proposing the HBEL for HCl in the 2010 Boiler MACT rule is the belief that impacts from other sources at the same facility or nearby facilities may need to be considered in evaluating risk. As noted above, the language of CAA Section 112(d)(4) indicates that only the potential threshold health effects from the MACT source should be considered. Furthermore combined risk sources from various MACT categories should be considered under the residual risk program, after MACT standards have been promulgated and implemented. However, even if an HBEL analysis were to consider these cumulative exposures, the effect would be minimal because the evidence indicates that the potential incremental risk added as a result of overlapping plumes is very small.

The chief acid gas HAPs emitted from most industrial boilers are chiefly HCl (since most elemental chlorine in fuel is converted to HCl during combustion) and HF. A review of TRI 2008 data (excluding EGUs, chemical plants, and metal mining) indicates that 77.3% of acid HAP gas emissions are HCl, 22.4 % are HF and only 0.3% are HCN. As noted, the threshold effects of acid gases are dissimilar to other HAPs and, therefore, these can be considered separately from other HAPs using EPA's TOSHI concept. At most types of industrial facilities that have substantial emissions of acid gases, solid fuel boilers subject to the boiler MACT (or other MACT such as the Hazardous Waste Combustor MACT) are the only significant source of these emissions. Because it is unlikely that there would be a substantial contribution of acid gas HAP emissions that are not regulated under the boiler MACT at most facilities, it should not generally be necessary to consider non boiler MACT sources in establishing HBELs.

Another consideration potentially affecting HBEL development is whether boiler MACT source impacts from nearby facilities overlap. Even if this were applicable under CAA 112(d)(4), dispersion modeling shows that maximum impact short-term and annual average concentrations of non-reactive pollutants associated with boiler emissions generally occur within 1 km and fall off rapidly with distance. This limits the range at which appreciable concentrations of these gases are transported. Because acid gases are highly soluble, react with ammonia the ambient air, and are rapidly deposited through wet and dry deposition, the range of ground-level concentrations is much more limited than for non-reactive pollutants. Therefore, unless there are boilers at an immediately adjacent facility, it is highly unlikely that impacts would overlap to the extent that it would materially affect the HBEL.

There is no evidence that background concentrations of HCl are at appreciable levels from a public health perspective. A limited number of ambient measurement studies have shown that ambient concentrations, even in highly urbanized areas, are very low. A long-term measurement study of ambient acid gas concentrations in New York City (Bari et al 2003) indicates an average of about 0.5 µg/m3, which is only 2.5% of the chronic RfC (Reference Concentration). Thus,

there is little basis for adjusting the HBEL to adjust for background concentrations of acid HAP gases.
A study of HCl emissions and impacts from utility boilers (Harkov 1999) concludes that, even in the vicinity of major sources of HCl, ambient concentrations are very low. This report states: "In the atmosphere, HCl is fairly short-lived…since it is very soluble and reacts readily with ammonia (NH3) or alkaline cations such as Ca or K to form chloride salts. Therefore, even though the mass of HCl emitted may be substantial, the actual impacts of these emissions may not be significant. For example, data from the National Atmospheric Deposition Program (NADP 1998) National Trends Network deposition monitoring network over the years indicates that chloride ion deposition is strongly influenced by sea salts, rather than simply point sources of HCl emissions… EPA did not identify exceedances of any HCl health-based standards in the health risk studies reported in the Utility HAP Report (EPA 1998a)."
The conclusion is that evaluation of non-boiler MACT, multiple facility and background do not need to be considered in establishing HBELs for acid HAP gases.
Another assertion in the proposed Boiler MACT rule is that control of HCl emissions from solid fuel boilers will reduce acidic deposition. A map of chloride deposition in 1997 (from Harkov, 1999) illustrates that there is no correlation between chloride deposition and distance from coal fired power plants in the Ohio Valley or industrial areas in the Midwest but is instead is related to the influence of sea salt, especially in the Pacific Northwest, New England and Southern Atlantic and Gulf coasts. Thus, there is no indication that HCl deposition from major point source emissions contribute materially to chloride deposition or acidification. [See submittal for map of chloride deposition.]

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Melvin E. Keener
Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)
Document Control Number: EPA-HQ-OAR-2002-0058-2824.1
Comment Excerpt Number: 17

Comment: EPA should only consider the affected source and not include all sources at the facility or surrounding facilities.

CRWI believes that Congress expected EPA to consider the effect of co-located facilities during the § 112(f) residual risk program so that, by the time EPA has promulgated residual risk standards for all source categories, risks from co-located sources will be adequately addressed. As'indicated by Senator Durenberger's comments during the debate of the Clean Air Act Amendments of 1990, EPA should consider residual risk in the context of different HAP source. Categories that might be co-located at the same site. See Brick MACT proposal, 67 FR 47894, 47905, fn. 5 (July 22, 2002) citing Senate Debate on Conference Report (October 27, 1990) reprinted in "A Legislative History of the Clean Air Act Amendments of 1990," Comm. Print S. Rrt. 103-38 (1993) ("Legis. Hist.") at 868.

Under § 112(d), however, the targets of regulation are new or existing sources of hazardous air pollutants within the specified source category (or subcategories) under consideration — not all sources at the site. EPA sets these standards by considering the emission levels achieved by the best performers in their respective category or subcategory. CAA § 112(d)(3).

Congress carried this concept into § 112(d)(4) as well. The legislative history explains that the focus of the Agency's authority under section 112(d)(4) is preventing risks from the sources themselves. As the Committee on Environment and Public Works explained, where some sources do emit more than the threshold amount, the Administrator is authorized by section 112(d)(4) to use the no observable effects level of NOEL (again with an ample margin of safety) as the emission limitation in lieu of more stringent "best technology" requirements. Following this scenario, only those sources in the category which present a risk to public health (those emitting in amounts greater than the threshold) would be required to install controls, even though the general policy is "maximum achievable technology" everywhere.

S. Rep. No 228, 101st Cong. Sess. 175-176 (1989) (emphasis supplied).

In addition, there is no prior EPA precedent for considering co-located facilities from a different source category during the same § 112 rulemaking.' In the Benzene NESHAP, where EPA noted that it should consider "effects due to co-location of facilities" id. at 54 FR 38045, EPA was only considering sources from the same category. HOwever, in that rule "co-location" was not all sources at the site. Instead it was all sources within the source category. As explained in a section of the preamble labeled "Application of Policy to Benzene Source Categories" EPA explained that it derived the regulatory level on "model plants" to represent the sources being regulated. For Benzene Storage. Vessels, EPA said, "Where two or more of the model plants used for the analysis might occur at one site (e.g., both a producer and a consumer of benzene), the risks were calculated from their total emissions." Id. at 38050-01. Consequently, EPA examined the effects of co-location only from the "model plants" EPA was evaluating — and not from emissions sources outside the source category it was evaluating.

In summary, consideration of sources outside the source category is antithetical to the concept of MACT standards for individual source categories. CRWI suggests that EPA's limit the §112(d)(4) standard to only those sources within the source category. Thus, a decision to limit the provision's focus_to each unit impacted is supported by Congressional intent and, prior precedent.

Comment: SO2 control is, overestimated.

EPA should not rely on the additional SO2 reductions that will be achieved by HCI control as a public health or environmental benefit to prevent them from establishing a health-based standard. While the Senate mentioned in its report that EPA may consider the benefits that MACT standards might have on nohHAP pollutants, CRWI notes that Congress placed the §112(d)(4) authority in the statute, not just its deliberations, thereby expressing a stronger intent for the Agency to consider and implement.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 44

Comment: The statute makes clear that criteria pollutant co-benefits associated with the proposed MACT standards may not be considered in deciding whether to establish §112(d)(4) health based emissions limitations. Also, EPA has failed to explain why the health based emissions limitations it established in the 2004 Industrial Boiler MACT and the justification provided for those limitations should now be reversed. The preamble to the newly proposed rule sets out a number of questions that might be relevant in deciding whether to establish health based emissions limitations, but merely raising questions is not a sufficient basis for reversing prior determinations adopted through notice and comment rulemaking. Thus, EPA's proposal not to set health based emissions limitations runs counter to the law and is based on an inadequate explanation of why the Agency proposes to depart from its prior approach.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 201

Comment: EPA Should Not Consider Impacts From Multiple Sources For HCl.
CIBO feels strongly that EPA should not consider other sources' emissions when considering impacts from a single source's emissions. One of the reasons EPA has given for not proposing the HBCA for HCl in the Proposed Rule is the belief that impacts from other sources at the same facility or even nearby facilities, may need to be considered. This is an incorrect belief, as Section 112(d)(4) indicates that only the potential threshold effects from the MACT source itself be considered. Moreover, residual risk approaches have not extended beyond the single MACT source.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Douglas A. McWilliams

Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 4

Comment: Providing regulatory flexibility by means of HBELs will not cause any harm to human health or the environment. When the first Boiler MACT rule was promulgated in 2004, it included HBELs for HC1 and manganese. Under both of those standards, a site-specific risk assessment was required to prove that emissions from the site were low enough to protect human health, with an ample margin of safety. Actual emissions testing of all affected emission points was required to verify the emission rates used in the risk assessment. All relevant site parameters were to be recorded in the site's Title V operating permit to provide assurance over time that public health would be adequately protected. See 69 Fed. Reg. at 55227-28. Painesville and Orrville have conducted this testing and their permits reflect the parameters that Ohio EPA and U.S. EPA have determined are adequately protective of human health with a margin of safety. EPA's general speculation about co-located HAP sources and urban HAP loadings are not relevant to these municipal utilities and should not be used to arbitrarily deny health-based relief already approved on a site-specific basis.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 7

Comment: The proposed Rule attempts to justify its adoption of technology-based standards over HBELs by citing the co-benefits of collateral non-HAP emission reduction. Specifically, it explains that "it considered the fact that setting conventional MACT standards for HC1 as well as PM (as a surrogate for metals including manganese) would result in significant reductions in emissions of other pollutants, most notably SO2, non-condensable PM, and other non-HAP acid gases (e.g., hydrogen bromide) and would likely also result in additional reductions in emissions of mercury and other HAP metals (e.g., selenium)." 75 Fed. Reg. at 32032. The Agency notes in particular its belief that the rule will result in the reduction of up to 340,000 tons per year of SO2, which it characterizes as "substantial reductions with substantial health benefits." Id. EPA asserts that Congress acknowledged the possibility that MACT standards would result in collateral non-HAP emissions reductions and, therefore, that "the Agency may consider such benefits as a factor in determining whether to exercise its discretion under section 112(d)(4)." Id. EPA is mistaken. Consideration of non-HAP collateral emissions reductions is impermissible in setting MACT standards. Section 112(d)(2) provides an express list of factors that EPA may consider in setting section 112(d) standards. That list includes "the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements." (Emphasis added.) It does not include consideration of non-HAP air quality benefits, such as the co-benefits EPA cites above. This restriction is an unambiguous command that EPA not consider non-HAP air quality benefits in setting standards under section 112(d).

Standards (,NAAQS") are in place for all relevant pollutants, including ozone, SO2, and PM. A MAC f standard is a very imprecise tool for helping to attain and maintain such NAAQS because it imposes across-the-board national requirements in circumstances where tailored solutions are needed. itch area has its own unique mix of sources and its own particular needs in terms of what reductions are required and where such reductions should be achieved. SIP-based air quality programs provide the flexibility Congress intended to design a program that effectively addresses local air quality needs. MACT standards are an unreasonably blunt instrument that was neither designed nor intended to deal with non-HAP air quality issues.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Susan J. Miller
Commenter Affiliation: Brick Industry Association
Document Control Number: EPA-HQ-OAR-2002-0058-2716.1
Comment Excerpt Number: 8

Comment: BIA is distressed by EPA's growing and illegal dependence on non-HAP benefits to justify a HAP regulation. Congress clearly developed separate sections of the CAA to deal with different pollutants, based on the specific impacts of those pollutants. For example, only HAPs have anything like a "floor" that must be established before a cost and other impacts based final level is established. While we can commend EPA's attempts to provide overall strategy for air quality for an industry, these "good intentions" cannot be used to push through environmental limitations that violate the requirements of the CAA.

For example, EPA has repeatedly argued that it cannot consider costs in the MACT floor. However, EPA then turns around and uses monetized benefits of non-HAP emission reductions as a justification or benefit of their decisions. If costs do not belong in the floor, neither do negative costs (i.e., benefits).

Response: preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Susan J. Miller
Commenter Affiliation: Brick Industry Association
Document Control Number: EPA-HQ-OAR-2002-0058-2716.1
Comment Excerpt Number: 9

Comment: In establishing the emission level that is considered MACT, the CAA clearly and in plain language instructs EPA to NOT consider other air quality benefits, only non-air quality benefits [Section 112(d)(2), emphasis added]:

Emission standards promulgated under this subsection and applicable to new or existing sources of hazardous air pollutants shall require the maximum degree of reduction in emissions of the hazardous air pollutants subject to this sections...where the Administrator, taking into consideration the costs of achieving such emission reduction, and any non air-quality health and environmental impacts and energy requirements, determines is achievable....

This clearly demonstrates that EPA cannot consider other air quality benefits when justifying a MACT, nor can they be considered when identifying the MACT floor. Clearly, Congress recognized that there were other sections of the CAA that could, and should, be used to regulate non-HAP air contaminants. These other programs have totally separate approaches for setting the standards and for considering impacts.

Response: preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 9

Comment: Even taking EPA's concerns regarding co-located sources and proximity to other significant HAP sources in heavily populated urban areas at face value, they do not apply to small municipal utilities. Rather, municipal utilities operate boilers and generators as their exclusive HAP source and do not operate co-located HAP sources within their fence line. Also, AMP members are located in small towns and cities, not in heavily populated urban areas where other HAP sources are common. The Agency concludes that "[t]hese factors make an analysis of the health impact of emissions from these sources on the exposed population significantly more complex than for many other source categories, and therefore make it more difficult to establish an ample margin of safety." 75 Fed. Reg. at 32032. To the contrary, these factors support using an HBEL for a small municipal utilities subcategory.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 11

Comment: That is particularly true with respect to HBELs since municipal utilities do not evoke the two key reservations cited by EPA in the Proposed Rule: the risk of co-located HAP sources and proximity to urban HAP generation. Unlike certain other sources, the only HAP source at small municipal utilities are the boilers that will be subject to regulation by this rule. Also, municipal utilities are located in town centers where zoning precludes a concentration of sources emitting pollutants that may contribute to a synergistic effect in the environment. By their very nature, municipal utilities are located in small towns - far from urban centers where concentration of HAP emissions is a potential concern. Given this unique profile, municipal utilities do not present the obstacles to HBELs that were the subject of EPA's request for comment in the

Proposed Rule preamble. Establishing a subcategory for small municipal utilities thus presents an appropriate and defensible way to narrowly apply HBELs even if EPA determines they are not viable on a broader scale.

Response: See preamble for response to final decision on Health Based Compliance Alternative. See response to comment EPA-HQ-OAR-2002-0058-2795.1, excerpt 1 for additional subcategory for small municipal utilities or subcategorizing according to sector.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 70

Comment: EPA requests comment on whether to consider the affected sources (boilers) by themselves or whether to consider all HAP emissions at the facility when developing a 112(d)(4) standard. Dow comments that EPA's rule should include all sources of the same HAP when requiring an owner/operator to conduct dispersion modeling studies to demonstrate compliance with a HBCA limit. In other words, the owner/operator should include all sources of HCl, Cl2, HF, and HCN at the major source when making a modeling demonstration under section 112(d)(4). This type of approach will ensure that the off-site impact of these emissions is less than thresholds of concern. However, EPA should not require an evaluation of all other HAPs at the site though since they are regulated under many different source categories and they will be reviewed in due time in accordance with the residual risk evaluations.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company

Comment Excerpt Number: 71

Comment: EPA requests comment on whether HAP emissions from nearby neighboring facilities should be considered and what the geographic scope of such consideration should be. These decisions should be made on a case-by-case basis. EPA should issue guidance on when and how to aggregate HAP emissions from multiple sites in close proximity with different owners.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 72

Comment: EPA also mentions in the preamble that setting conventional MACT standards for HCl as well as PM (as a surrogate for metals including manganese) would result in significant emission reductions in emissions of other pollutants, most notably SO2, and would likely also result in additional reductions of other criteria air pollutants. EPA believes that this proposed MACT rule will have the collateral benefit of controlling criteria pollutants as well and views this as an important benefit of the air toxics program. EPA's assumptions are incorrect in some cases. By establishing specific emission limits for certain pollutants, such as CO, for coal fired boilers, regulated entities will be required to install CO emission reduction catalyst in some cases. The use of this catalyst will result in an increase in NOx and also will increase CO_2 emissions from these sources. Likewise, for another subcategory, owner/operators will also be required to operate sources that use "Other Process Gas" in an inefficient manner to approach the proposed limit of 1 ppmv CO, thus again increasing NOx and CO_2 emissions from these sources.

Commenter Name: James C. Jackson

Commenter Affiliation: Boise, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2855.1
Comment Excerpt Number: 4

Comment: For Boise, the health-based emissions limitation alternative is a critical tool that would be used to assure adequate protection of human health and the environment while avoiding unnecessary costly wet scrubbers to control acid gases which are emitted at very low levels from our biomass boilers due the inherent low chloride content of our predominant biomass fuels. Avoiding such wet scrubbing controls arguably would have a positive environmental impact due to the fact that substantial resources (e.g., water use, electric energy) are consumed and more indirect greenhouse gases from purchased electricity are emitted by an additional wet scrubbing process. While EPA is legally not allowed to consider sulfur dioxide emission reduction co-benefits in this rulemaking that might occur from wet scrubbing, in Boise's case, such co-benefits would be insignificant due to the fact that there is very little sulfur in the biomass fuels we predominantly burn and thus very low sulfur dioxide emissions.

Document Control Number: EPA-HQ-OAR-2002-0058-2840.1
Comment Excerpt Number: 5

Comment: Multi-source, multi-pollutant and multi-media analyses have not prevented implementation of air quality standards in the past. Given that the proposed standards (without HBELs) will potentially lead to the closure of several manufacturing facilities within the US, EPA should exercise their discretionary authority to provide the regulated industry an option to comply with emission limits or alternative health-based emission limits. HBELs are not only a consistent precedent for establishing National Ambient Air Quality Standards (NAAQS) but also enables industry to focus on reductions that will result in the greatest environmental benefit.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Jerry Osheka
Commenter Affiliation: PPG Industries
Document Control Number: EPA-HQ-OAR-2002-0058-2938.1
Comment Excerpt Number: 11

Comment: In response the request for comments on whether EPA should “consider the affected sources (boilers) by themselves, or whether we should consider all HAP emissions at the facility when developing a 112(d)(4) standard” (FR 32,032), PPG believes that EPA should consider affected sources individually. Few significant sources of HCl exist other than large utility boilers that are part of the industrial boilers and process heaters regulated under this proposed rule. Those utility boilers, in most cases, will be regulated by both the Utility MACT and the Clean Air Transport Rule, providing the EPA with ample opportunity to effect improvements to public health by regulating acid gas emissions from those units. EPA should not disproportionately burden industrial sources with the combined effects of their own emissions plus those of other sources by considering emissions from other affected sources in the area.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: An HCl HBCA should be implemented for biomass boilers
Notwithstanding Georgia-Pacific’s basic position that EPA can and should establish an “across the board” HBCA for HCl, we believe that EPA has the authority under section 112(d)(4) to establish a Risk-Based Standard for HCl specifically for inherently low SO2 emitting biomass boilers. EPA recently decided in the Portland Cement Manufacturing Industry MACT not to establish a risk-based standard for HCl partly on the basis of the secondary benefits associated with controlling SO2 emissions. While GP and EPA may disagree on the legality of considering the secondary benefits of controlling criteria pollutants while establishing a NESHAP; there should be no disagreement that the secondary SO2 control benefits associated burning biomass are very small and the added costs of controls is not justified.
Emissions of SO2 from units burning biomass are very low when compared to other fuels. AP-42 emission factors for wood residual combustion is 0.025 #/mmBTU1 and GP’s experience with our biomass units is that SO2 emissions are routinely much lower then this emission factor. NCASI has also completed research (NCASI Technical Bulletin 640) that demonstrates that even

when sulfur containing fuels are burned with biomass, a significant portion of sulfur is captured by the alkaline wood ash. Therefore since controlling HCl does not result in a concurrent SO2 reduction, SO2 reduction should not be used as a basis for justifying HCL controls.
[Footnote 1: By comparison, the AP-42 emission factor for coal-fired units is about 2 lb/MMBtu.]

Comment: In response to the request for comments on whether EPA should "consider the affected sources (boilers) by themselves, or whether we should consider all HAP emissions at the facility when developing a 112(d)(4) standard" (FR 32,032), IECA believes that EPA should consider affected sources individually. Few significant sources of HCl exist beyond the industrial boilers and process heaters regulated under this proposed rule, other than utility boilers. Those utility boilers will be regulated by both the Utility MACT and the Clean Air Transport Rule, providing the EPA with ample opportunity to effect improvements to public health by regulating acid gas emissions from those units. EPA should not disproportionately burden industrial sources with the combined effects of their own emissions plus those of other sources by considering emissions from other affected sources in the area.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: From a legal standpoint, the statute makes clear that criteria pollutant co-benefits associated with the proposed MACT standards may not be considered in deciding whether to establish Section 112(d)(4) health based emissions limitations. Also, EPA has failed to explain why the health based emissions limitations it established in the 2004 Boiler MACT rule and the justification provided for those limitations should now be reversed. The preamble to the newly proposed rule sets out a number of questions that might be relevant in deciding whether to establish health based emissions limitations, but merely asking questions is not a sufficient basis for reversing prior determinations adopted through notice and comment rulemaking. Thus, EPA's proposal not to set health based emissions limitations runs counter to the law and is based on an inadequate explanation of why the Agency proposes to depart from its prior approach.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Comment: The co-benefits of collateral non-HAP emissions reductions cannot be used to justify a decision to ignore HBELs.

EPA explains in the proposal that "it considered the fact that setting conventional MACT standards for HCl as well as PM (as a surrogate for metals including manganese) would result in significant reductions in emissions of other pollutants, most notably SO2, non-consensable PM, and other non-HAP acid gases (e.g., hydrogen bromide) and would likely also result in additional reductions in emissions of mercury and other HAP metals (e.g., selenium)." 75 Fed. Reg. 32032. The Agency notes in particular that its belief that the rule will result in the reduction of up to 340,000 tons per year of SO2, which it characterizes as "substantial reductions with substantial health benefits." Id. EPA asserts that Congress acknowledged the possibility that MACT standards would result in collateral non-HAP emissions reductions and, therefore, that "the Agency may consider such benefits as a factor in determining whether to exercise its discretion under section 112(d)(4)." Id.

EPA is mistaken. Consideration of non-HAP collateral emissions reductions is impermissible in setting MACT standards. Section 112(d)(2) provides an express list of factors that EPA may consider in setting § 112(d) standards – including "the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements." This list does not allow consideration of non-HAP air quality benefits, such as the co-benefits of reducing PM2.5 emissions. This restriction is an unambiguous command that EPA should not consider non-HAP air quality benefits in setting standards under § 112(d). This prohibition extends of necessity not only to rules that literally list a criteria pollutant as a HAP but also to any rule that in effect treats a criteria pollutant as a HAP. National Lime Ass'n v. U.S. EPA, 233 F.3d 625, 638 (D.C. Cir. 2000).

By basing its rejection of the health-based approach for Boiler MACT on the co-benefits of criteria pollutant reduction, EPA is in effect unlawfully treating a criteria pollutant as a HAP. EPA's action here is not the simple use of a criteria pollutant as a surrogate for a HAP, which courts have upheld as long as EPA proves the scientific underpinning of the surrogate relationship. Id. Rather, EPA argues directly that it is the reduction in criteria pollutant emissions that causes it to reject the health-based approach. This EPA cannot do. [Footnote: Moreover, criteria pollutants from boilers are strictly regulated elsewhere under the Clean Air Act through New Source Performance Standards and other provisions of the Act.]

EPA's sole support for its "collateral benefits" theory is legislative history -- the Senate Report that accompanied Senate Bill 1630 in 1989. But the D.C. Circuit rejected precisely the same argument in National Lime. In that case, EPA supported its argument regarding particulate matter as a surrogate for HAP metals by referring to the same Senate Report discussed above. The court rejected EPA's argument, noting that the Senate Report referred to an earlier version of the statute that was ultimately not enacted, and hence was irrelevant:

The final statute, by contrast, unqualifiedly prohibits listing a criteria pollutant as a HAP, that is, regardless of the reason. Because the comment in the Senate Report regarding PM and metals was made before the blanket prohibition upon regulating PM as a HAP was added to the statute, the report is irrelevant to our construction of 7412(b)(2) as enacted.

National Lime at 638. Similarly here, EPA cannot use the language of a Senate Report that did not reflect the language of the statute as enacted to support its co-benefits theory and rejection of the health-based approach.

Moreover, even if it were relevant, the language in the Senate Report cited by EPA appears to address only area-source GACT standards under Section 112(d)(5), and therefore is not relevant to interpretation of MACT standards under Section 112(d)(2) or the health based alternative under Section 112(d)(4). And, in the final analysis, "it is the statute, and not the Committee Report, which is the authoritative expression of the law." City of Chicago v. Env. Defense Fund, 511 U.S. 328, 337 (1994). Here, the statute clearly provides that MACT standards may address only HAPs, not criteria pollutants. See National Lime Ass'n at 638.

But, even if it were not unambiguously prohibited, consideration of non-HAP air quality benefits under 112(d)(4) would be unreasonable. National Ambient Air Quality Standards ("NAAQS") are in place for all relevant pollutants, including ozone, SO2 , and PM. A MACT standard is a very imprecise tool for helping to attain and maintain such NAAQS because it imposes across-the-board requirements in circumstances where tailored solutions are needed. Each area has its own unique mix of sources and it own particular needs in terms of what reductions are needed and where such reductions should be achieved. SIP-based air quality programs provide the needed flexibility to design a program that effectively addresses local air quality needs. MACT standards are an unreasonably blunt instrument for dealing with non-HAP air quality issues.

Comment Excerpt Number: 108

Comment: EPA Cannot Use section 112 As A Backdoor To Regulate Criteria Pollutants. EPA is proposing in this rule to set a MACT standard for HCl, and not a section 112(d)(4) health-based standard, in part because the MACT standard, in addition to the direct effect of reducing HCl, would also result in the reduction of non-HAP criteria pollutants emitted by boilers. EPA is using section 112 to further regulate and reduce emissions of criteria pollutants. This is impermissible for the reasons set forth below.

Under section 112(d)(4) EPA has the discretion to establish a health-based standard as an alternative to a technology driven standard for a HAP with a health threshold.[For "pollutants for which a health threshold has been established, the Administrator may consider such threshold level, with an ample margin of safety, when establishing emission standards under this subsection ." 42 U.S.C. section 7212(d)(4).] EPA chose not to do so here because, among other reasons, it determined that "MACT standards for HCl ... would result in significant reductions in emissions of other pollutants."[75 Fed. Reg. at 32139.] EPA's attempt to gain greater reductions in emissions of criteria pollutants through section 112 HAP limits is not allowed and this attempt is particularly unacceptable when EPA proposes to require the over-regulation of a threshold HAP to achieve those reductions.

The CAA clearly distinguishes regulation of HAPs from criteria pollutants. Section 112

"prohibits the addition of any criteria pollutant to "the list" of HAPs, with a single exception for certain precursor pollutants not relevant to this case. This prohibition extends of necessity not only to rules that literally list a criteria pollutant as a HAP but also to any rule that in effect treats a criteria pollutant as a HAP."[National Lime Ass"n v. U.S EPA, 233 F.3d 625, 638 (D.C. Cir. 2000).]
By basing its rejection of the health-based approach for HCl on the co-benefits of reducing emissions from a criteria pollutant, EPA is "in effect" unlawfully treating a criteria pollutant as a HAP. EPA's action here is not the simple use of a criteria pollutant as a surrogate for a HAP, which courts have upheld as long as EPA proves the scientific underpinning of the surrogate relationship.146 Rather, EPA argues directly that it is the reduction in criteria pollutant emissions that causes it to reject the health-based approach. This EPA cannot do.[Moreover, criteria pollutants from boilers are strictly regulated elsewhere under the CAA through NSPS and other provisions of the Act.]

EPA's sole support for its "collateral benefits" theory is legislative history -- the Senate Report that accompanied Senate Bill 1630 in 1989. But the D.C. Circuit rejected reliance on this Report in National Lime. In that case, EPA supported its use of PM, a criteria pollutant, as a surrogate for HAP metals by referring to the Senate Report discussed above. The court rejected EPA's argument, noting that the Senate Report referred to an earlier version of the statute that was ultimately not enacted, and hence was irrelevant:

The final statute, by contrast, unqualifiedly prohibits listing a criteria pollutant as a HAP, that is, regardless of the reason. Because the comment in the Senate Report regarding PM and metals was made before the blanket prohibition upon regulating PM as a HAP was added to the statute, the report is irrelevant to our construction of 7412(b)(2) as enacted.[National Lime at 638.]

Similarly here, EPA cannot use the language of a Senate Report that did not reflect the language of the statute as enacted to support its co-benefits theory and rejection of the health-based approach.

Document Control Number: EPA-HQ-OAR-2002-0058-2385
Comment Excerpt Number: 3

Comment: The 2004 version of the Industrial Boiler MACT included health based emissions limitations for HCl and manganese. Based on stack test results, a total of seven boilers located at three of our facilities were able to employ the 2004 rule’s HBCA allowance to demonstrate compliance for Particulate Matter and HCl. Under the new MACT proposal, those facilities are now required to install pollution control equipment at an estimated collective capital cost $42.3 million and additional annual operating costs of $4.1 million.

The health-based emissions limitations established in the 2004 MACT rule were developed under rigorous standards that protected public health with an ample margin of safety. EPA can and should set health-based standards that are clearly and unequivocally allowed by the Clean Air Act.

Commenter Name: Theresa Pugh
Commenter Affiliation: American Public Power Association
Document Control Number: EPA-HQ-OAR-2002-0058-2714.1
Comment Excerpt Number: 4

Comment: EPA's decision to eliminate health-based emissions limits is particularly troubling given its conclusion that the proposed rule is likely to affect a substantial number of small entities, including small governments operating public power systems. Upon reaching this conclusion, EPA had an affirmative duty under the Small Business Regulatory Enforcement Fairness Act (SBREFA) to consider compliance costs and regulatory alternatives that could ease the burden on small entities. As part of this effort, EPA convened the Small Business Advocacy Panel, which identified health-based compliance alternatives as "the most important step EPA could take to mitigate the serious financial harm the Boiler MACT would otherwise inflict on small entities using solid fuels nationwide . . . ." When EPA adopted a health-based alternative for HCl in 2004, it estimated that affected sources would save $2 billion in compliance costs at no expense to human health or the environment. This could be a low estimate, because one small government municipal utility has received a cost estimate for over $22 million to control HCl emissions; the same HCl emissions that posed no health threat under the 2004 Boiler MACT rule. In fact, EPA approved the health-based compliance alternative for this facility in 2007 recognizing that its stack height and distance to fence line assured protection of human health with an ample margin of safety. Yet EPA provided no explanation for why an HBEL is no longer available to this small government and the many like it and what now justifies wasting billions of dollars in compliance costs on pollutants for which EPA cannot demonstrate an adverse health effect. EPA's decision to eliminate HBELs from the proposed rule without justifying its departure from EPA's 2004 reasoning is arbitrary and capricious.

If unable to comply, APPA members may be forced to abandon the standby and backup capacity, and start-up boilers, at significant detriment to the reliability of the electricity service provided. As such, work practices under 112(h) are needed, or preferably limited use exemptions for boilers operating less than 10% of their annual heat input capacity, to ensure reliable and efficient electricity service.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 2

Comment: As EPA recognized, the proposed Boiler MACT rule will likely have a significant impact on a substantial number of small entities. 75 Fed. Reg. at 32044. Given that EPA has set emissions standards that no existing units can meet, it is likely that every existing unit subject to an emission standard will need to be retrofitted. Even AMP member the City of Painesville, which is listed as one of the top performing sources for HC1 emissions in EPA's database, would need control equipment to ensure that it can meet the proposed HC1 standard of 0.02 lb/mmBtu at all times. We are attaching the original stack test reports and additional stack test reports for Painesville's stoker units (Unit 3 and Unit 4) that should be included in EPA's database (see submittal for stack test reports) and used to recalculate the MACT floor emission rates. These snapshot test runs indicate significant variability in HC1 emissions (0.002 to 0.021 lb/mmBtu) resulting in an upper predicted emission rate in excess of the proposed emission limit for stoker coal boilers. Painesville was the only AMP member in the top performing 12% of the existing sources in EPA's database. Without further relief, all members would thus face control technology costs to address HC1 emissions from sources that have been demonstrated to be below the 2004 Health Based Compliance Alternative for HC1 concentrations at the fence line. For small municipal utilities, the cost of these retrofits is staggering. The City of Orrville and the City of Painesville operate municipal electric plants that provide electricity to the residents and businesses of their respective communities in Ohio. Each independently evaluated the cost of controlling HC1 emissions and determined that the capital cost for an acid gas scrubber to meet the proposed emission limits for a single unit would be $5-16 million. Additional annual operating costs were estimated to be $900,000 to $1.2 million per year. Orrville operates four units and Painesville operates three. Thus, the facility-wide capital cost for HC1 control alone could exceed $40 million with another $3-4 million per year in annual operating costs. This represents $33,000 per customer in capital costs and an additional $3,000 per customer for annual operating costs. These costs pose insurmountable burdens on small municipal electric systems to reduce HC1 emissions that do not pose a health risk.
For many small entities, the capital costs alone will force them to shut down. For AMP member St. Marys, the threat of millions of dollars in additional annual operating costs made continuing operations uneconomical and impractical and they shut down operations in anticipation of the Boiler MACT rule. Others will follow if EPA fails to achieve a better balance between benefit and burden in this rule. [Footnote: Even capital costs of less than $1 million are an impossibility for some small businesses. As Thomas Machamer of Cedar Lane Farms Corporation notes, the $500,000 in control equipment and installation costs necessary to comply with proposed rules represents "nearly half of our yearly sales" and "will put us out of business." See Letter from Thomas Machamer, President, Cedar Lane Farms Corp., to Jim Eddinger, U.S. EPA, re: Rulemakings, HAPs and Public Comments (Dec. 2, 2008)] Implementation of this rule will significantly hinder municipal utilities' ability to provide reliable electrical services to their

communities, peaking capacity to avoid brownouts, and quality work opportunities for local residents. Adopting MACT standards that force small entities to severely curtail or eliminate operations is contrary to the intent of Congress, v?hich has stated that -.MACT is not intended to . . . drive sources to the brink of shutdown." I lousE REP. No. 101-490, Part 1 (1990) at 328. But that is precisely what will happen to small entities under the Proposed Rule unless changes are made.

Adoption of an HBEL for HC1 would significantly reduce the cost burden mandated by the Proposed Rule that would otherwise crush numerous small entities. The Small Business Advocacy Panel, convened by EPA, identified health-based compliance alternatives as "the most important step EPA could take to mitigate the serious financial harm the Boiler MACT would otherwise inflict on small entities using solid fuels nationwide. . . ." SBA REVIEW PANEL, FINAL REPORT at 23 (emphasis added). HBELs would provide regulatory flexibility by allowing small entities to meet emission limitations that are protective of human health and the environment without investing millions of dollars in unnecessary control equipment. Small municipalities, which already struggle to provide services in the face of shrinking revenues, should not be forced to spend millions of dollars badly needed elsewhere on control equipment that will provide no additional health or environmental benefits.

These health-based emissions limitations were rigorous standards that demanded accountability. They were a winner for the Agency and the public because public health would have been protected with an ample margin of safety. At the same time these standards were a winner for affected sources because the standards would not have required expensive control equipment to blindly reduce emissions below levels necessary to assure public safety. It was estimated at the time that these health-based standards would have saved over $2 billion in compliance costs, as compared to the technology-based standards that otherwise would have applied. For small public utilities like Painesville and Orrville, health-based standards could cut compliance costs in half and allow these and other small entities to avoid shutdown or reductions in essential services with no danger to the public health or the environment.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 6

Comment: While EPA has discretion in deciding whether to set HBELs under section 112(d)(4), the Agency cannot be arbitrary and capricious in making such a decision. The proposed HC1 and PM emissions limitations for all types of industrial boilers are exceedingly stringent. Affected sources will have to spend tens of millions of dollars in order to meet the standards, and a significant number of existing units simply will not be able to meet the standards and will be forced to shut down. Shutclovm for small entities in particular is likely given the tremendous costs associated with the control equipment necessary to meet proposed emission limits.

The costs and burdens on affected sources and the degree of control needed to provide adequate health and environmental protection are both key factors that should be considered by the

Agency in deciding whether to adopt HBELs in the Boiler MACT rule. EPA has an affirmative duty to consider the costs imposed on small businesses and government entities pursuant to the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, as amended by the Small Business Regulatory Enforcement Fairness Act, and to consider the costs of alternative regulatory approaches. However, the Agency's discussion of HBELs includes no assessment whatsoever of the costs that might be avoided by adopting HBELs for HC1 or manganese. This failure is significant, as the scrubber technologies needed to meet proposed HC1 limits make up more than half the estimated capital and operating costs small entities like Orrville are expected to incur for Boiler MACT compliance. These costs could well mean the difference between shutting down and continuing as a viable business to small entities. As to potential effects on health or the environment, EPA simply raises implementation questions and asserts a lack of information. Such an approach is facially inadequate in light of the extensive policy, scientific, and technical assessment developed in support of the HBELs in the 2004 Boiler MACT rule standard.

Comment: When the first Industrial Boiler MACT was promulgated in 2004, it included health-based emissions limitations for two HAPs – hydrogen chloride (“HCl”) and manganese. These health-based emissions limitations were rigorous standards that demanded accountability. This presented a win for the Agency and the public because public health would have been protected with an ample margin of safety. At the same time these standards were reasonable for affected sources because the standards would did not blindly require emissions to be reduced far below the levels needed to assure that the public was protected and as a result did not require unnecessary expense for the installation of unnecessary controls. It was estimated at the time that these health based standards would save over $2 billion in compliance costs, as compared to the technology-based standards that otherwise would have applied. Under the current proposed rule and proposed HCl emissions limits, PPG estimates it will cost at least $100 million to install and upgrade required emissions controls on our boilers at our single coal-fired facility. We estimate, if health-based emissions limits are provided, that cost of compliance will drop to approximately $20 million – not an insignificant amount, but certainly a significant cost-reduction. During this fragile economic recovery, imposing unnecessary cost burdens of this magnitude onto industrial firms that are daily exposed to foreign competition, in order to achieve an unspecified health benefit that is merely assumed and not supported by peer-reviewed research, is wholly unreasonable and capricious. PPG urges EPA to establish health-based emissions limits to protect both the public health and the high-quality jobs that American industry provides.

Comment: EPA states that respiratory toxicity effects from HCl exposure are known and understood, and cites a reference concentration (RfC) for HCl that is presumed adequate to protect human health. EPA further states that there is limited data examining the carcinogenicity of HCl. Then EPA contends that while the agency is "aware of no studies explicitly addressing the toxicity of mixtures of HCl with other respiratory irritants," it makes the extraordinary leap of assuming "an additive cumulative effect" of HCl with other HAPs (FR 32,031). IECA contends that such a conclusion, drawn despite the lack of any supporting data, is wholly inappropriate. IECA urges EPA to establish a HBCA process for sources to demonstrate adequate protection of human health as allowed under §112(d)(4) of the Clean Air Act, by considering emissions of HCl, Cl2, HF and HCN from the affected source in comparison against the appropriate RfC. IECA contends that evaluating a source's HCl emissions against the RfC will provide ample protection to public health with a margin of safety.
Unless quantitative, peer-reviewed data showing the additive cumulative effect of acid gases with other HAPs is produced, EPA's assumption that this purported effect does exist imposes an unreasonable cost burden on many small sources with wholly unsupported health benefits in return. One member company determined the cost to install acid gas scrubbers on its industrial boilers at a single site would exceed $200 million. During this fragile economic recovery, imposing cost burdens of this magnitude onto industrial firms that are daily exposed to foreign competition, in order to achieve an unspecified health benefit that is merely assumed and not supported by peer-reviewed research, is wholly unreasonable and capricious. IECA urges EPA to allow HBCA provisions to protect both the public health and the high-quality jobs that American industry provides.

Comment: The EPA should use an approach to set all the standards that are based on what real world boilers actually can achieve. High quality data should be used in making decisions after careful review by EPA. And, facilities should not be forced to install controls where analyses show emissions are safe.

EPA's proposed Boiler MACT can be crafted in a more balanced way that sustains both the environment and good jobs and doesn't hurt our ability to compete against imported products. If EPA were to provide more flexible approaches in the final Boiler MACT rule and appropriately address the diversity of boilers and fuels in use, it could achieve its goal while preventing severe job losses and billions of dollars in unnecessary regulatory costs.

Response: See preamble for response to final decision on Health Based Compliance Alternative. See preamble for rationale for selecting a work practice for these Gas 1 units. Comment: EPA should use its authority in section 112(d)(4) of the Clean Air Act to set health-based emission limits to protect the environment and public health. In order for companies to deploy capital to the right mills, tests for compliance should be done on a facility-by-facility basis. With the many different types of boilers utilized by the industry, one size does not fit all.

Comment: EPA also has the authority in section 112(d)(4) of the Clean Air Act to set health-based emission limits to protect the environment and human health. This would avoid unnecessary controls where emissions of threshold pollutants are low enough to be safe. We're encouraged that EPA invited comment on this, and we believe it should be adopted in the final rule on a facility-by-facility basis. The best way to target investments is where actual problems exist.

Comment: Now, it's probably never a good idea to complain about something without offering a solution.
We suggest the use of a health risk analysis in lieu of the one-size-fits-all regulations that are proposed.
Some years ago California enacted what is called the Air Toxics Hot Spots Program, the AB2588 program, which requires a health risk analysis based on power plant emissions and toxics. This was done in California and a number of years ago. All biomass plants were suggested to the health risk analysis and all passed. We burn clean wood chips. Unfortunately, the category of fuel known as Construction and
Demolition Wastes referred to as C and D, they're looped together.
Our plants take construction waste with clean cutoffs. Our permits prohibit painted or otherwise treated wood in our fuel plant. So demolition waste is generally completely ruled out. We would suggest that in lieu of either the Boiler MACT or the
Area Source Rule for biomass power plants not burning waste but burning clean wood chip fuel, be subjected to a health risk analysis based on measured stack emissions and accepted health risk methodologies.

Comment: Include a Health Based Compliance Alternative. EPA included options in the original standard to allow sources to demonstrate an alternative standard that was protective of health and the environment. EPA has chosen not to do so in the proposed rules. Further, it has set up a nearly impossible standard to meet in the Preamble to the
Boiler MACT Rule, if it were to consider such an alternative. MeadWestvaco believes that EPA has an obligation to ensure that standards it requires are imposed due to a reasonable risk to the health and the environment and not due to a mathematical exercise.

Comment: Facilities that originally met the very conservative health-based compliance option must now install a series of control device costing millions of dollars. Without a health-based compliance alternative, most wood products facilities would either close down or purchase natural gas boilers, which can be obtained at a fraction of the cost of the required control.
The biomass fuel would then be sent to a landfill where it would degrade to methane.

Comment: EPA should allow facilities to demonstrate that emissions of certain pollutants do not pose a public health concern. A practical health oriented standard for threshold pollutants would allow sources to demonstrate their emissions of these compounds pose no adverse risk. The Clean Air Act in §112(d)(4), expressly contemplates the use of such an approach which can be implemented without sacrificing risk reduction benefits. A health threshold standard is critical to the future viability of biomass and other boiler fuels. EPA has indicated to stakeholders that this alternative will not be part of the proposed rule language. EPA should revisit this thinking and make the health threshold standard an integral part of its proposed Rules and allow an opportunity for public comment on this approach.

Comment: Requiring this investment means additional job losses in our industry and in the important manufacturing sector of our economy. At a time when we should be promoting job and economic growth at home, we are handicapping U.S. industry with a new layer of regulations that are unproven to provide any health or environmental benefit.

Two particular components of the Boiler MACT regulation are of particular concern. The first is the lack of any health-based assessment. When the Clean Air Act was first developed, Congress established that lowering emissions further would only be necessary when there are clearly-defined health benefits. Without a health-based assessment, the regulation could require significant investments in actions that would not provide any corresponding benefit.

Comment: The Administrator must evaluate the potential for environmental impacts when considering whether to exercise her discretion under § 112(d)(4). As the legislative history indicates, and EPA correctly notes, "employing a §112(d)(4) standard rather than a conventional MACT standard 'shall not result in adverse environmental effect which would otherwise be reduced or eliminated.' " 75 Fed. Reg. 32,031 (emphasis added) (quoting S. Rep. No. 228, 101st

Cong., 1st Sess. (1989) at 171). It is therefore not only “appropriate to consider potential adverse environmental effects in addition to adverse health effects when setting an emission standard . . . under 112(d)(4),” Id. 32,031(emphasis added), EPA must do so, and must show that any resulting health threshold based standard does not cause adverse environmental effects in excess of those that would result from a MACT standard.

Comment Excerpt Number: 137

Comment: CAA 112(d) enables EPA to establish alternative MACT standards by applying provisions such as the HBEL to avoid unnecessary regulation for HAPs that do not pose a health risk. In 2004, EPA determined that two HAPs commonly emitted from solid fuel industrial boilers, hydrogen chloride (HCl) and manganese (Mn), are threshold pollutants that do not pose a significant health risk at a potentially large proportion of regulated sources. If it can be demonstrated that health benchmarks are met for these HAPs, emission controls for these materials are not deemed to be necessary.

Similar considerations for addressing HCl as a threshold pollutant have been included in 1) National Emission Standards for Hazardous Air Pollutants: Final Standards for Hazardous Air Pollutants for Hazardous Waste Combustors (Phase I Final Replacement Standards and Phase II); Final Rule; 2) National Emission Standards For Hazardous Air Pollutants; Proposed Standards For Hazardous Air Pollutants From Chemical Recovery Combustion Sources At Kraft, Soda, Sulfite, And Stand-Alone Semichemical Pulp Mills; 3) National Emission Standards for Hazardous Air Pollutants From the Portland Cement Manufacturing Industry; and 4) National Emission Standards for Hazardous Air Pollutants: Chlorine and Hydrochloric Acid Emissions From Chlorine Production. In the absence of specific scientific evidence to the contrary, it has historically been EPA’s policy to classify non-carcinogenic effects as threshold effects, as demonstrated in the above rulemakings.
The logic provided by EPA in developing the 2004 HBCA was a direct interpretation of 112(d)(4). In summary:
* Hydrogen chloride is the chief acid gas HAP from solid fuel combustion and emissions are related to chloride and chlorine content in fuel. Hydrogen chloride and chlorine are threshold HAPs with associated similar effects and established Reference Concentrations (RfC), such that the combined inhalation risk of these HAPs can be considered collectively.

* Manganese is a threshold HAP metal, which is a chief risk driver for wood-fired boilers. The 2004 Boiler MACT included emission standards for Total Selected Metals (TSM), of which manganese was a component. The HBCA would exempt manganese from the TSM calculation.

* 112(d)(4) was interpreted to require that all MACT boilers (i.e., from the same MACT source category) at a single facility not significantly contribute to risk. It does not require risk evaluation of other HAPs with different types of health effects or contribution from other sources or background concentrations, as presently suggested in the proposed rule. In 2004, EPA stated the basis for this determination in response to comments that cumulative risks should be evaluated under the HBCA. EPA responded that 112(d)(4) does not indicate that a risk assessment should be undertaken, but simply that the threshold level of a particular HAP should be considered and that it is appropriate to consider cumulative risk under 112(f), which requires the evaluation of residual risk after the implementation of MACT standards. Section 112(f)(1)(c) states that EPA will address "actual health effects with respect to persons living in the vicinity of sources, any available epidemiological or other health studies, risks presented by background concentrations of hazardous air pollutants" in the residual risk assessments.

Rather than this direct interpretation of the CAA 112(d)(4) applied by EPA in 2004, the preamble to the 2010 proposed Boiler MACT repeatedly cites congressional intent, suggesting expanding the consideration of threshold level to other tangential issues such as MACT HAP controls also reducing criteria pollutant and ecological benefits of controls. Although such objectives may appear to be meritorious from an overall environmental protection perspective, there is no indication from the language of 112(d)(4) that other factors besides human health effects of specific threshold HAPs are intended to be considered.

Response: See preamble for response to final decision on Health Based Compliance Alternative.

Commenter Name: Timothy Hunt

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 140

Comment: EPA has a great deal of latitude in exploring other ways to "consider threshold levels with ample margin of safety". Even though the MACT are primarily technology-based standards, the intent of section 112(d)(4) is to allow flexibility for EPA to establish special provisions for threshold HAPs that do not contribute significant health risk. Here we provide a conceptual model of how an HBEL could be incorporated into the Boiler MACT.

Following the approach of the Health Based Compliance Alternative of the 2004 Boiler MACT rule, HBELs could either be established through conservatively-derived look-up tables (Tier 1 HBEL) or a facility could develop a site-specific HBEL based on modeling following EPA guidance (EPA, 2004) (Tier 2 HBEL). A facility would need to certify through fuel analysis or source testing that its boiler emissions meet the corresponding HBEL. Alternatively, limits for HCl and other pollutants that are already established in a facility's air permit could be used in lieu of HBELs.
Toxicity Considerations in Developing HBELs
Because it is acknowledged that some of the HAPs subject to HBELs may have overlapping health effects, rather than considering only individual HAP exposure, the concept of Target

Organ Specific Hazard Index (TOSHI) following U.S. EPA Guidance (EPA 2004) may be appropriate in some instances. The hazard index concept inherently assumes that potential health effects due to simultaneous exposure are additive. [This method was applied in the 2004 Boiler MACT HBCA where the effects of Cl2 and HCl were assumed to be additive by computing HCl toxic equivalent emissions. Although not elaborated in these comments, it is inherently assumed, that this same or similar approach for combining effects of Cl2 and HCl effects is appropriate.]
As noted above, adding the health effects is appropriate for the acute health effects of the primary HAP acid gases from solid fuel industrial boilers, HCl, Cl2.and HF, and adding chronic effects of HCl and Cl2 is also appropriate. For instance, following the TOSHI concept, the development of acute HBELs for acid gases can consider combined emissions of HCl, Cl2and HF, and development of chronic HBELs can consider combined emissions HCl and Cl2 based on toxicity weighted emissions. In this case, an HCl acid gas toxicity-weighted short-term emission rate can be defined as the emission rate of HCl + the emission rate of Cl2 x Threshold of HCl /Threshold of Cl2 + the emission rate of HF x Threshold of HCl /Threshold of HF.
Establishment of separate chronic 112(d)(4) HBEL for HF and HCN is supported since the critical effect/target organ on which the chronic toxicity criteria are based is different for the two acid gases and the mechanism of action is different as well. Because Mn health effects and mechanisms of action can be differentiated from other HAPs, HBELs for Mn should be established independently.
Tier 1 HBELs – Based on Physical Parameters using Look-up Tables
The HBELs could take the form of a limited number of alternative HAP emissions limits that would be based on simple physical parameters related to dispersion. These limits would be set in such a way that there would be no health effects due to inhalation of specified threshold HAPs such as acid gases (primarily hydrogen chloride) and metals such as Mn.
EPA could develop Tier 1 HBELs based on screening-level dispersion modeling that conservatively relates maximum off-site concentrations associated with all Boiler MACT sources at a facility. A separate HBEL would apply to each facility based on the combination of physical stack parameters from each subject boiler.
The physical parameters incorporated into the screening-level modeling used to develop the tables should include the basic parameters that govern the dispersion and are. These include:
* Source characteristics, such as stack height and building height for each MACT source;

* Distance to property line;

* Maximum height of on-site structures;

* Presence of highest nearby terrain (e.g., within 5 km).
Tier 1 HBELs look-up tables would account for various combinations of these physical parameters. Because the look-up tables are based on screening-level dispersion models, such as SCREEN3 or AERSCREEN, that are designed to be conservative, this would provide the “ample margin of safety” as required by 112(d)(4). Thus, EPA can assure that compliance with the Tier 1 HBELs will mean that actual concentrations to which the public could be exposed are below established health effects threshold levels. The screening modeling that EPA would use to develop Tier 1 HBELs may address both chronic (annual average) and acute (maximum 1-hour) threshold effects, as appropriate. The determination of whether HBELs are appropriate for acute effects, chronic effects or both types of effects depends on whether an acute or chronic effect for

a threshold HAP is universally demonstrated to be more limiting. EPA may conclude, as it did in 2004, that protection against chronic health effects will inherently safeguard against acute health effects. An example of the possible structure of Tier 1 HBEL look-up tables is provided in Appendix H to these comments.

Tier 2 HBELs – Based on Site-specific Dispersion Modeling

If facility boiler emissions exceed the conservatively derived Tier 1 HBELs or if the regulatory agency judges that the physical layout or dispersion environment of the site make it inappropriate to apply the Tier 1 HBEL look-up tables, a facility would conduct site-specific dispersion modeling. Site specific modeling would use source specific stack parameters and apply EPA's state-of-the-science dispersion model AERMOD with five years of representative meteorological data. Model receptors could be placed at the boundary and in a specified grid representing off-site locations out to 5 km or could use site-specific receptor locations such as have been previously established for ambient air quality modeling.

In this modeling, the combined impact of the specific HBEL HAPs would be modeled for the appropriate averaging times (1-hour for acute and annual average for chronic) and compared to established health effects benchmarks, such as those provided in Section B, Table 1 of these comments. As noted, to address acute effects of acid gases, it is appropriate to add the hazard quotients (HQ) (modeled concentration divided by health effects threshold) for HCl, Cl_2, and HF to compute a hazard index (HI) for acute respiratory effects. A HI < 1.0 indicates that there is no incremental health effect. To address chronic effects of acid gases, it is appropriate to add the HQs (modeled concentration divided by health effects threshold) for HCl and Cl_2 to compute a hazard index (HI) for chronic respiratory effects. As noted, for chronic effects of HF, HCN and Mn it is appropriate to evaluate threshold effects separately for each pollutant. To establish HBELs for each boiler, the facility would use the modeling to determine the combination of peak 1-hour and annual average emission rates that result in a HI or HQ of 1.0. Thus, if emissions from each subject boiler are less than these site-specific HBELs it will be assured that exposure will not exceed health effects thresholds as required under CAA Section 112(d)(4).

Comment: In establishing compliance with HBELs, a facility will need to estimate upper-limit short-term emissions to assess acute threshold health effects and annual average emissions to assess chronic threshold effects. Realistic, yet conservative, HAP emission rate assumptions should be used in determining compliance with HBELs under 112(d)(4) rather than across-the-board worst-case assumptions because using worst-case emission assumptions will materially overestimate both chronic and acute risk. EPA contends that a reason not to include a risk option such as HBEL is that there is lack of available data for HAP emissions from boiler sources. Although care must be taken in estimating emissions, for the HAPs under consideration,

standardized methods could be established to develop suitably conservative emission estimates based either on fuel data or emission tests.
If fuel testing is used, emissions for HCl, Cl2, HF, and Mn may be conservatively estimated based on knowledge of fuel type, measured fuel concentrations and use rate, assuming 100% of the HAP is released to the atmosphere. If source testing is used it will automatically account for a degree of HAP removal through bottom ash, and emission controls. Because it is recognized that a single fuel sample or source test may not be representative of the long-term average, multiple fuel samples taken over an established period could be required. If a boiler has variable fuel sources,(e.g., coal from different mines or various types of wood), a number of samples from each source type would also be required. The variability of emissions would then be used following standardized data analysis methods to estimate the 95th percentile average emission factor to be used in the chronic HBEL compliance determination and combined with permitted annual fuel use. To account for short-term (hour-by hour) fluctuations the maximum hourly fuel use could be applied, along with a statistical estimate of the 95th percentile concentration for each HAP to estimate emissions for the acute HBEL.
This method of evaluating short-term fluctuations is highly conservative because the modeling used to develop the HBELs implicitly assumes that a source continuously emits each HAP at its 95th percentile maximum emission rate and that the worst-case emissions occur concurrently with worst-case dispersion conditions (Paine and Heinold 2010). The degree to which this highly conservative assumption affects HBEL certification depends on whether the acute HBEL or the chronic HBEL is limiting.
A similar procedure can be applied based on source test data. In the case where emission controls are in-place, the source could have the option of measuring uncontrolled or controlled emissions. If emission controls are used during the source test, additional parameters related to the control device would need to me monitored.

Comment: While the purpose of the MACT regulations is to reduce health impacts from Hazardous Air Pollutants, the "eliminate emissions at any cost" strategy that EPA is utilizing in establishing these MACTs has no correlation to actual health impacts. In fact, with the exception of Hg, HCI, and dioxin/furans, these proposed regulations do not establish limitations on any HAPs but instead draw on generalized correlations to criteria air pollutants for which standards are proposed. In effect, EPA is establishing limitations for pollutants regulated under other sections of the Clean Air Act; limitations which could not be justified otherwise. Therefore, Health Based Compliance Alternatives similar to those included in the prior version of the Agency's boiler MACT should be included. It would likely be determined that many small to moderate size boilers have little to no health-based impacts from their HAP emissions, rendering the addition of costly emissions controls unnecessary.

Comment: Particularly in these tough economic times, EPA should embrace standards that both provide the same HAP benefits while greatly reducing costs. Section 112(d)(4) allows EPA to establish these alternative standards that have clearly demonstrated both their ability to be protective of the environment and far less costly than EPA's proposed approach. After all of the years EPA has had to develop these standards, and all of the data that have been submitted to EPA, EPA should evaluate establishing these alternative and equivalent standards.

Comment: EPA notes that it would need additional facility-specific emissions information to develop model plants for the eleven subcategories considered in the proposed rule. This would allow EPA to conduct the dispersion modeling necessary to establish health-based emission limits. EPA should instead establish a process where EPA publishes target health-based concentration based limits (annual average concentrations and/or hourly average concentrations, if needed). EPA should then require the owner/operator to perform dispersion modeling studies to predict the maximum off-site concentrations of these HAPs or perhaps of HCl if used as a surrogate for the other air contaminants. This type of approach would place the work of conducting the dispersion modeling on the owner/operator and then state agencies and/or EPA could review the studies and issue a final determination of whether or not the HBCA criteria is met.

Comment: EPA should utilize a "health-based" approach under Clean Air Act 112(d)(4) in establishing ICI Boiler MACT emission limits. EPA should utilize a "health-based" approach, where possible, in establishing HAP emission control requirements for ICI Boilers. Once ICI Boilers control HAPs to a level protecting public health, with an ample margin of safety, no further reduction in HAPs should be necessary or required.

Comment: An HBCA can be implemented as described in the vacated Boiler MACT rule. In the original 2004 Boiler MACT rule, EPA set forth a comprehensive procedure for sources to implement the requirements of an HBCA-based emission limit. These procedures consisted of look-up tables as a screening tool for facilities to easily determine if their HBCA would be applicable to the specific location. As an alternate to the look-up tables, facilities could perform a site specific risk assessment using state-approved air dispersion models. GP supports a similar approach for this rulemaking.

Comment Excerpt Number: 72

Comment: While EPA has discretion in deciding whether to set HBELs under 112(d)(4), the Agency cannot be arbitrary and capricious in making such a decision. The proposed HCl and PM emissions limitations for all types of industrial boilers are exceedingly stringent. Affected sources will have to spend tens of millions of dollars in order to meet the standards and, as even EPA predicts, a significant number of existing units simply will not be able to meet the standards and will be required to shut down. In addition, the work that EPA performed in support of the HBELs included in the 2004 rule demonstrates that the proposed standards are far more stringent than needed to assure the protection of public health with an ample margin of safety. The costs and burdens on affected sources and the degree of control needed to provide adequate health and environmental protection are both key factors that should be considered by the Agency in deciding whether to adopt HBELs in the Industrial Boiler MACT.

In the proposed rule, EPA completely ignores these factors. The Agency's discussion of HBELs includes no assessment whatsoever of the costs that might be avoided by adopting HBELs for HCl or manganese. As to potential effects on health or environment, EPA simply raises implementation questions and asserts a lack of information to resolve the questions. Such an approach is facially inadequate in light of the extensive policy, scientific, and technical assessment developed in support of the HBELs in the 2004 Industrial Boiler MACT standard. In short, EPA's failure to fully consider key factors that are relevant to making an informed decision as to whether HBELs should be adopted is arbitrary and capricious.

Comment Excerpt Number: 73

Comment: EPA asserts in the proposed rule that its decision to not propose HBELs "is not contrary to EPA's prior decisions where we found it appropriate to exercise the discretion to invoke the authority in section 112(d)(4) for HCl, since the circumstances in this case differ from previous considerations." 75 Fed. Reg. 32032. In contrast to "other source categories for which EPA has exercised its authority under section 112(d)(4)," EPA explains that boilers and process heaters are more likely to be co-located with other HAP sources and are often located in heavily populated urban areas where many other HAP sources exist. Id. The Agency concludes that, "These factors make an analysis of the health impact of emissions from these sources on the exposed population significantly more complex than for many other source categories, and therefore make it more difficult to establish an ample margin of safety." Id.

These assertions fail to reflect the fact that the industrial boiler source category is one of the few categories where EPA has previously "found it appropriate to exercise the discretion to invoke the authority in section 112(d)(4).” Id. As a result, EPA has already drawn conclusions as to how to deal with possible co-location with other HAP sources and how to appropriately consider HAP emissions from other nearby sources. These are not issues of first impression generally or in the specific context of industrial boilers and process heaters. The questions have been asked and answered in 2004 in the context of notice and comment rulemaking for the industrial boiler and process heater source category.

Thus, EPA is mistaken in asserting that its decision not to propose HBELs is “not contrary to EPA’s prior decisions.” Id. The decision not to propose HBELs is flatly inconsistent with EPA’s prior determination that HBELs are appropriate and justified for the industrial boiler and process heater source category. EPA’s failure to acknowledge its prior determination and failure to explain why it has raised as questions issues that previously were resolved (such as how to consider co-located HAP sources and nearby HAP sources) render its decision not to propose HBELs arbitrary and capricious.

Other

Other – Merging of Phase I and Phase II Test Data

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 25

Comment: The most critical shortcoming in EPA’s data analysis is the merging of test results reported by Phase I ICR respondents with results from the Phase II mandatory test program into a single database. This database was used to identify "best performers" in each subcategory and calculate proposed emission limits. In merging the test results from Phase I and Phase II, EPA implicitly assumed the data were comparable without conducting a detailed review of the actual stack sampling protocol and associated laboratory analysis reports.

EPA issued a set of instructions for the Phase II ICR testing program. These instructions covered: the sampling methods to be used; minimum sampling volumes for different pollutants; how non-detect values should be handled and reported; how boiler heat input rates should be calculated; and the data reporting and submission procedures, i.e., required use of EPA’s Electronic Reporting Tool (ERT).24 The instructions were silent on how method detection limits should be determined, and the methods themselves do not address detection limits.

The initial instructions distributed to the facilities selected by EPA for sampling contained a number of unclear or ambiguous requirements, which necessitated six subsequent Q&A and guidance documents and an EPA webinar to clarify what EPA really wanted. Unfortunately, since EPA set a four month time frame for the tests to be performed and results to be submitted to EPA, many companies had already contracted with stack sampling firms and had an agreed-upon scope of work before EPA had made final clarifications to the instructions. Thus, it appears that not all of the Phase II stack testing was conducted in accordance with EPA's final instructions and guidance.

Emission tests not conducted as part of the Phase II ICR would not have satisfied all of the criteria established by EPA. For example, the handling and reporting of non-detects were different because EPA stack testing methods are silent on these points. However, this is a critical issue when comparing emission test results to identify units with the lowest emission rates.

Response: EPA acknowledges the concerns of the commenter about merging test data. In the final emission test database we flag the source of the emission test data as either Phase I or Phase II, or other voluntary data submittal so that stakeholders can identify the source of the data. Given the large affected source category and comments from many others that suggest the current combined dataset is insufficiently representative, we believe it is inappropriate to only use data submitted from the Phase II ICR for the basis of the standard. We have also reviewed and updated several ICR Phase I test results from the best performing units in order to reduce the inconsistent treatment of mercury fractions and detection limits, as time allowed.

Appendix A: Commenter Tables

The following 3 tables detail all of the comments received by EPA in response to Proposed Rule published in the Federal Register on June 4, 2010 at 75 FR 31895, *National Emission Standards for Hazardous Air Pollutants for Major Source Industrial/Commercial/Institutional Boilers and Process Heaters.*

Table 1 is the comprehensive list, by Document Control Number (DCN), the number assigned by the EPA docket center to identify each document in the docket.

Table 2 displays the number of form letters submitted to EPA-HQ-OAR-2002-0058. "Form Letter Group" is the description given to a form letter based on the industry or non-governmental organization that coordinated the comment effort. The number in parentheses after the Form Letter Group is the number of identical letters received for each form letter group.

Table 3 identifies comments that specifically reference other comment letters written in response to this proposed rule or incorporated by reference another comment written in response to this proposed rule, effectively supporting some or all of the opinions expressed by another commenter.
