EPA's Responses to Public Comments on EPA's *National Emission Standards for Hazardous Air Pollutants for Major Source Industrial Commercial Institutional Boilers and Process Heaters*

Volume 2 of 2

Comments letters and transcripts of the public hearings are also available electronically through h*ttp://www.regulations.gov* by searching Docket ID *EPA-HQ-OAR-2002-0058.*

FOREWORD

This document provides EPA's responses to public comments on EPA's Proposed *National Emission Standards for Hazardous Air Pollutants for Major Source Industrial Commercial Institutional Boilers and Process Heaters*. EPA published a Notice of Proposed Rulemaking in the Federal Register on June 4, 2010 at 75 FR 32005. EPA received comments on this proposed rule via mail, e-mail, facsimile, and at three public hearings held in Washington, DC, Houston, Texas, and Los Angeles, California in June 2010. Copies of all comments submitted and transcripts for the public hearings are available at the EPA Docket Center Public Reading Room. Comments letters and transcripts of the public hearings are also available electronically through h*ttp://www.regulations.gov* by searching Docket ID *EPA-HQ-OAR-2002-0058.*

Due to the size and scope of this rulemaking, EPA paraphrased a limited amount of major comment themes in the preamble of the final rule. This document contains the verbatim comments provided by each commenter extracted from the original letter or public hearing transcript.

For each comment, the name and affiliation of the commenter, the document control number (DCN) assigned to the comment letter, and the number of the comment excerpt is provided. *Table 1* of this document provides a complete listing of the DCN and affiliations included in this document. In some cases the same comment excerpt was submitted by two or more commenters either by submittal of a form letter prepared by an organization or by the commenter incorporating by reference the comments in another comment letter. Rather than repeat these comment excerpts for each commenter, EPA has listed the comment excerpt only once and provided a list of all the commenters who submitted the same form letter or otherwise incorporated the comments by reference in *Tables 2 and 3* at the end of this document.

Several of EPA's responses to comments are provided immediately following each comment excerpt. However, in instances where several commenters raised similar or related issues, EPA has grouped these comments together and provided a single response after the first comment excerpt in the group and referenced this response in the other comment excerpts. In some cases, EPA provided responses to specific comments or groups of similar comments in the Preamble to the final rulemaking. Rather than repeating those responses in this document, EPA has referenced the Preamble or the appropriate technical support document for a description of the analysis included in the final rule. In other cases EPA has provided a general response at the beginning of each section of this document.

Parallel with this rulemaking effort are three separate, but related rulemakings that may be of interest to stakeholders. These three rules are: *National Emission Standards for Hazardous Air Pollutants for Area Source Industrial/Commercial/Institutional Boilers* (Docket ID: EPA-HQ-OAR-2006-0790); *Identification of Non-Hazardous Secondary Materials That Are Solid Waste* (Docket ID: EPA-HQ-RCRA-2008-0329); and *Standards of Performance for New Stationary Sources and Emission Guidelines for Existing Sources: Commercial and Industrial Solid Waste Incineration Units* (Docket ID: EPA–HQ–OAR–2003–0119).
Given the identical proposal dates, and the related nature of these other rules, many commenters submitted comments to this rulemaking docket that were specific to one of these related rulemakings. Some commenters submitted a single DCN with comments on all four rules while others submitted a separate DCN specific to each rule. Many commenters submitted identical

comments to all of these dockets. In order to reduce duplicative comments, this document flags comments associated with any of the above three related rulemakings as out-of-scope comments for this response to comment document. To the extent that the commenter submitted these comments to the appropriate rulemaking document, responses have been developed in the response to comment documents for each of these related rulemakings. For this reason, EPA encourages the public to read the other response to comment documents prepared for these three other rulemakings as they may contain topics relevant to these other rulemakings.

Rationale for Regulated Pollutants

Choice of Regulated Pollutants: Surrogates

Commenter Name: Norbord Industries
Commenter Affiliation: Norbord Industries
Document Control Number: EPA-HQ-OAR-2002-0058-0854.1
Comment Excerpt Number: 8

Comment: EPA has focused on setting limits with surrogates such as PM for metals and CO for HAPs. While establishing a PM standard and CO standard seems reasonable considering the potential complexity of testing for numerous pollutants, it also seems equally reasonable to establish an alternative standard for metals and other HAPs that focuses on the actual reduction of HAPs. The stringent requirements of Boiler MACT will make it difficult to meet some portions of the standard for many facilities such as ones with high HCl and PM (requiring multiple control devices). Though I could not predict what an alternative metal standard might entail it would likely increase the number of control options to facilities.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2917.1, excerpt 9.

Commenter Name: Chris Greissing
Commenter Affiliation: Industrial Minerals Association
Document Control Number: EPA-HQ-OAR-2002-0058-2740.2
Comment Excerpt Number: 18

Comment: EPA justifies the use of PM as a surrogate for non-mercury metallic HAP on the basis that it "will also eliminate the cost of performance testing to comply with numerous standards for individual non-mercury metals." However, the supposed cost savings is illusory because PM CEMS certification is expensive. PM CEMS require a rigorous initial certification per 40 CFR 60 Appendix B Performance Specification 11, in which fifteen (15) Reference Method tests are conducted to develop the PM analyzer correlation. In addition, a Relative Response Audit must be conducted annually and a Response Correlation Audit must be performed every three years. The cost of initial certification could cost tens of thousands of dollars per unit with subsequent audits costing $5K to $8K per year.

Response: The non-Hg metal HAP are very likely to be present in the particulate phase and will be captured along with the filterable PM in the primary PM control device. The partitioning of the metal HAPs is very complicated and can depend upon the fuel type, the form of the metals in the fuel, other constituents in the fuel and the time-temperature profile of the post-combustion environment. EPA's Office of Research & Development has conducted studies that showed good control of the non-Hg metal HAP followed good control of bulk PM (filterable) across the primary PM control device. Furthermore, the applicability of PM CEMS is only to units >250 MMBtu/hr.

Commenter Name: Los Angeles Public Hearing Transcript
Commenter Affiliation: See transcript for detailed list of commenters
Document Control Number: EPA-HQ-OAR-2002-0058-1778
Comment Excerpt Number: 72

Comment: In any case, as should be the case with Boiler MACT facilities should have the option to comply with an emission limit for the HAP of concern rather than the surrogate; e.g., as an example, POM in lieu of CO.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2917.1, excerpt 9.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 191

Comment: Surrogates
CIBO supports the use of surrogates in the proposed Boiler MACT. EPA's use of surrogates for Non-mercury metallic HAP, Non-metallic inorganic HAP and Non-dioxin organic HAP is fully supported by long-standing case law. The D.C. Circuit has clearly held that "EPA may use a surrogate to regulate hazardous pollutants if it is reasonable to do so." Mossville Environmental Action Now v. EPA, 370 F.3d 1232, 1242 (D.C. Cir. 2004); Nat'l Lime, 233 F.3d at 634. In assessing the reasonableness of EPA's use of a surrogate in the Nat'l Lime case, the D.C. Circuit found that EPA satisfied this burden by demonstrating that there were always HAP metals in particulate matter (the surrogate), and thus that the removal of the particulate matter removed the HAP metals. Nat'l Lime, 233 F.3d at 639.

EPA's use of surrogates is well-supported by longstanding case law. Surrogates may be used for compounds regulated under section 112 where it is reasonable to do so and not otherwise contrary to law. Nat'l Lime Ass'n v. EPA, 233 F.3d 625, 637 (D.C. Cir. 2000); see also Kennecott Greens Creek Mining Company v. Mine Safety and Health Administration, 476 F.3d 946, 955 (D.C. Cr. 2007) ("there is nothing inherently problematic with an agency regulating one substance as a surrogate for another substance") (citing Nat'l Lime). In assessing the reasonableness of EPA's use of a surrogate, courts look to whether EPA has demonstrated a correlation between the HAP and the surrogate. Id.; see also Mossville Envt'l Action Now v. EPA, 370 F.3d 1232, 1242 (D.C. Cir. 2004) (invalidating use of vinyl chloride as surrogate where EPA failed to demonstrate correlation to HAP); Sierra Club v. EPA, 353 F.3d 976, 985 (D.C. Cir. 2004). While EPA's use of surrogates is supported by case law and by CIBO when appropriate, the following are comments that address outstanding issues with regard to EPA's use of surrogates in the Proposed Rule.

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 3

Comment: MidAmerican Does Not Support the Use of Surrogates for Certain Hazardous Air Pollutants – The use of surrogates is legally permissible. Specifically, the U.S. Court of Appeals in National Lime Association v. EPA [Footnote: 233 F.3d 625.} held that the EPA may use reasonable surrogates in setting technology based standards under section 112(d)(2) and (3) where the target pollutant is present in the surrogate, the control technology indiscriminately captures both the target and the surrogate and the control of the surrogate is the only means by which facilities can achieve reductions in the target HAPs.

In general terms, MidAmerican is supportive of the use of certain surrogates in this proposed rule. There is a large number of HAPs potentially present in emissions and as a result there are high costs and problems associated with accurately measuring and monitoring these HAP emissions. The use of surrogates can be beneficial to regulated entities by reducing the costs of both implementation and compliance with this proposed rule.

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 67

Comment: ACC supports EPA's proposed use of surrogates. [The use of surrogates is supported by longstanding case law. The D.C. Circuit has clearly held that "EPA may use a surrogate to regulate hazardous pollutants if it is reasonable to do so and not otherwise contrary to law." In assessing the reasonableness of EPA's use of a surrogate in the Nat"l Lime case, the D.C. Circuit court has looked to whether EPA has satisfied this burden by demonstrating a correlation between the HAP and the surrogate, and thus that the removal of the surrogate matter removed the HAP. Nat"l Lime Ass"n v. EPA 233 F.3d 625,at 639 (D.C. Cir. 2000); Mossville Envt"l Action Now v EPA 370 F.3d 1232, 1242 (D.C. Cir. 2004) and Sierra Club v. EPA, 353 F.3d 976, 985 (D. C. Cir. 2004).]

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Paul J. Allen
Commenter Affiliation: Constellation Energy
Document Control Number: EPA-HQ-OAR-2002-0058-3164
Comment Excerpt Number: 3

Comment: Constellation supports use of surrogates for monitoring organics. Major source power plants already have Permits to Operate and/or Title V Permits that contain limits on emissions of criteria pollutants including CO and PM. Therefore, we suggest using these pollutant as surrogates, CO as a surrogate for non-dioxin organic HAP and PM a surrogate for non- and semi-volatile metal HAP, is suggested.

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Richard Rosvold
Commenter Affiliation: Xcel Energy Services, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2955.1
Comment Excerpt Number: 5

Comment: In general, we support the use of surrogates, rather than requiring limits for each individual hazardous air pollutant (HAP). Having individual limits for each chemical would be burdensome and would not provide any additional public health or environmental benefit.

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 9

Comment: The Agency's proposed use of surrogates is appropriate as it ensures environmental protection while reducing the measurement burden on affected facilities. We note, however, that proposed CO emission limits for liquid- and gas-fired boilers are far beyond what is required to ensure HAP emissions are minimized.

ACC offers detailed suggestions on how EPA can improve the effort to consider fuel variability in the floor setting process.

Response: See the preamble for discussion on revised CO limits.

Commenter Name: Roy W. Wood
Commenter Affiliation: Eastman Kodak Company
Document Control Number: EPA-HQ-OAR-2002-0058-2917.1
Comment Excerpt Number: 9

Comment: An alternative means of establishing HAP compliance for the HAP surrogates, PM and CO, should be provided
The boiler MACT establishes emissions limits for 3 HAPs (mercury, HCl, dioxins) and two HAP surrogates (PM and CO). Control of the HAP surrogates is not required under the CAA. Rather EPA has proposed that these are reasonable surrogates for certain HAPs and these surrogates Junction as a more cost-effective means of controlling these HAPs. This reasoning is only valid to the extent that the selected surrogates truly correlate with the design HAPs. While there is some correlation between PM and HAP metals and some correlation between CO and organic HAPs, the correlation breaks down under a number of situations including low metals fuels and NOx reburn.

Because HAPs and the chosen surrogates do not correlate well across all boiler types, alternative compliance options should be available for the PM and CO standards which demonstrate compliance with HAP emissions instead of compliance with the surrogate standard.

Response: Carbon monoxide is often used as an indicator of combustion conditions. Under conditions of ideal combustion, a carbon-based or hydrocarbon fuel will completely oxidize to produce only CO2 and water. Under conditions of incomplete or non-ideal combustion, a greater amount of CO will be formed. With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the production of CO would also limit the production of organics. Because the non-Hg HAP metals are expected to be controlled using the same technologies that are applied for PM control, it seems logical to conclude that setting a standard that results in maximum achievable control of PM will result in good control of the non-Hg HAP metals.

Commenter Name: Barry Christensen
Commenter Affiliation: Occidental Chemical Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2848.1
Comment Excerpt Number: 15

Comment: OCC supports EPA's use of surrogate parameters. For example, carbon monoxide is the more practical parameter to measure than individual organic HAPs. Similarly, establishing and controlling particulate is a practical way to limit the non-mercury metals. It is too costly and impractical to monitor and directly limit each individual HAP.

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Sarah E. Amick
Commenter Affiliation: Rubber Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 18

Comment: EPA's use of surrogates is well-supported by longstanding case law. Surrogates may be used for compounds regulated under section 112 where it is reasonable to do so and not otherwise contrary to law. Nat'l Lime Ass'n v. EPA, 233 F.3d 625, 637 (D.C. Cir. 2000); see also Kennecott Greens Creek Mining Company v. Mine Safety and Health Administration, 476 F.3d 946, 955 (D.C. Cr. 2007) ("there is nothing inherently problematic with an agency regulating one substance as a surrogate for another substance") (citing Nat'l Lime). In assessing the reasonableness of EPA's use of a surrogate, courts look to whether EPA has demonstrated a correlation between the HAP and the surrogate. Id.; see also Mossville Envt'l Action Now v. EPA, 370 F.3d 1232, 1242 (D.C. Cir. 2004) (invalidating use of vinyl chloride as surrogate where EPA failed to demonstrate correlation to HAP); Sierra Club v. EPA, 353 F.3d 976, 985 (D.C. Cir. 2004).

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Commenter Name: Gary W. Kruger
Commenter Affiliation: Morton Salt
Document Control Number: EPA-HQ-OAR-2002-0058-2883.1
Comment Excerpt Number: 31

Comment: Morton Salt supports the use of surrogates in the proposed Boiler MACT. The D.C. Circuit has clearly held that EPA may use a surrogate to regulate hazardous pollutants if it is reasonable to do so. Mossville Environmental Action Now v. EPA, 370 F.3d 1232, 1242 (D.C. Cir. 2004); Nat'l Lime, 233 F.3d at 634. In assessing the reasonableness of EPA's use of a surrogate in the Nat'l Lime case, the D.C. Circuit found that EPA satisfied this burden by demonstrating that there were always HAP metals in particulate matter (the surrogate), and thus that the removal of the particulate matter removed the HAP metals. Nat'l Lime, 233 F.3d at 639.

Response: EPA acknowledges the comment and agrees. It has finalized CO, PM, and HCl as surrogates in the final rule.

Choice of Regulated Pollutants: THC vs. CO vs. Other Organic HAP

Commenter Name: Thomas J. Christofk
Commenter Affiliation: Placer County Air Pollution Control District
Document Control Number: EPA-HQ-OAR-2002-0058-1598.1
Comment Excerpt Number: 2

Comment: Placer County Air Pollution Control District (PCAPCD) supports the use of a CO limit as a surrogate for non-dioxin organic hazardous air pollutants. CO limits, and the use of CO continuous emissions monitoring systems, are a part of existing Placer County and State of California biomass boiler operating permits.

Response: EPA acknowledges the comment and agrees. It has finalized CO as a surrogate in the final rule.

Commenter Name: Los Angeles Public Hearing Transcript
Commenter Affiliation: See transcript for detailed list of commenters
Document Control Number: EPA-HQ-OAR-2002-0058-1778
Comment Excerpt Number: 78

Comment: Your standard identifies specific
chemicals that we feel is not adequate. There are over
0 00 plus toxic HAP chemicals that have been identified
and we want a standard to be applied to every single one
of them. You have stated in there that you have
identified or called a category of a surrogate or CO,
for example. Well, you can’t compare a thousand pounds
of benzene to a thousand pounds of CO by averaging.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15.

Commenter Name: James P. Brooks
Commenter Affiliation: Maine Department of Environmental Protection, Bureau of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-2746.1
Comment Excerpt Number: 1

Comment: In 2009, the Maine DEP requested stack testing information from Maine's biomass and multi-fuel boilers to evaluate the relationship between CO, NOx, POM and metallic HAPs. The Maine DEP submitted its report Carbon Monoxide Variability in Maine Wood-Fired Boilers to EPA in March 2010. A copy of the report accompanies this letter for submission to the docket. The Maine DEP's analysis revealed wide variations in CO emission rates from single units resulting from variations in biomass moisture content and the types of additional materials co-combusted with the biomass. In the report, we concluded:

EPA should NOT utilize CO as a surrogate for HAP in wood fired and multi-fueled boilers. The data illustrates that CO is extremely variable in wood fired/multi-fueled boilers. An inappropriately low CO standard may result in facilities burning significantly more fossil fuels to reduce variability and meet a CO standard. Alternatively, a facility may choose add-on CO control equipment which would control CO but not HAPs.

EPA should develop a standard for gaseous HAP using VOC, TOC, or THC as a surrogate as utilized in several other combustion NESHAP.

If EPA chooses to use CO as a surrogate for HAP, EPA should take into account the inherent variability encountered when combusting only wood.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Commenter Name: Arthur N. Marin
Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 2

Comment: NESCAUM has serious concerns with the proposed CO limits in both rules. First and foremost, NESCAUM states do not concur with the assumption that, at lower emission levels, CO is an appropriate surrogate for reducing polycyclic organic matter (POM) emissions. Analyses by states of this issue support this conclusion. If EPA's position is that increased combustion will result in lower emission levels of organics, then we suggest that EPA use a combustion efficiency limit and test method rather than a CO standard. For existing units, EPA should require annual tune-up and testing of combustion efficiency (oxidative). For new units, EPA should require that they meet the U.S. Department of Energy's AFUE standards for direct heating devices and boilers or ASHRAE155p standards.
If EPA chooses to continue to use CO as a surrogate for POM emissions, we recommend that it re-evaluate its approach towards emission limits and control options for CO. Increasing combustion efficiency may reduce POM emissions, but the use of CO controls may not. Furthermore, the proposed CO limits may be unachievable for some existing units. If such a unit has NOx limits, then it will need to install add-on CO controls to these units, likely CO catalysts, which will do nothing to reduce HAP emissions. If a unit does not have NOx emission limits, it

may increase NOx emissions in order to reduce its CO emissions, once again with little impact on its overall HAP emissions. NESCAUM recommends that EPA use a multi-pollutant approach to re-evaluate the proposed CO emission limits in light of the potential negative impacts of the CO limits on the emissions of other air pollutants.

Response: Carbon monoxide is often used as an indicator of combustion conditions. Under conditions of ideal combustion, a carbon-based or hydrocarbon fuel will completely oxidize to produce only CO_2 and water. Under conditions of incomplete or non-ideal combustion, a greater amount of CO will be formed. With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the production of CO would also limit the production of organics. As such, EPA is not including other options for compliance with respect to non-dioxin organic HAP; all units must meet CO limits.

Based on comments received there was insufficient data to determine if a lower threshold for CO exists. For example different thresholds were provided (100 vs 500 ppm). In the absence of specific data we computed the CO MACT floors using the data available. Also, since proposal many of the CO limits have increased, see the preamble for further discussion.

Regarding the use of oxidation catalysts to reduce organic HAP, there are permits for biomass units through the Florida Department of Environmental Protection which show organic HAP reductions via oxidation catalysts. See information for DEP File No. 0810226-001-AC.

Commenter Name: Robert R. Scott
Commenter Affiliation: New Hampshire Department of Environmental Services, Air Resources Division
Document Control Number: EPA-HQ-OAR-2002-0058-2734.1
Comment Excerpt Number: 2

Comment: The proposal uses carbon monoxide (CO) as a surrogate for polycyclic organic matter (POM) and other urban organic HAPs.

EPA is proposing to use CO as a surrogate for organic HAPs, including POM, emitted from various fuels burned in boilers because the presence of CO is an indicator of incomplete combustion and possibly an indicator of elevated organic HAP emissions. In addition, monitoring equipment and measuring of CO is more readily available and cost effective than measuring and monitoring individual organic HAPs. While NHDES recognizes that using a surrogate for HAPs in this proposal is more practical than imposing individual standards for each specific HAP, NHDES is concerned that setting a CO limit in this regulation could potentially result in facilities installing CO controls to meet the CO emission limits in the rule instead of improving the efficiency of the boiler to reduce HAP emissions, especially if the CO emission limitations set by the rule are exceedingly restrictive. There has been some indication from various studies that reducing CO emissions to reduce HAP emissions is only effective to a certain point and that below that level, HAP emissions are no longer effectively reduced.

NHDES recommends that if EPA continues to use CO as a surrogate for HAPs, that EPA research the available data to confirm this break even point and set CO emission levels such that the intent of the rule (reduction in HAP emissions) is actually achieved by the rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Comment Excerpt Number: 3

Comment: EPA established limits for CO, but should focus on ensuring boilers have good combustion practices.

Response: See the preamble for discussion on setting MACT standards and how CO limits were modified.

Commenter Name: James P. Brooks
Commenter Affiliation: Maine Department of Environmental Protection, Bureau of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-2746.1
Comment Excerpt Number: 5

Comment: EPA's own proposed standards support the conclusion that CO is an inappropriate surrogate for organic HAPs. Dioxin is an organic HAP, but is addressed independent of the other organic HAP supposedly covered by the CO standards. As required by Section 112, the proposed standards are based on actual emission rates reported by facilities. Where the proposed dioxin limits were low, CO limits were higher and vice versa. We believe this supports our findings that CO emissions do not trend with organic HAPs, and therefore CO is a poor surrogate. We recommend that EPA more carefully consider these relationships and the implications of regulating CO emissions instead of EPA's target pollutants.

Response: Carbon monoxide is often used as an indicator of combustion conditions. Under conditions of ideal combustion, a carbon-based or hydrocarbon fuel will completely oxidize to produce only CO2 and water. Under conditions of incomplete or non-ideal combustion, a greater amount of CO will be formed. With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the production of CO would also limit the production of organics. Dioxins/furans, however, are produced by mechanisms (often catalytic) downstream of the combustion zone and are not related to the amount of CO present in the flue gas. EPA does not have sufficient data to set a separate emission limit for organic HAP.   As such, EPA is not including other options for compliance and all units must meet CO and dioxin/furan limits.

Based on comments received there was insufficient data to determine if a lower threshold for CO exists. For example, different thresholds were provided (100 vs 500 ppm). In the absence of specific data we computed the CO MACT floors using the data available. Also, since proposal many of the CO limits have increased, see the preamble for further discussion.

Regarding the use of oxidation catalysts to reduce organic HAP, there are permits for biomass units through the Florida Department of Environmental Protection which show organic HAP reductions via oxidation catalysts. See information for DEP File No. 0810226-001-AC.

Comment: The background information indicates the CO limitations are included as a surrogate for organic HAPs. We question the use of CO as a surrogate on a number of points. [See submittal for Tables]
EPA consider development of an alternative surrogate for organic HAP such as THC.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council

Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 13

Comment: EPA's choice of CO as a surrogate for organic HAPs violates the requirements of CAA section 112(c)(6).
Section 112(c)(6) of the Act requires "[w]ith respect to" certain listed highly toxic HAPs, including the carcinogenic POM and PCBs, the Administrator "shall ...list categories and subcategories of sources assuring that sources accounting for not less than 90 per centum of the aggregate emissions of each such pollutant are subject to standards under subsections [112](d)(2) or (d)(4) ...." 42 U.S.C. § 7412(c)(6)(emphasis added). Section 112(c)(6) thus provides the public with extra protection from these exceptionally toxic HAPs – by requiring listed sources of each such pollutant to be subject to MACT-based standards. Regardless of what authority EPA might have to use surrogates for other hazardous air pollutants, the agency must set specific emission standards under § 112(d)(2) or (d)(4) for the highly toxic HAP enumerated in § 112(c)(6).

In 1998, EPA listed 'industrial coal combustion' industrial oil combustion,' 'industrial wood/wood residue combustion,' commercial coal combustion,' 'commercial oil combustion,' and 'commercial wood/wood residue combustion,' under section 112(c)(6). 75 Fed. Reg. 32,008, 32,042 (citing 63 Fed. Reg. 17838, 17848 (April 10, 1998)). While EPA asserts that the 1998 listing was on the basis of emissions of POM and mercury, 75 Fed. Reg. 32,008, that alone is not enough to permit the Agency to escape the requirement to set MACT standards for all the 112(c)(6) pollutants it now knows are emitted by ICIBPH, which include not only POM, and mercury, but also PCBs.

Specifically, EPA claims that it has met its obligations under § 112(c)(6) by setting by setting carbon monoxide (CO) standards, and that "POM is effectively reduced by the combustion and post-combustion practices require to comply with the [other] CAA section 112 standards." 75 Fed. Reg. 32,042. But this is not enough to satisfy the requirements of the stateute. First, EPA makes no mention of the other §112(c)(6) pollutants emitted by ICIBPH, and how they might be affected by this proposal. Second, nothing in the statute's language authorizes EPA to use a surrogate to regulate POM, or any of the other pollutants specifically enumerated in §112(c)(6), including the PCBs also emitted by ICIBPH. EPA's attempt to do so in fact contravenes the plain language requirements of the statute. Third, § 112(c)(6) requires the Agency to "assure" that sources of these pollutants are regulated by MACT-based standards – so that "not less than 90 percentum of the aggregate emissions of each such pollutant" are so regulated. 42 U.S.C. § 7412(c)(6). It is implausible to quantify the degree to which emissions of POM and PCBs are lowered by standards that only set limits on – and demand compliance for the CO surrogate. Nor is EPA's "belief" that CO serves as an effective surrogate for POM sufficient. And finally, it is not enough to satisfy the requirement of §112(c)(6) to say, as EPA does, merely that because "the emissions tests obtained at currently operating units show that the proposed MACT regulations will reduce mercury emissions by about 86 percent," it is somehow "reasonable to assume that POM emissions will [also] be substantially controlled." 75 Fed. Reg. 32,042 (emphasis added).

CO is not a sufficient lawful surrogate for any organic HAP, including for POM or PCBs. And, while EPA agrees that "standards established under section 112(d)(2) must reflect the performance of MACT, 75 Fed. Reg. 32,008, there is no demonstrated correlation in the record for this proposal between levels of the CO surrogate and levels of emissions of POM, or PCBs emitted by ICIBPH. Nor is there any demonstration that the CO proposed floors will provide the equivalent health and environmental protection provided by a MACT floor standard if one were set for each of those pollutants. EPA therefore cannot "assure" through use of a surrogate that this listed industry's §112(c)(6) pollutant emissions are controlled to the level required by 112(d)(2) as it could if separate MACT floors were set, and compliance with those floors required, for those carcinogenic organics. Even if CO were a valid surrogate, though, on this record, § 112(c)(6) requires EPA to set § 112(d)(2) or (d)(4) standards with respect to POM and PCBs.

Comment: CO is not a lawful surrogate for any organic HAPs.

EPA says that it considered both total hydrocarbon (THC) and CO as surrogates, but chose CO because "CO has generally been used as a surrogate for organic HAP because CO is a good indicator of incomplete combustion and organic HAP are products of incomplete combustion." 75 Fed. Reg. 32,018. EPA correctly recognizes that this is not true for dioxin and furans, as these organic HAPs can be formed outside of the combustion unit, not as part of the combustion process, and so sets separate standards for these carcinogens. But for the remaining organic HAP, EPA simply states that "minimizing CO emissions will result in minimizing non-dioxin organic HAP. Methods for the control of [these HAP] would be the same methods used to control CO emissions. These emission control methods include achieving good combustion or using an oxidation catalyst." Id. EPA further asserts that "establishing emission limits for specific organic HAP (with the exception of D/F) would be impractical and costly." Id. None of these reasons is sufficient to support the selection of CO as a surrogate, over the requirement to set emissions standards for specific organic HAPs.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2746.1, excerpt 5.

Comment: EPA does not assert that organic HAP are "invariably present" when CO is present – only that CO indicates incomplete combustion and in those conditions the organic HAP are present. Second, while EPA says that "minimizing CO emissions will result in minimizing non-dioxin organic HAP," the agency does not assert in the preamble, and there is nothing in the record to indicate that this relationship is indiscriminate – i.e., that all the non-dioxin organics will always be minimized when CO are minimized. Indeed, EPA cannot make this assertion.

There are three classes of non-dioxin/furan organic HAPs that behave differently during combustion: (1) volatile organic compounds, which are gases; (2) semi-volatile organic compounds, which may be gases or solids, depending on where in the exhaust gas train they are; and (3) particulate organic compounds, such as polynuclear aromatic compounds, which are present in the particulate fraction. [See submittal for Reference 10.] A single indicator, CO, cannot be used as a surrogate for these three diverse groups of chemicals because they are chemically and physically dissimilar. Most of the particulate organic compounds for example, form primarily immediately downstream of the combustion chamber, as do dioxin/furans. This is far from the same mechanism by which CO is formed. Several of these compounds are not products of incomplete combustion, like CO, but rather are formed via distinct chemical reaction pathways. Polynuclear aromatic hydrocarbons are formed in condensation reactions, for example. [See submittal for Reference 11.]

Because of these diverse physical relationships, CO minimization or control does not indiscriminately minimize or capture non-dioxin/furan organic HAPs. Additionally sources can achieve lowered emissions of such organic HAP emissions by means other than CO control. For example, "combustion optimization" is a typical means that is used to control carbon monoxide. This includes changes in combustion residence time, turbulence, and temperature. Yet, combustion optimization can actually increase some organic HAPs (such as polynuclear aromatic hydrocarbons) while reducing others (such as VOCs). Other carbon monoxide controls, such as substituting alternative fuels (natural gas, or distillate oil), would reduce such organic HAPs at a far higher rate than methods for the limitation of carbon monoxide.

Response: Carbon monoxide is often used as an indicator of combustion conditions. Under conditions of ideal combustion, a carbon-based or hydrocarbon fuel will completely oxidize to produce only $CO2$ and water. Under conditions of incomplete or non-ideal combustion, a greater amount of CO will be formed. With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the production of CO would also limit the production of organics. As such, EPA is not including other options for compliance with respect to non-dioxin organic HAP; all units must meet CO limits.

Based on comments received there was insufficient data to determine if a lower threshold for CO exists. For example different thresholds were provided (100 vs 500 ppm). In the absence of specific data we computed the CO MACT floors using the data available. Also, since proposal many of the CO limits have increased, see the preamble for further discussion.

Regarding the use of oxidation catalysts to reduce organic HAP, there are permits for biomass units through the Florida Department of Environmental Protection which show organic HAP reductions via oxidation catalysts. See information for DEP File No. 0810226-001-AC.

Comment Excerpt Number: 16

Comment: Total hydrocarbons (THC) needs to be added as an alternative standard to CO as a surrogate for non-dioxin organic HAPs.

EPA has elected to propose CO as a surrogate for non-dioxin organic HAPs and is requiring CO CEMS for units larger than 100 mmBtu/hr. Compliance with the CO emission standard is then determined on a 30 operating day rolling average basis. While we have concerns that the MACT floor emission limitations do not properly account for load variation or periods of startups and shutdowns, we believe, that once the CO MACT floor level is properly determined, compliance with a CO limit will be the preferred method in many cases. However, Eastman requests that EPA set an alternative THC standard. The Hazardous Waste Combustor MACT (40 CFR 63 Subpart EEE) provides an option of a 100 ppm CO limit or a 10 ppm THC limit. While most hazardous waste incinerator operators selected the CO option, Eastman has selected the THC option at three of our incinerators and have found the THC CEMS, while more costly, to be a workable option.

Also, we have a case where THC may be much preferable to a CO limit. Eastman's largest and newest boiler is a wall-fired PC boiler which was installed with advanced combustion controls (low NOx burners and over-fire air system) to control NOx, plus a Spray Dryer Absorber (SDA) and Fabric Filter for control of acid gases. Preliminary CO CEMS data indicates this boiler will have difficulty attaining the proposed CO limit for PC boilers. Our experience with other solid fuel units shows us that THC levels are often more stable and less reactive to load swings than CO. Since THC really is a better indicator of non-dioxin organic HAPs that CO (CO is not a HAP whereas much of the THCs are HAPs), there is no reason EPA cannot grant our request and provide a THC option. Without the THC option, Eastman is likely to be faced with a very costly choice: either install a capital intensive CO catalytic reduction system; or remove the most modern and most effective combustion controls for NOx at this site to control CO, and install very expensive post-combustion NOx reduction technologies such as Selective Catalytic Reduction (SCR). Please note that industry experience advises against the use of less capital intensive NOx control technologies like Selective Non-Catalytic Reduction (SNCR) on units equipped with SDA's, due to the negative downstream effects of ammonia slip on personnel safety (NH_3 release in recycle slurry) and the reliability of downstream components (formation of fouling ammonium salts). Further note that either of these options will significantly increase system draft loss, which will likely require a new ID fan at considerable expense. Eastman does not believe that the enormous capital expense these options present are justified, given that such a solution reduces CO but may not actually reduce non-dioxin organic HAPs. Eastman believes that this is a classic case of unintended consequences with little commensurate benefit to health or the environment.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: EPA does not note these limitations on using CO as a surrogate for non-D/F organics. In fact, evidence from the test data show that EPA's testing protocols were designed from the beginning to test only for CO, not the organic HAPs for which it stands as a surrogate. Major Source ICR Testing Protocol Summary Supporting Statement at 7 (EPA-HQ-OAR-2002-0058- 0801. EPA therefore cannot show that CO and organic HAP are invariably present together and that minimizing or controlling CO always minimizes or controls all the organic HAP. Indeed, the results of those tests show that even for a single source, CO emissions differ radically from test to test – for the best performing coal-fired source for CO, EPA's data show: [See submittal for Table III-2 Data for EPA's Best-performing Coal Fired Source for CO.]

Comment: Third, and most notably, EPA does not assert that measures for the control of CO are the only means by which facilities 'achieve' lower emissions of non D/F organic HAP. Instead EPA relies on a cost-related argument to reject the idea of setting individual HAP-specific emissions limits for each of the non-D/F organic HAPs, noting that "CO, which is less expensive to test for and monitor, is appropriate for use as a surrogate," and that this is true despite the fact that "the level and distribution of organic HAP associated with CO emissions will vary from unit to unit." In other words, EPA cannot say, as it must to satisfy the Sierra Club test for the use of surrogates, that controls on or minimization of CO are the only method for controlling organic HAPs. EPA can only say, as it has, that relying on CO control as a surrogate for individualized MACT emissions limits for these HAPs will "eliminate costs associated with speciating numerous compounds." Id. EPA can't choose a surrogate just because it's cheaper. EPA must show that the surrogate actually meets the test for valid surrogates established by the D.C. Circuit. The agency has failed to do so here.

Comment: EPA clearly has failed to show that the CO surrogate meets the Sierra Club 3-part test for an effective surrogate for non-D/F organic HAPs. That deficiency might be cured if EPA in its background material or preamble provided a reasoned explanation , supported by substantial record evidence why using the CO surrogate otherwise will or can ensure that each of the organic HAPs that are emitted by various subcategories of ICIBPH will be controlled to the level of the relevant best performing sources, with respect to each of those HAPs. The Agency has not done so, however, and so its reliance on the CO surrogate is unreasonable.

Comment: In this proposal CO is established as a surrogate for organic HAP. Minimizing CO is, therefore, intended to demonstrate that organic HAP is minimized. It appears clear however that the level of organic HAP emissions becomes insensitive to CO concentration below some value (e.g., 100 ppm).
EPA itself has already reached this conclusion in the Hazardous Waste NESHAP rulemaking. As the Agency states at 70 FR 59462 (October 12, 2005):
We explained at proposal why the carbon monoxide standard of 100 ppmv and the hydrocarbon standard of 10 ppmv are appropriate floors. See 69 FR at 21282. The floor level for carbon monoxide of 100 ppmv is a currently enforceable Federal standard. Although some sources are achieving carbon monoxide levels below 100 ppmv, it is not appropriate to establish a lower floor level because carbon monoxide is a conservative surrogate for organic HAP. Organic HAP emissions may or may not be substantial at carbon monoxide levels greater than 100 ppmv, and are extremely low when sources operate under the good combustion conditions required to achieve carbon monoxide levels in the range of zero to 100 ppmv. (See also the discussion below regarding the progression of hydrocarbon oxidation to carbon dioxide and water). As such, lowering the carbon monoxide floor below 100 ppmv may not provide significant reductions in

organic HAP emissions. Moreover, it would be inappropriate to establish the floor blindly using a mathematical approach—the average emissions for the best performing sources—because the best performing sources may not be able to replicate their emission levels (and other sources may not be able to duplicate those emission levels) using the exact types of good combustion practices they used during the compliance test documented in our data base. This is because there are myriad factors that affect combustion efficiency and, subsequently, carbon monoxide emissions. Extremely low carbon monoxide emissions cannot be assured by controlling only one or two operating parameters.

AF&PA agrees that CO is an appropriate surrogate for organic HAP, but believe HAP emissions are minimized at levels well above the 1 or 2 ppm CO proposed for gas 2 and liquid boilers. As EPA concludes above, at CO levels below about 100 ppm, differences in organic HAP emissions are negligible. Where achievable emission limitations for organic HAP that properly reflect source category and unit variability are derivable from representative data, CO should continue to be used as the compliance surrogate for organic HAP. However, the CO limits should reflect the fact that the organic HAP concentration becomes insensitive to CO level below some value (e.g., 100 ppm).

Comment: The use of CO as a surrogate for the reduction of organic compounds is not new. For example, CO was used as an indicator of combustion efficiency as part of the Interim Status rule for Boilers and Industrial Furnaces (BIFs) that burn hazardous waste. At the time, EPA's research demonstrated that BIF units with CO emissions less than 100 ppmvd were achieving the desired destruction efficiency of the hazardous organics in the waste streams. As mentioned previously, because the chemical kinetics make CO far more difficult to oxidize than other organic compounds, it is not necessary to drive CO emissions to zero to obtain a corresponding minimization of organic emissions.
The data used to support the BIF Interim Status rule documented how the selected level of CO corresponded to minimal emissions of the target compounds. That should be the case for Boiler MACT as well. It is not logical to apply the same rules to establish a CO floor, when CO is merely the surrogate. It is more reasonable to collect data that demonstrate low organic emissions, and then to document the corresponding CO emissions for those sources.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Comment: Another aspect of CO emissions that make them a poor candidate for establishing a MACT floor as a surrogate for organic HAP is that CO emissions may vary significantly, without any adjustments being made to the boiler controls. For example, in a wood-fired boiler with a traveling grate, variations in the composition or moisture content of the wood may cause it to pile on the grate and smolder, leading to elevated CO emissions.

Response: See the preamble for discussion on how CO limits were modified.

Commenter Name: Timothy Hunt

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 186

Comment: Carbon monoxide is the most common product of incomplete combustion (PIC), and because of its associated chemical kinetics, is one of the most difficult PICs to oxidize completely. As such, CO emissions have historically been used as an indicator of the quality of the combustion process. The concept is that low CO emissions would equate to negligible emissions of other organic compounds. While this is true in general, the mechanisms by which CO is formed and destroyed in the combustion process are different than for other organics. As such, in cases where other organic compounds have been completely oxidized, CO concentrations may still be elevated. While the tendency is to think that further reductions in CO emissions will improve the quality of the combustion, and in turn minimize emissions of other organic compounds, this is not necessarily true. Instead, forcing CO emissions lower and lower ends up over-constraining the combustion process, producing negative impacts on other air quality concerns, without documented improvements in emissions of organics.

Comment: It is Appropriate to Use CO as a Surrogate but EPA did not Establish Achievable CO Emission Standards. We concur with the use of CO as a surrogate because establishing MACT limits for individual organic HAP would be impractical and costly. 75 Fed. Reg. at 32018. However, there are significant flaws regarding the CO limits that EPA proposes because they do not account for variation in CO emissions that can result from unit design and operation and which do not necessarily vary in proportion to organic HAP emissions. Because of this variation, it is essential that CO MACT limits be set at levels that can be met under all reasonably expected adverse conditions.

Response: See preamble for response to comments on how CO limits were modified.

Commenter Name: W. Randall Rawson
Commenter Affiliation: American Boiler Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2698.1
Comment Excerpt Number: 9

Comment: EPA has not adequately identified its basis for using CO as a surrogate for polycyclic organic matter ("POM"). ABMA acknowledges a correlation between CO and organic HAPs; however, ABMA is not aware of any relevant testing data that correlates the relationship between HAPs and CO when operating at CO levels less than 100 ppm. By contrast, data from the Petroleum Environmental Research Forum Project 92-19 provides some of the most complete data examining the relationship between CO and HAPs during gas firing. While there is a fairly linear correlation between decreasing CO and decreasing HAPs at higher levels, once the CO values fall under 100 ppm, further reduction of CO did not provide any substantial correlating reduction of HAPs. Based on this data, it can be concluded that during gas firing the reduction of CO from 100 ppm to 1 ppm may not create any incremental benefit in terms of HAP reductions. Without any data to the contrary, this relationship between CO and HAPs should also be applied to oil-firing, where EPA has not demonstrated that a significant HAP reduction would occur at CO levels below 100 ppm.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Commenter Name: Chris Greissing

Comment: Moreover, EPA has not done the analysis to establish a correlation between CO emissions and organic HAP emissions at all levels of CO. Although there may be a general directional correlation between the incomplete combustion products of CO and organic HAP, empirical data shows that reducing CO levels below 100 ppm does not result in appreciable further reductions in organic HAP. The CO MACT limits should reflect this fact, and further reductions in CO below 100 ppm should not be required because such reductions do not result in further HAP removal. The purpose of MACT limits is to reduce HAP, not to reduce CO for its own sake where there is no added benefit of further HAP reduction.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Comment: In this proposal CO is established as a surrogate for organic HAP. Minimizing CO is therefore, intended to demonstrate that organic HAP is minimized. We agree that CO is a good surrogate for organic HAQPs at higher CO levels, but it is clear that the level of organic HAP emissions becomes insensitive to CO concentration below some value, approximately 100 ppm for gas-fired units. Following is a general discussion of the relationship between CO concentration and organic HAP emissions. A specific review of the available data for gas, included as Attachment C, confirms the general discussion and finds that the data in the record indicate that there is no organic HAP benefit to setting a CO limit below 100 ppm.

EPA itself has already reached this conclusion in the Hazardous Waste NESHAP rulemaking, 70 FR 59462 (October 12, 2005):

Most organic hydrocarbons have a lower activation energy (in terms of combustion reactions) and will burn far better at much lower temperatures than CO will. You will see a massive amount of CO (> 500 ppmv) in your stack gases before you typically see significant uncombusted hydrocarbons.

CO is the most common product of incomplete combustion (PIC), and because of its associated chemical kinetics, is one of the most difficult PICs to oxidize completely. As such, CO emissions have historically been used as an indicator of the quality of the combustion process. The concept is that low CO emissions would equate to negligible emissions of other organic compounds. While this is true in general, the mechanisms by which CO is formed and destroyed in the combustion process are different than for other organics. As such, in cases where other organic compounds have been completely oxidized, CO concentrations may still be elevated. While the tendency is to think that further reductions in CO emissions will improve the quality of the combustion, and in turn minimize emissions of other organic compounds, this is not necessarily true. Instead, forcing CO emissions lower and lower ends up over-constraining the combustion process, producing negative impacts on other air quality concerns, without documented improvements in emissions of organics.

Comment: The use of CO as a surrogate for the reduction of organic compounds is not new, but previous rulemakings have concluded that it is only necessary to reduce CO to less than a particular level to minimize organic HAPs. For example, CO was used as an indicator of combustion efficiency as part of the Interim Status rule for Boilers and Industrial Furnaces (BIFs) that burn hazardous waste. At the time, EPA‘s research demonstrated that BIF units with CO emissions less than 100 ppmvd were achieving the desired destruction efficiency of the organic HAP in the waste streams. As mentioned previously, because the chemical kinetics makes CO far more difficult to oxidize than other organic compounds, it is not necessary to drive CO emissions to zero to obtain a corresponding minimization of organic emissions.

The data used to support the BIF Interim Status rule documented how the selected level of CO corresponded to minimal emissions of the target compounds. That should be the case for Boiler MACT as well. It is not logical to apply the same rules to establish a CO floor, when CO is merely the surrogate. It is more reasonable to collect data that demonstrate low organic emissions, and then to document the corresponding CO emissions for those sources.

API/NPRA agrees that CO is an appropriate surrogate for organic HAP, but believe HAP is minimized at levels well above the 1 or 2 ppm CO proposed. At CO levels below about 100 ppm, differences in organic HAP emissions are negligible.

Recommendation: Where achievable emission limitations for organic HAP that properly reflect source category and unit variability are derivable from representative data, CO should continue to be used as the compliance surrogate for organic HAP. However, the CO limits should reflect the fact that the organic HAP concentration becomes insensitive to CO level below some value (e.g., 100 ppm for gas-fired units).

Recommendation: If any CO emission limits are established for gas-fired units as a surrogate for organic HAP emissions, that limit should be no lower than 100 ppm.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Commenter Name: Matthew Todd and David Friedman

Comment Excerpt Number: 131

Comment: There is an additional problem with using CO as a surrogate for organic HAP at very low ppm levels. That is, levels of CO in combustion air going to the boiler or process heater are often higher than the proposed emission limit. Obviously, CO levels up to the CO level in the combustion air can have no relationship to organic HAP generation. It is certainly unreasonable to set a limit for a surrogate that is lower than the monitor would indicate if the equipment were not operating.

The CO National Ambient Air Quality Standard for CO is 9 ppm, 8-hour average and 35 ppm, 1-hour average. EPA reports current ambient levels to be well below these levels in most cases. [Footnote: See Chapter 3 of US EPS, Quantitative Risk and Exposure Assessment for Carbon Monoxide Amended, EPA-452/R-10-009, July 2010; Available at http://www.epa.gov/ttn/naaqs/standards/co/data/CO-REA-Amended-July2010.pdf] However, one hour levels often exceed the 1 and 2 ppm levels in this proposal and, sometimes significantly exceed those levels. Furthermore, vehicle exhaust is identified as the major source of CO and their presence at major sources could cause localized CO levels to exceed the levels in this proposal. In fact, review of EPA‘s 2008 data shows that only 10% of sites monitored have CO concentrations below 1 ppm during the annual second highest 8-hour period. This also means that during startups and shutdowns, when combustion air is passing through the unit uncombusted, at least 90% of units will exceed a 1 ppm emission limit.

While national averages do not reflect micro situations, the following graph shows that even on an 8 hour average basis the annual 2nd maximum 8-hour average on 206 sites is at or above the proposed CO limits. [Footnote: 2008 National Air Trend, CO air quality. http://www.epa.gov/airtrends/carbon.html#conat.]

[See submittal for graph of CO Air Quality, 1990-2008 (Based on Annual 2nd Maximum 8-hour Average) National Trend based on 206 Sites]

Thus, it is clear that levels of CO below about 5 ppm may be due to ambient CO and bear no relationship to organic HAP generation.

Recommendation: Account for ambient CO levels in considering the use of CO as a surrogate for organic HAP generation from boilers and process heaters.

Response: See the Preamble for discussion on how we addressed and revised CO limits.

Comment: CO as a surrogate for non-dioxin organics.
EPA chose CO as a surrogate for non-dioxin organic HAP. As EPA recognizes, CO has generally been used as a surrogate for organic HAP because CO is a good indicator of incomplete combustion and organic HAP are products of incomplete combustion. 75 FR 32018. EPA proposes to use emission control methods, including achieving good combustion or using an oxidation catalyst, that both control CO emissions and non-dioxin organic HAP. This correlation, though one step removed from the correlation between PM and HAP metals, is sufficiently strong to support use of CO as a surrogate. EPA need not quantify the correlation or assess the variability because the control technology—good combustion or using an oxidation catalyst—will always reduce some quantum of the non-dioxin organic HAP. Nat'l Lime, 233 F.3d at 639. Given this correlation, EPA is permitted to use CO as a surrogate for specific organic HAP because of the impracticality and cost of establishing emission limits for specific organic HAP. See Sierra Club, 353 F.3d at 986 (reasonable for EPA to use a surrogate "in light of the impracticability of setting individual standards for each metal"); Bluewater Network, 370 F.3d at 18 (use of hydrocarbons as surrogate for PM was reasonable where "direct regulation of PM is more difficult").

EPA's rationales for the use of each of these surrogates are in accord with the facts and the law on this issue. EPA has identified the HAP that it is attempting to regulate. Mossville Envt'l

Action Now v. EPA, 370 F.3d 1232, 1243 (D.C. Cir. 2005) (invalidating use of vinyl chloride as a surrogate where EPA did not identify the HAP for which it was serving as a surrogate). There is no legal barrier to using PM or any criteria pollutant as a surrogate for HAP in this context,. Nat'l Lime Ass'n, 233 F.3d at 638-39. EPA has established that these HAP invariably coexist with the surrogates and will be controlled to some extent by the same technology that controls the surrogate. See Nat'l Lime, 233 F.3d at 639. EPA need not make a numerical estimate of the correlation or discuss its variability. Id. Where alternative surrogates for or methods to control these HAP exist, EPA identified and discussed them. Sierra Club, 353 F.3d at 986. EPA has demonstrated the correlation between the HAP and the surrogates, clearly meeting the standard of reasonableness under National Lime and Sierra Club.

Response: EPA thanks the commenter for their input.

Comment: While CIBO agrees that CO is an appropriate surrogate for organic HAP, there are some issues that EPA should address. First, HAP emissions are minimized at levels well above the CO emission standard. In fact, at CO levels below 100 ppm, the differences in organic HAPs emitted are negligible. While high CO levels may imply organic HAP emissions, levels below 100 ppm likely do not have the same proportional level of HAP emissions. EPA should adjust the CO emission standard to reflect that the organic HAP concentration becomes insensitive to CO below certain levels. As discussed in other sections of these comments, forcing CO compliance increases NOx and wastes energy and it is not feasible to have an ultra low NOx burner and CO emissions of 1 ppm. EPA should incorporate a variability concept into the development of the CO standard so regulated sources can actually achieve it and also obtain the HAP reductions desired.

Furthermore, total hydrocarbons (THC) could be used as an alternative standard to CO as a surrogate for non-dioxin organic HAPs. While most hazardous waste incinerator operators will rely on the CO option, some sources may opt to select the THC option as THC CEMS, while more costly, are a workable option. THC levels are often more stable and less reactive to load swings than CO. Since THC is an indicator of non-dioxin organic HAPs (CO is not a HAP whereas much of the THCs are HAPs), there is no reason EPA cannot provide a THC option. Without the THC option, some sources are likely to be faced with a very costly choice: either install a capital intensive CO catalytic reduction system; or remove the most modern and most effective combustion controls for NOx to control CO, and install very expensive post-combustion NOx reduction technologies such as Selective Catalytic Reduction (SCR).

The use of less capital intensive NOx control technologies like Selective Non-Catalytic Reduction (SNCR) on units equipped with SDA's, due to the negative downstream effects of ammonia slip on personnel safety (NH3 release in recycle slurry) and the reliability of downstream components (formation of fouling ammonium salts). Further note that either of these options will significantly increase system draft loss, which will likely require a new ID fan at considerable expense. The enormous capital expense of these options present are not justified, given that such a solution reduces CO but may not actually reduce non-dioxin organic HAPs. This is a classic case of unintended consequences with little commensurate benefit to health or the environment.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: The combustion process converts fuels containing carbon and hydrogen to carbon dioxide and water via a chain of chemical reactions involving fuel components, combustion intermediates and oxidant (usually air). These reactions proceed at different rates depending on temperature and concentrations of species involved. In the furnaces of boilers and process heaters, these
reactions take place within a turbulent mixing process that brings fuel, oxidant, intermediates and products together in varying concentrations and at different temperatures. Equipment designers take great care to design their systems to achieve high combustion efficiency such as providing stable ignition, good fuel-air mixing and sufficient gas residence time at high temperatures within the furnace. Because of practical limitations of these processes in real combustion systems, trace amounts of the reactants and/or combustion intermediates may escape the furnace before the process is completed, resulting in trace amounts of CO, hydrocarbons and/or soot in the exhaust gas. These are undesirable not only because of pollutant implications but also because of fuel costs associated with incomplete conversion of chemical energy in the fuel to combustion products and useful heat or work.
CO and formaldehyde are natural combustion intermediates formed and consumed in flames. Methane (CH_4) is the major component of natural gas and most other gaseous fuels. When methane and air are introduced to the flame, the fuel reacts with oxygen and radical species that exist at high temperatures (O, OH, H) forming simpler hydrocarbons and hydrocarbon fragments such as methyl radical (CH3). CH3 oxidizes to formaldehyde (CH2O). Formaldehyde then converts to formyl radical (HCO), which then dissociates with oxygen to form CO as the last step in the combustion process before being oxidized to CO_2. Its formation late in the combustion process is one reason why CO is a good indicator of combustion efficiency it is formed after the hydrocarbons are consumed and itself is consumed in the coolest and oxygen-depleted portions of the flame. The reaction of CO with oxygen to form CO_2 also is a relatively slow one, making it a worst case indicator, and it is relatively easy to measure. A complete discussion of this subject can be found in any good combustion textbook.

The same hydrocarbon fragments formed as part of the normal combustion process can also be precursors to soot and O-HAPs such as benzene and polycyclic aromatic hydrocarbons (PAH). These are formed via complex pathways in fuel-rich pockets of the flame (e.g., Figures 1 and 2, from Marinov et al.). Most of the compounds formed are subsequently consumed, with only extremely trace amounts - parts per billion to parts per quadrillion surviving the combustion process.

Because CO formation arises from the same hydrocarbon precursors involved with O-HAP formation and its persistence as one of the final, slowest steps in the combustion process, these characteristics make it an ideal indicator of O-HAP emissions.

Response: EPA thanks the commenter for their input.

Comment: CO, total hydrocarbons (THC) and formaldehyde emissions data for gaseous fuels were collected by EPA during the 2008-2009 Boiler MACT Information Collection Request process. These data represent many different types and configurations of boilers, process heaters and metal furnaces. Variations among designs may include heat input capacity, furnace gas temperature and residence time, number and type of individual burners, NOX emission control equipment, operating load and excess O2 during the tests, state of combustion tuning, and others. Although THC is not an O-HAP per se, it may include O-HAPs. Since hydrocarbons are an essential precursor to aldehydes, aromatic and polycyclic O-HAPs, it therefore may be considered a conservative indication of O-HAP potential. The data show that THC and formaldehyde concentrations are consistently at near-zero levels when CO is below 100 ppm (Figure 3).
Above this level, both THC and formaldehyde begin to rise significantly.
To examine the impact of different CO thresholds on THC emissions, the mean THC concentration and 95% confidence intervals were calculated for CO thresholds of 1, 10 and 100 ppm (Figure 4). The THC data for all gas-fired subcategories were grouped together, a total data population of 75 points with CO concentration of 100 ppm and lower. Mean THC emissions are the same (1.6 ppm) for CO thresholds of 1 ppm (54 data points) and 10 ppm (62 data points) and the 95% confidence intervals are approximately the same also. The mean THC concentration (2.7 ppm) is slightly higher at a CO threshold of 100 ppm, and the variability as indicated by the confidence intervals is slightly greater. The overlap of confidence intervals for each threshold shows that the means are not significantly different at the 95% confidence level.
It should be noted that 2 data points with THC concentration far higher than the other data in this region are clearly outliers, seen in Figure 3 for Gas 1 M at CO concentrations of approximately 30 ppm and THC levels of 370-400 ppm. These results are for a natural gas-fired aluminum preheating furnace, and the elevated THC concentrations correspond to test runs performed at

times during the latter part of the batch cycle where the burners operate at very low load. While not unusual for metal furnaces, this operational duty cycle is not typical of most other types of indirect-fired boilers and process heaters; therefore these two data points were excluded from the analysis.

Similarly, the mean formaldehyde concentration and 95% confidence intervals were calculated (Figure 5). The formaldehyde data were aggregated for all gas fuel subcategories as noted above. The mean formaldehyde concentrations are approximately the same, between approximately 0.1 and 0.3 ppm, for CO upper limits from 1 to 100 ppm. Overlap of the confidence intervals indicates that the slight variation in mean formaldehyde concentration is not significant at the 95% confidence level.

Combustion fundamentals indicate that CO should be a conservative surrogate for O-HAP emissions. Pilot scale and previous field test results show that gas combustion within the normal range of operating conditions is expected to produce O-HAP emissions below or near measurement detection limits. At extreme failure mode conditions, elevated emissions of both CO and O-HAPs were evident. The emission test data collected by EPA from a wide variety of boilers, process heaters and metal furnaces clearly show that low CO concentration is consistent with low THC and formaldehyde concentrations. The field data show that THC and formaldehyde emissions insensitive to CO concentrations below approximately 100 ppm. At higher CO levels, THC and formaldehyde also tend to be higher and more variable among different units tested. Data for non-metal furnaces firing both Gas 1 and Gas 2 subcategory fuels are very consistent in this regard.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: The ICR data discussed above includes a wide range of equipment designs and operating conditions. O-HAPs from gas combustion were studied in a collaborative government-industry program in a pilot-scale combustion facility at Sandia National Laboratories in Livermore, California (Seebold, 1997; England et al., 2001). The pilot-scale combustor was configured with a single, up-fired low-NOX gas burner typical of those installed on thousands of indirect-fired process heaters used in petroleum refining and petrochemical production. The burner was a staged combustion design, with “primary” and “secondary” combustion zones. Concentrations of O-HAPs aldehydes, PAH, VOCs were measured for each test condition. A total of 55 different test conditions were evaluated. Tests were conducted over a range of furnace temperatures, fuel compositions and air-fuel settings considered representative of the normal range of full-scale field operating conditions. O-HAP concentrations are generally at or near method detection limits under these conditions (Figure 6).

A series of test under conditions far outside of the normal range also were conducted to evaluate potential failure modes leading to elevated emissions, such as excessive air or fuel in the primary and/or secondary zones, mechanical failure of the burner, and other conditions that would not be encountered in properly operated and maintained field systems but which may occur due to equipment or control failure. O-HAP concentrations are generally similar to those during normal operating conditions, except for cases of extreme air starvation or extreme air quench (Figure 7). Under fuel rich failure modes (total overall stoichiometric ratio, SRt, less than 1), concentrations of aromatic ring compounds (e.g. benzene) and polycyclic hydrocarbons (e.g. PAH) rise sharply. These conditions are also characterized by visible black smoke (smoke spot measurement). This is consistent with the chemistry mechanisms shown in Figures 1 and 2. Under very fuel lean failure modes (excess air 200% and higher), formaldehyde rises sharply accompanied by a modest rise in aromatic and polycyclic compounds. This is consistent with breakdown of the hydrocarbon and CO oxidation chain due to low combustion temperatures and ignition instability.

The relationship between THC and CO during failure mode tests also shows two modes depending on the distribution and range of air-fuel ratios (Figure 8). Elevated THC levels during fuel rich failure modes are also accompanied by very high CO levels. Elevated THC levels during fuel-lean failure modes are accompanied by more modest CO levels. The data suggest different CO intercepts associated with each failure mode. For fuel-rich failure modes, log-log extrapolation of the data to zero THC suggests the onset of THC would occur when CO concentration reaches somewhere in the range of 1000‘s of ppm. For fuel-lean failure modes, the onset of THC formation appears to occur when CO reaches concentrations in the range of 10‘s of ppm.

Aldehydes also show a different relationship with CO depending on failure mode (Figure 9). For fuel-lean failure modes, elevated aldehyde concentrations are accompanied by high CO levels. For fuel-rich failure modes, aldehyde formation is minimal or zero over a wide range of CO. This also is consistent with combustion chemistry fundamentals.

These pilot-scale results illustrate the usefulness of CO as a surrogate indicator for HAP emissions. Elevated HAP emissions are accompanied by elevated CO under fuel-rich and fuel-lean failure modes. However, elevated CO emissions at modest levels do not always produce elevated HAP emissions, suggesting that a modest threshold for CO

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Commenter Name: Catharine Fitzsimons

Comment Excerpt Number: 1

Comment: IDNR has the following questions for which it requests that EPA consider and include in its response to comments when finalizing this proposed rule:

1) What test data does EPA have that demonstrates the relationship between CO and non-dioxin organic HAP emissions?
2) If a facility installs add-on emissions controls (e.g. catalytic oxidation), what data does EPA have that shows that there will be a reduction in non-dioxin HAP emissions?
3) In the case of coal-fired boilers, many facilities are installing SO2 controls such as dry scrubbers. These controls can provide some reduction of non-organic HAP emissions. What data does EPA have showing there is still a correlation between CO and non-dioxin organic HAP emissions in these cases?

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15.

Commenter Name: Catharine Fitzsimons
Commenter Affiliation: Iowa Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-2767.1
Comment Excerpt Number: 2

Comment: If EPA does not wish to conduct testing to establish this correlation in development of the final Boiler MACT, IDNR recommends that EPA 1) Establish specific standards for specific, organic HAP; 2) Allow the source the option of conducting performance testing for these specific HAP; and 3) Allow the source the option to establish a CO emission level consistent with meeting the standard for the organic HAP.

Response: EPA is not providing alternative compliance options and boilers must meet the applicable CO limits.

Commenter Name: H. Allen Faulkner
Commenter Affiliation: Ascend Performance Materials, LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2743.1
Comment Excerpt Number: 2

Comment: Ascend has a specific comment on item 8d -the CO limit for units designed to burn liquid fuel. The proposed rule has a CO limit of I ppm by volume on a dry basis corrected to 3 percent oxygen. The Decatur site currently operates two process heaters that have a rated heat input capacity of 30 million Btu per hour and would be required to meet this limit based on a 3-run stack sampling,

Ascend requests that EPA reconsider the limit of I ppm. Ascend recognizes that EPA has established this limit as a surrogate for organic HAP emissions and that CO is a good indicator of complete combustion. However, Ascend believes that complete combustion and reductions in organic HAP emissions can be met at much higher CO levels. In fact, EPA reached the same conclusion during the Hazardous Waste NESHAP rulemaking in 2005, where they stated that lowering CO limits below 100 ppmv may not provide significant reductions in organic HAP destruction. Ascend requests that EPA consider modifying the CO limit to a more reasonable concentration, such as 100 ppm CO.

Response: See the preamble for discussion of the revised CO limits.

Commenter Name: Sonnichsen Engineering, LLC
Commenter Affiliation: Tim W. Sonnichsen
Document Control Number: EPA-HQ-OAR-2002-0058-2931.1
Comment Excerpt Number: 3

Comment: The EPA presumes that carbon monoxide (CO) is an appropriate surrogate for other hydrocarbon HAP's. Page 24 of the Area Rule states "A high level of CO is an indicator of incomplete combustion and, thus, a potential indication of elevated organic HAP emissions." The key words in this sentence are "high" and "potential."

If high levels of CO are and indicator of organic HAP's, then the proposed practice of minimizing CO levels to very low levels does not necessarily mean that organic HAP's emissions would be any lower than what would occur at higher CO emission levels. EPA only refers to the potential relationship of CO to organic HAP's. Obviously, there is not a one-to-one correlation of decreasing HAP's with decreasing CO. Would not a more reasonable CO limit based on actual data be preferred rather than the proposed approach of minimizing CO to the maximum level "achievable"?

An example: The State of Wisconsin has for many years imposed a maximum CO level of 500 ppm on industrial-sized wood-fired boilers operating in its state. It has been determined by the state that this CO emission limit will effectively eliminate formaldehyde and other organic HAP's emissions. Would imposing a lower CO limit effectively reduce these emissions? Evidently not according to the State of Wisconsin.

Therefore, imposing absurdly low CO emission levels would likely have no significant benefit to the public by reducing the exposure to organic HAP's while requiring the boiler owner to install expensive and likely unattainable CO emission control requirements

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Document Control Number: EPA-HQ-OAR-2002-0058-2785.1

Comment Excerpt Number: 5

Comment: Organic HAP Surrogate: The Proposed Rule relies on Carbon Monoxide emissions as a surrogate for organic HAP emissions. While this may seem to be a logical and simplified approach, there is no testing data or proof that this surrogate is an appropriate approach to establishing a MACT Standard. Further, using the Carbon Monoxide emissions from historical stack test results solely as the data to establish the MACT Floor for Organic HAP emissions is inappropriate.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 6

Comment: For this rule, MidAmerican does not support the use of CO as a surrogate for organic HAPs for all affected units and fuel types. MidAmerican concedes EPA's assertion that CO emissions are easier and less expensive to measure and monitor than to measure and monitor emissions of each individual organic HAP, and that they behave similarly as products of poor combustion. However, in this proposed rule, the EPA assumes a 1:1 production and control ratio of CO to organic HAPs; however, there is limited data for certain fuels and size subcategories to demonstrate that there is a strong correlation with CO and organic HAPs at lower limits. The few tests that have been conducted have demonstrated that it is difficult to correlate CO with organic HAPs when CO concentrations fall below 100 parts per million ("ppm"). In this proposed rule, EPA is setting CO emission limits well below 100 ppm. In the case of new and existing gas and liquid units the EPA has set the CO limit at 1 ppm.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Commenter Name: Marvis A. Lewallen
Commenter Affiliation: Clearwater Paper
Document Control Number: EPA-HQ-OAR-2002-0058-2862
Comment Excerpt Number: 7

Comment: EPA has established CO as the sole surrogate for organic HAPs. However, many of the organic HAPs are not well represented through use of CO as a surrogate. This is particularly true in this industry sector where many boilers are seeking to reduce NOx emissions and so have tuned their boilers such that CO emissions are preferred over NOx. Ironically, this approach has been driven by other EPA mandates. By requiring the use of CO as the surrogate for organic HAPs, EPA would require these sources to alter combustion practices to now increase NOx emissions. In addition, many of the organic HAPs that are derived from biomass are readily destroyed at the high combustion zone and exhaust temperatures typical of biomass boilers. Carbon monoxide, however, has a much higher auto-ignition temperature than the predominant HAPs from biomass. As a result, CO is not a good surrogate across the range of operations typical of a biomass boiler and it is not a good surrogate for the efficacy of any control methods. For all of these reasons, we request that EPA provide alternatives to CO as the basis for HAP control, much as the agency did in the PCWP MACT rulemaking.

Response: See the preamble for discussion of the revised CO limits.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 7

Comment: Instead of using CO as a surrogate for organic HAPs and establishing very stringent emission limits for both new and existing sources, MidAmerican believes that the most effective and efficient means to control organic HAPs is through the control of the actual combustion process. Both CO and organic HAPs are good indicators of incomplete combustion. Therefore, EPA could promote combustion optimization to reduce organic HAPs. Combustion optimization will be specific to the type of boiler and actual fuel characteristics. Individual facilities should be allowed the flexibility to determine the appropriate level of combustion optimization that will minimize emissions of organic HAPs. Actual combustion optimization could include burner tuning but should not require annual unit outages. The final Boiler MACT should allow facilities to implement actual Work Practice Standards to optimize combustion instead of complying with the proposed stringent CO emission limits. The proposed Work Practice Standards could be expanded to include specific classes of boilers and process heaters with a capacity over 10 million Btu per hour.

Response: See the preamble for discussion on setting MACT standards and how CO limits were modified.

Commenter Name: Jeffrey R.Klieve
Commenter Affiliation: Monsanta Company
Document Control Number: EPA-HQ-OAR-2002-0058-2754.1
Comment Excerpt Number: 9

Comment: Presuming that CO concentration is an indicator parameter for combustion efficiency for organic HAPs present in a fuel stream, these Gas 2 requirements are irrelevant to the control of HAP emissions from Monsanto’s H2 fuel stream. Thus the excessive cost of complying with these requirements is unwarranted.

Response: Subcategory definitions have been revised, see the preamble for discussion.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 10

Comment: Carbon monoxide (CO) is a product of incomplete combustion, as are many volatile organic HAPs and semi-volatile organic HAPs. While these chemicals are all products of inefficient combustion, Southern Company does not believe that CO is not an adequate surrogate for organic HAPs, particularly for liquid and solid fuels.

Combustion of fuels for industrial boilers follow the general mixing pattern of many furnaces for combustion, that is, a highly mixed zone of visible flames typically followed by a longer zone of much less mixing. For example, the furnace area of the burner or burners of a typical coal-fired industrial boiler is where the greatest degree of mixing occurs, and is normally followed by a path where the individual burner streams merge and slowly pass through the top sections of the furnace and over convective steam tubes. In reactor engineering terms, industrial combustion can typically be modeled by a constantly-stirred reactor (CSTR) for the burner zone immediately followed by a plug-flow reactor (PFR) for the furnace zone above the burners through the convective section.

For complete combustion, the combustible material that survives the burner zone will have another opportunity to be consumed in the plug-flow zone. Combustion ordinarily requires several things to occur: time for the combustion reaction to complete, high enough temperature to sustain the combustion reactions, enough oxidizer (oxygen, O2, from the combustion air) left over to react with the combustible compounds, and enough mixing to bring the oxidizer and the combustible compounds together.

While it may be true in some circumstances that CO emissions and organic emissions will trend with each other, the differences in the formation and destruction mechanisms during combustion between CO and these other compounds makes CO a very imprecise surrogate. In solid fuel combustion, CO is a major intermediate and thousands of ppm CO are normally found in these flames before being destroyed in the later combustion process. CO is normally formed by the combustion of volatile compounds produced by fuel heating, the combustion of solid char particles, and also by oxidation of soot formed in the flame. Furthermore, the equilibrium between carbon dioxide (CO_2) and CO tends towards more CO as the temperature increases. Therefore, increasing furnace temperatures can produce more CO in the flame just from the chemical equilibrium. Lawn states [Footnote: Principles of Combustion Engineering for Boilers, edited by Lawn, C.J., Academic Press, London, 1987.]

In the presence of excess oxygen the equilibrium concentration of CO at low temperatures is negligible. However, at peak flame temperatures the equilibrium

CO_2 = CO + 0.502

is shifted to favour [sic] CO so that, even under stoichiometric conditions, there is some 3000 vpm of CO in oil firing.

Polycyclic aromatic hydrocarbons (PAH) can be produced and destroyed by a number of mechanisms. These compounds can be formed in secondary devolatilization products in coal, oil, and biomass combustion, but also can then disappear by condensing into soot. PAH can also be formed from the condensation of lighter hydrocarbons in low oxygen regions of the flame. PAH would normally also be destroyed by the combustion of these compounds given enough time, temperature, oxygen, and mixing. The complicated nature of the production and destruction of CO and other hydrocarbons in flames makes the results of experimental tests important in trying to understand the behavior of each.

One important experimental study was conducted by Levendis and Atal from Northeastern University along with Carlson of the U.S. Army [Footnote: Levendis, Y. A., Atal, A., Carlson, J. B., "On the correlation of CO and PAH emissions from the combustion of pulverized coal and waste tires," Environ. Sci. Technol., 32:3767-77 (1998).] These experimenters combusted coal and tire-derived fuel in a well-controlled drop-tube furnace and measured a number of organic emissions as well as CO. They found

At fixed bulk equivalence ratios [excess air levels], however, as the furnace gas temperature increased the PAH yields from both fuels decreased drastically, while the CO yields increased.

They were not able to clearly distinguish why the CO levels increased at the higher furnace temperatures, however. Because furnace temperatures will change with load, with slagging and fouling behavior, with different coals, and even with annual seasons, any correlation between CO and the organic compounds is dependent on always having the same combustion temperature – which is unrealistic. The authors also summarize by saying

Thus, at elevated furnace temperatures, high CO partial pressures may give a false warning on the PAH emissions.

This result is a major reason why Southern Company believes that CO is not a surrogate for the other organic compounds. One or more of the routes of formation and/or destruction of CO versus other organics must act differently when the flame temperature goes up, thus producing more CO emissions but lower organic levels. With such a dramatic difference in emissions resulting from a simple change in temperature, CO is clearly not a good choice for a surrogate for other organic compounds across the spectrum of fuels, boilers, and operating conditions covered by this proposed regulation.

Our recommendation is that a single organic compound, like benzene or toluene, be used as a surrogate, with annual stack testing used for compliance. There are no instruments capable of measuring such low amounts of these compounds continuously in flue gas at present. (Formaldehyde might be a good surrogate as well, but the measurement issues of sampling for formaldehyde in flue gas by manual stack testing methods are so great at present as to make this choice unworkable.)

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15.

Commenter Affiliation: Institute of Clean Air Companies
Document Control Number: EPA-HQ-OAR-2002-0058-2937.1
Comment Excerpt Number: 30

Comment: Using CO as a surrogate does not assure reduction of organic HAP since the two are not always directly related. Optimizing boiler operation for CO is a convenient method for improving efficiency, but it does not assure any level of HAP reduction. It is preferred that the regulations require testing for total hydrocarbon; this method is no more cumbersome or expensive to conduct on a periodic basis than measuring for CO.

One example of the disconnect between CO and HAP emissions is the impact that most SCR catalysts have on dioxin removal. SCR catalysts can remove 90%+ of dioxins, and this has no relation to the amount of CO in the gas stream or the low level of reduction of CO by the SCR catalyst. Likewise there are base metal (non–PGM) catalysts that will destroy certain types of HAPs without reducing the CO. Synthesis of PCDD/F downstream of the boiler is a recognized source of HAPs in the stack. There is no simple correlation between the CO and the PCDD/F formation.

The preferred method would be to measure total hydrocarbons which can be easily measured using a total hydrocarbon analyzer at periodic intervals. A boiler operator can conduct a THC test just as easily as a CO test. Then a map of the VOC versus CO emissions can be determined for each boiler type and burner configuration. Once the optimum level of HAP is identified, the boiler set points of load and excess O2 can be determined. The boiler operator would simply need to operate the boiler at these operating conditions and demonstrate compliance by maintaining operating records routinely recorded in data capture systems. This is analogous to the already accepted control philosophy for controlling VOC from regenerative thermal oxidizers. The operator must maintain a combustion zone temperature at a prescribed level that provides reasonable assurance of continuous compliance.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: Once a boiler operator decides that additional CO control is required, the stack CO level is no longer tied to burner operation, and may not relate to HAP emissions. A burner can be allowed to emit much larger amounts of CO since the catalyst will control it downstream. This could encourage higher CO boiler levels (and higher HAP emissions), negating the intended effect.

Removing CO by means of a catalyst may not result in improved HAP control, which depends on the type of HAP and the temperature at which the catalyst is operated. Most industrial boilers will have a CO catalyst installed at the boiler exit, and that temperature is sufficient to control CO but will not control any organic HAP. CO lights off on a catalyst at much lower temperatures than do most HAP’s, as shown in Table 4. See submittal for table 4 showing that neither Toluene nor Benzene will be controlled at low temperatures. So, once a catalyst is installed, the boiler operator has many ways to operate the boiler that could actually increase HAP.

Response: Regarding the use of oxidation catalysts to reduce organic HAP, there are permits for biomass units through the Florida Department of Environmental Protection which show organic HAP reductions via oxidation catalysts. See information for DEP File No. 0810226-001-AC.

Comment: A boiler operator can control organic HAP with the addition of activated carbon used for controlling mercury. However, the CO is not controlled and the boiler operator now must add additional control measures to control CO even though organic HAP is under control. For these reasons it is much more prudent to measure total hydrocarbons directly, rather than relying on a CO measurement.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: Direct measurement of total hydrocarbons using the following technologies; catalytic, photo-ionization, infra-red, gas chromatography and flame ionization is possible. ICAC strongly recommends that, as opposed to CO, that Total Hydrocarbons (THC) be measured as the basis for a surrogate for carbon-based HAPS. A number of technologies are available for THC measurements including Flame Ionization Detectors FIDs, Fourier Transform InfraRed, etc.

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: One provision of the proposed boiler MACT that is of concern in regard to increasing NOx emissions is the use of carbon monoxide (CO) as the surrogate for HAPs. If CO compliance limits for combustion sources are set too low, the result may be increased NOx emissions. One option for an alternative to CO exclusively is to look at boiler efficiency as a surrogate for organic HAPs. The concept here is to use continuous, parametric monitoring of combustion efficiency in addition to CO continuous emission monitors (CEMs) as the control for HAPs.

As an example it may be possible to measure the combustion efficiency for a specific type of boiler firing a specific type of fuel using ASME methods (e.g., Heat-Loss and/or Input-Output boiler efficiency calculations from the ASME test forms) to see if a minimum efficiency standard could be determined for the boiler. That minimum combustion efficiency limit could then be used in addition to using CO limits as a surrogate for good combustion control for HAPs. Some examples of existing boiler efficiency test procedures are referred to in the following documents, which are provided in the submittal of these comments: Cleaver Brooks boiler fact sheet, Partners in Innovation Project document and NISTIR 6913 AHRAE Standard 103-1993.

Response: See the Preamble for discussion of the relationship between CO and Nox and how we addressed and revised CO limits.

Comment Excerpt Number: 3

Comment: 63.7510(c): The use of CO as a surrogate for HAP emissions may not be accurate particularly for sources that are also acting as control devices for other MACT sources. Significant HAP/VOC destruction may be seen, however, the CO levels may not meet the levels as indicated by the “Boiler MACT”. Even with a total VOC destruction efficiency greater than 99%, the CO levels may not meet the levels specific in this standard and by monitoring the CO, would not reflect the actual efficiency of the unit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15.

Comment: EPA proposes to use carbon monoxide (CO) emissions as an indicator of the quality of the combustion process on grounds that low CO emissions would equate to negligible emissions of other organic compounds. Although this is true in general, the mechanism by which CO is formed and destroyed in the combustion process differs from other organics, and CO concentrations may remain elevated long after other organic compounds have been completely oxidized depending on the firebox configuration. By forcing lower and lower CO emissions, EPA may over-constrain the combustion process; thereby resulting in the negative impacts on air quality without any measurable improvements in emissions of organic HAPs. EPA should reconsider its categorization, to avoid over-constraining the combustion process with its CO limits.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Comment: Carbon monoxide is not an appropriate surrogate for organic HAP emissions . While carbon monoxide is a product of incomplete combustion and is an organic compound that can be analyzed and readily measured with CEMS, it is not an appropriate surrogate for organic HAP emissions from biomass combustion. Carbon monoxide has an auto-ignition temperature of almost 1,200°F and manufacturers of thermal oxidizers will tell you that carbon monoxide control efficiency drops off significantly below 1,600°F. Typical organic HAPs from incomplete biomass combustion and their auto-ignition temperatures include: methanol (878°F), formaldehyde (806°F), propionaldehyde (404°F), and acetaldehyde (347°F), all of which are much more easily controlled. The burden to control CO rather than the expected organic HAPs is excessive. A more appropriate surrogate would be total hydrocarbons (THC).

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: EPA has established CO as the sole surrogate for organic HAP. However, many of the organic HAPs are not well represented through use of CO as a surrogate. This is particularly true in this industry sector where many boilers are seeking to reduce NOx emissions and so have tuned their boilers such that CO emissions are preferred over NOx. Ironically, this approach has been driven by other EPA mandates. By requiring the use of CO as the surrogate for organic HAPs, EPA would require these sources to alter combustion practices to now increase NOx emissions. In addition, many of the organic HAPs that are derived from biomass are readily destroyed at the high combustion zone and exhaust temperatures typical of biomass boilers. Carbon monoxide, however, has a much higher auto-ignition temperature than the predominant HAPs from biomass. As a result, CO is not a good surrogate across the range of operations typical of a biomass boiler and it is not a good surrogate for the efficacy of any control methods. For all of these reasons, we request that EPA provide alternatives to CO as the basis for HAP control, much as the agency did in the PCWP MACT rulemaking.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15 and the preamble for additional discussion on CO limits.

Comment: While it may not be possible to reduce CO emissions sufficiently through combustion controls, it may be possible to adequately reduce organic HAPs through combustion modifications because of their lower ignition temperatures. Roseburg Forest Products believes that facilities should be given the option to demonstrate through testing that their organic HAP emission levels are sufficiently low to protect human health and the environment. An organic HAP emission limit would make more sense than a criteria pollutant emission limit. CO emissions could be measured and correlated to these test results so that a facility-specific CO emission rate can be established at which adequate control of organic HAPs is taking place. If CO emissions are utilized in this way, Roseburg Forest Products believes that CO may be an adequate surrogate for organic HAP emissions.

Response: EPA is not providing an option to determine site-specific limits and must meet the CO limits for a boiler's subcategory.

Commenter Name: Roy W. Wood
Commenter Affiliation: Eastman Kodak Company
Document Control Number: EPA-HQ-OAR-2002-0058-2917.1
Comment Excerpt Number: 11

Comment: Coal is a mixture of many different organic compounds that may be HAPs or have the potential to form HAPs if not burned completely. Natural gas is essentially composed of methane, which is not a HAP and has little potential to form HAPs during combustion. Kodak uses NOx reburn in three of its coal-fired boilers to reduce NOx emissions levels. NOx reburn is a technology used to reduce NOx formation by routing the coal-fired combustion gases through a fuel-rich, oxygen-starved, high temperature zone created by substoichiometric natural gas combustion. The NOx is converted to N2 and O2 in the reburn zone. CO is created from the natural gas combustion due to the low oxygen availability. The majority of the CO is converted to CO_2 in the burnout zone created by adding additional oxygen. This technology results in higher CO and substantially lower NOx, but likely does not increase the formation of organic HAPs. Therefore the organic HAP/CO ratio for a NOx reburn source is expected to be substantially lower than for other coal-fired sources. Therefore sources with low HAP/CO ratios should have alternate
compliance options, such as setting a CO level based on passing an organic HAP emissions test or using an alternate surrogate such as total hydrocarbons. The total hydrocarbon approach is used in the hazardous waste incinerator MACT (63.1219(a)(5)).

Response: EPA thanks the commenter for their input, but EPA's Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. See preamble for response to comments on how CO limits were modified.

Comment: In this proposal CO is established as a surrogate for organic HAP. Minimizing CO is, therefore, intended to demonstrate that organic HAP is minimized. It appears clear however that the level of organic HAP emissions becomes insensitive to insensitive to CO concentration below some value, approximately 100 ppm for gas-fired units. Following is a general discussion of the relationship between CO concentration and organic HAP emissions. EPA itself has already reached this conclusion in the Hazardous Waste NESHAP rulemaking. As the Agency states at 70 FR 59462 (October 12, 2005):

We explained at proposal why the carbon monoxide standard of 100 ppmv and the hydrocarbon standard of 10 ppmv are appropriate floors. See 69 FR at 21282. The floor level for carbon monoxide of 100 ppmv is a currently enforceable Federal standard. Although some sources are achieving carbon monoxide levels below 100 ppmv, it is not appropriate to establish a lower floor level because carbon monoxide is a conservative surrogate for organic HAP. Organic HAP emissions may or may not be substantial at carbon monoxide levels greater than 100 ppmv, and are extremely low when sources operate under the good combustion conditions required to achieve carbon monoxide levels in the range of zero to 100 ppmv.141 (See also the discussion below regarding the progression of hydrocarbon oxidation to carbon dioxide and water). As such, lowering the carbon monoxide floor below 100 ppmv may not provide significant reductions in organic HAP emissions. Moreover, it would be inappropriate to establish the floor blindly using a mathematical approach—the average emissions for the best performing sources—because the best performing sources may not be able to replicate their emission levels (and other sources may not be able to duplicate those emission levels) using the exact types of good combustion practices they used during the compliance test documented in our data base. This is because there are myriad factors that affect combustion efficiency and, subsequently, carbon monoxide emissions. Extremely low carbon monoxide emissions cannot be assured by controlling only one or two operating parameters.

The use of CO as a surrogate for the reduction of organic compounds is not new, but previous rulemakings have concluded that it is only necessary to reduce CO to less than a particular level to minimize organic HAPs. For example, CO was used as an indicator of combustion efficiency as part of the Interim Status rule for Boilers and Industrial Furnaces (BIFs) that burn hazardous waste. At the time, EPA's research demonstrated that BIF units with CO emissions less than 100 ppmvd were achieving the desired destruction efficiency of the organic HAP in the waste streams. As mentioned previously, because the chemical kinetics make CO far more difficult to oxidize than other organic compounds, it is not necessary to drive CO emissions to zero to obtain a corresponding minimization of organic emissions.

The data used to support the BIF Interim Status rule documented how the selected level of CO corresponded to minimal emissions of the target compounds. That should be the case for Boiler MACT as well. It is not logical to apply the same rules to establish a CO floor, when CO is merely the surrogate. It is more reasonable to collect data that demonstrate low organic emissions, and then to document the corresponding CO emissions for those sources.

Commenter Affiliation: Rubber Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 22

Comment: EPA chose CO as a surrogate for non-dioxin organic HAP. As EPA recognizes, CO has generally been used as a surrogate for organic HAP because CO is a good indicator of incomplete combustion and organic HAP are products of incomplete combustion. 75 Fed.Reg. at 32,018. EPA proposes to use emission control methods, including achieving good combustion or using an oxidation catalyst, that both control CO emissions and non-dioxin organic HAP. This correlation, though one step removed from the correlation between PM and HAP metals, is sufficiently strong to support use of CO as a surrogate. EPA need not quantify the correlation or assess the variability because the control technology—good combustion or using an oxidation catalyst—will always reduce some quantum of the non-dioxin organic HAP. Nat'l Lime, 233 F.3d at 639. Given this correlation, EPA is permitted to use CO as a surrogate for specific organic HAP because of the impracticality and cost of establishing emission limits for specific organic HAP. See Sierra Club, 353 F.3d at 986 (reasonable for EPA to use a surrogate "in light of the impracticability of setting individual standards for each metal"); Bluewater Network, 370 F.3d at 18 (use of hydrocarbons as surrogate for PM was reasonable where "direct regulation of PM is more difficult").

EPA's rationales for the use of each of these surrogates are in accord with the facts and the law on this issue. EPA has identified the HAP that it is attempting to regulate. Mossville Envt'l Action Now v. EPA, 370 F.3d 1232, 1243 (D.C. Cir. 2005) (invalidating use of vinyl chloride as a surrogate where EPA did not identify the HAP for which it was serving as a surrogate). There is no legal barrier to using PM or any criteria pollutant as a surrogate for HAP in this context,.Nat'l Lime Ass'n, 233 F.3d at 638-39.

EPA has established that these HAP invariably coexist with the surrogates and will be controlled to some extent by the same technology that controls the surrogate. See Nat'l Lime, 233 F.3d at 639. EPA need not make a numerical estimate of the correlation or discuss its variability. Id. Where alternative surrogates for or methods to control these HAP exist, EPA identified and discussed them. Sierra Club, 353 F.3d at 986. EPA has demonstrated the correlation between the HAP and the surrogates, clearly meeting the standard of reasonableness under National Lime and Sierra Club.

Response: EPA thanks the commenter for their input.

Comment Excerpt Number: 25

Comment: Organic HAP/Carbon Monoxide Emission Limits:
Ohio EPA understands that lower carbon monoxide emitted from boilers or process heaters theoretically represents more complete combustion and therefore lower organic HAP emissions. However, the proposed CO standards for both coal and gas fired emission sources may be beyond levels representing good combustion. An illustration of this point is that one expects pulverized coal fired boilers to be operating more consistently for efficient combustion while maintaining lower CO levels. Yet, a higher CO emission limit of 90 ppm is proposed for existing pulverized coal fired boilers as compared to the proposed 50 ppm for stoker boilers. Does this higher CO level for pulverized coal boilers indicate that some of the stoker boilers with low CO are merely operating under excessive combustion air levels or with substantial air infiltration? Would these stoker boilers have higher NOx emissions?

In assessing the data for boiler CO emissions, the US EPA should consider this type of balance point. Simply assessing the 12% lowest data points for CO or HAPs may include units that are running with excessive combustion air and at lower overall efficiency thereby increasing emissions of greenhouse gases also. This type of affect probably occurs most often for stoker boilers but is applicable, at a minimum, to all solid fuel fired boilers and likely to the gaseous and liquid fired source categories as well. Therefore, evaluating the emissions database for organic HAP control and the use of CO as a surrogate standard may not be a straight-forward process and may need to consider the quality of operation in defining units representing the top 12% or best operating source.

Response: See preamble for response to comments on how CO limits were modified.

Document Control Number: EPA-HQ-OAR-2002-0058-2818.1
Comment Excerpt Number: 27

Comment: In addressing whether a CO standard is representative of overall low organic HAP emissions for all sources in a source category, the US EPA may want to consider allowing compliance directly with an organic HAP standard. Performance testing could then be used in the case of any specific source to establish CO emission levels consisted with meeting the applicable organic HAP standard.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 15.

Commenter Name: Chris Korleski
Commenter Affiliation: Ohio EPA
Document Control Number: EPA-HQ-OAR-2002-0058-2818.1
Comment Excerpt Number: 31

Comment: The CO emission limit for both existing and new biomass fired boilers appears problematic. The CO emission level supposed to correspond to complete combustion of organic HAPs included dioxins and furans. However, the emission limit of dioxin and furan for fluidized bed and fuel cell boilers is a magnitude higher than for stoker boilers, while the CO limit is lower. Conversely, the CO limit is much higher for suspension burners than stokers, but still have dioxin and furan limits similar to the fluidized bed. This affect could very well be the result of variability or quality of fuels being combusted at the tested sources rather than characteristics of specific boiler types. Once again this points to US EPA better delineating biomass fuels or providing an alternative compliance format for organic HAPs other than the fixed CO emission concentration. As previously suggested, one alternative may be for direct testing of organic HAPs. Another alternative may be to consider setting standards consistent with lower moisture content allowing for better combustion.

Response: EPA revised the subcategories and CO limits for the final rule, see the preamble for discussion.

Commenter Name: Jim Griffin

Comment Excerpt Number: 52

Comment: Carbon monoxide is the most common product of incomplete combustion (PIC). Because of the associated chemical kinetics, it is one of the most difficult PICs to oxidize completely. CO emissions have historically been used as an indicator of the quality of the combustion process. The concept is that low CO emissions equate to low emissions of other organic compounds. While this is true in general, the mechanisms by which CO is formed and destroyed in the combustion process are different than for other organics. In cases where other organic compounds have been completely oxidized, CO concentrations may still be elevated. While the tendency is to think that further reductions in CO emissions will improve the quality of the combustion, and in turn minimize emissions of other organic compounds, this is not necessarily true. Instead, forcing CO emissions lower and lower ends up over-constraining the combustion process, resulting in other air quality concerns, without achieving corresponding reductions in emissions of organics.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 73.

Commenter Name: Jim Griffin

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 73

Comment: EPA has proposed CO is proposed as a surrogate for organic HAP. Demonstrating a reduction in CO emissions can demonstrate a reduction in organic HAP emissions, but only to the extent that the CO concentration level is around100 ppm. It appears that the level of organic HAP emissions becomes insensitive to CO concentration below 100 ppm.

EPA itself has already reached this conclusion in the Hazardous Waste Combustor NESHAP rulemaking:

The floor level for carbon monoxide of 100 ppmv is a currently enforceable Federal standard. Although some sources are achieving carbon monoxide levels below 100 ppmv,

it is not appropriate to establish a lower floor level because carbon monoxide is a conservative surrogate for organic HAP. Organic HAP emissions may or may not be substantial at carbon monoxide levels greater than 100 ppmv, and are extremely low when sources operate under the good combustion conditions required to achieve carbon monoxide levels in the range of zero to 100 ppmv. . . . As such, lowering the carbon monoxide floor below 100 ppmv may not provide significant reductions in organic HAP emissions. Moreover, it would be inappropriate to establish the floor blindly using a mathematical approach—the average emissions for the best performing sources—because the best performing sources may not be able to replicate their emission levels (and other sources may not be able to duplicate those emission levels) using the exact types of good combustion practices they used during the compliance test documented in our data base.

This is because there are myriad factors that affect combustion efficiency and, subsequently, carbon monoxide emissions. Extremely low carbon monoxide emissions cannot be assured by controlling only one or two operating parameters.

ACC agrees that CO is an appropriate surrogate for organic HAP, but we believe HAP emissions are minimized at levels well above the 1 or 2 ppm CO proposed for Gas 2 and liquid boilers. At CO levels below about 100 ppm, differences in organic HAP emissions are negligible. Where achievable emission limitations for organic HAP that properly reflect source category and unit variability are derived from representative data, CO should continue to be used as the compliance surrogate for organic HAP. However, the CO limits should reflect the fact that the organic HAP concentration becomes insensitive to CO level below some value (e.g., 100 ppm).

Response: Carbon monoxide is often used as an indicator of combustion conditions. Under conditions of ideal combustion, a carbon-based or hydrocarbon fuel will completely oxidize to produce only CO2 and water. Under conditions of incomplete or non-ideal combustion, a greater amount of CO will be formed. With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the production of CO would also limit the production of organics. As such, EPA is not including other options for compliance with respect to non-dioxin organic HAP; all units must meet CO limits.

Based on comments received there was insufficient data to determine if a lower threshold for CO exists. For example different thresholds were provided (100 vs 500 ppm). In the absence of specific data we computed the CO MACT floors using the data available. Also, since proposal many of the CO limits have increased, see the preamble for further discussion.

Regarding the use of oxidation catalysts to reduce organic HAP, there are permits for biomass units through the Florida Department of Environmental Protection which show organic HAP reductions via oxidation catalysts. See information for DEP File No. 0810226-001-AC.

Comment: PCAPCD objects to the proposed dioxin standards for existing and new major sources, and support setting a single standard for all biomass boiler types. For biomass boilers, the available data has not been shown to demonstrate a correlation between dioxin and CO emissions, thus sub-categorization by boiler type is not warranted. The proposed standard for stoker boilers, which is the most prevalent biomass boiler type, is not reasonably achievable by units that are well operated and maintained and does not adequately consider variability resulting from test method precision. Alternatively, PCAPCD could support a requirement for work practice standards including operation of dry PM collection devices outside of the well established dioxin formation temperature range of approximately 450 – 650 F.

Response: See preamble for final treatment of Dioxin/Furan.

Comment Excerpt Number: 10

Comment: The Agency is not compelled to issue numerical limits for a particular constituent. It can use work practices, or it can conclude that the emissions are insignificant in the context of its duty to address 90% of the designated urban air toxics. For instance, in general, the data for chlorinated dioxins for biomass boilers are non-detect. The Agency could have concluded that the data indicated that numerical limits were not necessary because of the apparently insignificant levels of emissions, however, the Agency proposed unreasonable numerical limits based on the non-detect data. The unreasonableness of the limits is demonstrated by the fact that the proposed chlorinated dioxin limits for some biomass boilers are 100 times lower than the existing limits for hazardous waste incinerators, which should be the most stringently regulated of all combustion devices.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Thomas Bakk

Document Control Number: EPA-HQ-OAR-2002-0058-2950
Comment Excerpt Number: 11

Comment: A separate specific justification is available to establish a work standard for dioxin/furans rather than MACT emission limits Under section 112(h)(2)(B), EPA may establish a work standard when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Such conditions exist regarding dioxin/furans. The proposed emission limit is so low, and the detection limits for dioxin and furan isomers is so variable that many boilers are likely to exceed the limits even though tests show the isomers are present below detection limits. Therefore, testing for compliance is not technologically practicable. Nor is it economically practicable to incur greater costs that will not resolve the inherent problem of establishing an emission limit that is below the detection limit.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Sean M. O'Keefe

Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 11

Comment: EPA has authority to prescribe a work practice standard for a HAP in lieu of a numerical emissions limit "when the application of measurement technology to a particular class of sources is not practicable due to technological and economic limitations". In the case of the proposed dioxin/furan standards, the standards are so low and the detection limits so variable that emissions testing may be incapable of distinguishing between boilers that are in or out of compliance. Since the proximity of the standard to the detection limit makes emissions testing to determine compliance technologically impracticable, a work practice standard requiring good combustion practices to minimize emissions of dioxins/furans appears well justified. A&B therefore recommends that such a standard be incorporated into the rule in lieu of the proposed numerical emission limits.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: Dioxin/Furan Emissions

EPA has proposed emission limits for dioxin/furan emissions. In many cases, emissions tests indicated emissions below detection levels, and there are very few emissions tests on which to base a standard. While D/F formation and control is fairly well known for MWC units, similar knowledge is not prevalent for conventional fuel firing, as indicated by the limited and questionable data for this rule. There is not enough valid data, and EPA has provided no documentation on the mechanisms of D/F formation in the sources affected by this rule nor of any control technologies known to control these low levels of emissions to the proposed levels. Indeed, combustion equipment and emissions control equipment suppliers in many cases cannot propose equipment and guarantee performance at these levels. Issuing a D/F standard as proposed places the regulated community at a high risk of noncompliance with no certain demonstrated options. This resultant standard is not in keeping with Congressional intent. We believe that in this case at this time, EPA needs to rethink their position and not impose D/F emission limits, but instead focus on a work practice approach based on conventional thinking relative to D/F formation. This is the recommended approach until such time as EPA can gather adequate information and valid emissions data to allow evaluation of actual formation and control methodologies so that a MACT Floor can be established if it is justified.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: The proposed dioxin/furan emission standards are very low and the detection limits of dioxin and furan isomers are so variable that many boilers are likely to exceed the proposed emission limits for dioxin/furans even though the tests show that all the isomers are present below the detection limits. As a result, EPA has a created a situation of imposing a dioxin/furan emissions limitation even though the method of demonstrating compliance may not reliably distinguish compliant boilers from noncompliant boilers.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: EPA has ample authority to prescribe a work practice standard instead of a numeric emissions limit. Section 112(h)(2)(B) authorizes EPA to establish work practice standards when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Such is the case for the proposed dioxin/furan standards. The proximity of the standard to the detection limit makes testing for compliance not technologically practicable, while the inability to accurately measure at the level of the proposed standard is economically impracticable because spending more money on the prescribed method will not resolve the inherent problem of setting the standard at the method detection limit. A work practice standard requiring good combustion practices is justified in this situation and would assure that dioxin/furan emissions are minimized.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: The 112 HAP list includes only the named compounds dibenzofuran (CAS # 132649) and 2,3,7, 8 Tetrachlorodibenzo-p-dioxin (CAS# 1746016) . Therefore, if EPA decides to adopt numeric standards, the standards must be specific to these compounds. EPA has no authority to regulate under § 112 the generic chemical categories of "dioxins" and "furans." In addition, if EPA decides to adopt numerical standards, then EPA must specify in the rule the toxic equivalency factors (TEFs) that should be used to calculate the toxic equivalents (TEQs) for dioxin/furan compounds.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: As noted earlier, the achievability of most of the proposed emissions standards is questionable due to a number of flaws in the MACT analysis, particularly the handling of non-detect values. This issue, however, is particularly significant with respect to the dioxin/furan emissions standards because virtually every proposed standard for this HAP is based, in whole or part, on non-detect values. In fact, every reported test run in all floors is less than RMB's estimated practical quantitation limit (PQL) for the test method (0.039 ng/dscfm @ 7% O2). [Footnote: RMB's estimate of PQL for D/F (TEQ PCDD/PCDF) based on as assessment of the reported in-stack detection limits for all subcategories. PQL was estimated based 3 x "MDL", where "MDL" was assumed to be the 95th percentile value of the reported detection limits.] As RMB stated earlier, in such cases where the HAP can not be accurately quantified, it is inappropriate to apply an emissions standard for that HAP. As noted in Section 112(h), the technological limitations of measuring such low pollutant levels suggest that a work practice standard would be more appropriate. Therefore, RMB recommends that EPA specify a work practice standard in place of a numerical emissions standard for D/F.

Comment: As proposed, The Boiler MACT rule requires initial and annual testing for dioxin/furan emissions. Dioxin or furan emissions are commonly expected from use of waste fuels in boilers and heaters. On June 4, 2010, on the same day this MACT rule was proposed, EPA also proposed a redefinition of Solid Waste under RCRA and very stringent rules to limit dioxin and furan emissions from boilers or heaters which utilize solid waste fuels. Those proposed rules will address the dioxin or furan emissions of concern. Significant dioxin or furan emissions are not encountered from boilers or heaters using non-solid waste fuels. There are very few EPA approved laboratories which can complete stack samples analysis for dioxin and furans. The laboratory analysis and the stack testing procedures for dioxin and furan traces are both expensive and time consuming. Again the boilers and heaters using solid waste fuels are proposed to be strictly regulated by the redefinition of solid waste and the air rules specific to those units. It would be unnecessary, inappropriate, and extremely burdensome to require the expensive testing and analysis for dioxin or furan from units using clean non solid waste fuels. The dioxin/furan emission testing requirements for this category of air emission sources should be removed from the final rule.

Comment Excerpt Number: 9

Comment: No numerical emission standard for dioxin/furans (D/Fs) should be established at this time.

EPA has established MACT floor standards for coal-fired boilers for D/Fs from an inadequate dataset and has no sound basis for supporting the assumption that a control technology is available that has been demonstrated to reduce D/Fs from coal-fired boilers exists.

One of Eastman's boilers, Boiler 30 is an excellent example of the dilemma the proposed D/F standard causes. This boiler, a pulverized coal boiler with a spray dryer absorber and ESP was tested in 2009 as part of the Phase II ICR. It is a top performer for PM and HCl and has low CO emissions. Yet, it would fail the proposed D/F standard of 0.003 ng/dscm TEQ with a stack test value of 0.006. This boiler has all the characteristics of a boiler that should have low D/F emissions. There is adequate sulfur content in the coal supply (~1 percent sulfur) to inhibit the formation of D/Fs and it had low chlorine content (~200 ppm) during the stack test. While it did have a low D/F emission rate, it still would not meet the proposed standard. While this may be an artifact of data issues related to detection limits and consistent reporting of the various boilers in EPA's limited dataset, it leaves us with the dilemma of what can possibly be done to meet the standard. Unlike hazardous waste incinerators or municipal waste incinerators, both of which can have much higher D/F emissions than coal-fired boilers, there is no known solution to reduce D/Fs. In the case of hazardous waste incinerators, many of them simply removed waste heat boilers to eliminate most of the D/F formation. In this case, it would be arbitrary and capricious for EPA to set a standard that requires sources to reduce what is already a very low emission rate with no known or demonstrated technologies available to make the reduction.

The EPA has only recently gathered any D/F emissions data from coal-fired boilers and has not yet fully developed an understanding of the variability of D/F emissions over time or an understanding of the cause of D/F emissions in coal-fired boilers. EPA has only one 3-run test from any given boiler from which to establish the MACT floor. The reported emissions of D/F are at extremely low levels very close to detection limits. EPA has not established that these levels are repeatable over time or across variations in fuel by the best-performing units. Any given unit (even the “top performers” identified in the MACT floor support memoranda) is at great peril of failing the D/F emission limit in the annual performance tests. Such a result may well be the result of normal statistical variability which has not been accounted for in EPA’s MACT floor analysis. Also, neither EPA nor the regulated sources have an adequate understanding of how to reduce or control D/F emissions from coal-fired boilers.

Comment: A work practice standard should be adopted for dioxins/furans in lieu of the infeasible emission limitations, especially those for biomass boilers. Based on available data for our fleet of major source boilers only one potentially can meet the proposed limitation for its subcategory. As detailed in technical evaluations by NCASI and in the AWC and AF&PA comments, the proposed dioxin/furan emission standards for biomass boilers are so low and the detection limits of dioxin and furan isomers are so variable that many boilers will not be able to meet the proposed emission limits, even when the tests show that all the isomers are present below the detection limits. These results indicate that imposing a dioxin/furan emissions limitation on biomass boilers would be arbitrary and capricious because the method of demonstrating compliance would not reliably distinguish compliant boilers from noncompliant boilers.

In this situation, EPA has the authority to adopt a work practice standard instead of a numeric emissions limit, per CAA 112(h)(2)(B). EPA is authorized to establish work practice standards when “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” Since this clearly is the case for biomass boilers, a work practice standard, for example, requiring good combustion practices, is justified and would assure that dioxin/furan emissions are minimized.

Comment: EPA's decision not to regulate dioxin/furan organics through the CO surrogate further belies the problems with its use of a CO surrogate for any organic HAP. Although the Agency properly (and correctly) notes that one basis for setting separate D/F standards is that these organic HAPs are formed differently than the non-D/F organic HAPs, EPA also asserts that somehow it is the "high toxicity associated with even low masses of these compounds," id., justifies setting a MACT standard for these HAPs, rather than relying on the surrogate. But the statute nowhere establishes this framework for standard setting, such that some HAPs should be regulated pollutant by pollutant because of their high toxicities, whereas others can be regulated by surrogates. On the contrary, the default under the statutory language is for the Agency to set MACT emissions standards for all listed HAP, based on the actual performance of the best performing sources, without reference to the relative toxicities of each HAP, or the costs of control or compliance with HAP-specific emissions limits. Further, as EPA is aware, other organic HAPs, including PCBs and POM are also highly toxic even at very low masses.

Comment: Dioxins/Furans (D/F)
The D/F emission limits proposed in this regulation are extremely low and the level of control provided by this regulation were identified on 75 FR 32037 of the Background Document, Section V, Item A. What are the air impacts?
"Emissions of dioxin/furans, on a total mass basis, will be reduced by 722 grams per year for existing units and 1 gram per year for new units. A discussion of the methodology used to estimate emissions and emissions reductions is presented in ``Estimation of Baseline Emissions and Emissions Reductions for Industrial, Commercial, and Institutional Boilers and Process Heaters (2010)'' in the docket.e have reviewed Table 3 – Summary of MACT Floor Results for the Organic HAP Subcategories, (existing units) on page 75 FR 32023 and Table 2 to Subpart DDDDD of Part 63 – Emission Limits for Existing Boilers and Process Heaters and found that 1,837 existing units will be affected by the D/F emission limits and testing requirements. 722 grams of D/F is equal to 1.59 lbs. On a per unit basis, this regulation will control approximately 0.39 gram/yr (0.866 x 10-3 lb/yr). The emission limits have been described as being so low that during the stack test to establish compliance with this regulation, our consultant indicated that the a facility will be attempting to detect "individual molecules" of this material.
Additional comments supplied in Section II. Background Information found on page 75 FR 32011 concerning the health effects of pollutants from ICI boilers indicate the HAP emissions associated with this rule vary from 61% of total HAP emissions are the result of HCl emissions to metals accounting for approximately 6% of total HAP emissions. The background document indicates and we agree that D/F is a probable human carcinogen. However, the EPA's Background Information does indicate:

"We do not know the extent to which the adverse health effects described above occur in the populations surrounding these facilities. However, to the extent the adverse effects do occur, this proposed rule would reduce emissions and subsequent exposures."
It appears this document has not presented EPA's understanding of the threat that D/F emissions from this source category presents to public health.
It is suggested that EPA review the following questions prior to finalizing this rule:
What portions of the annual total D/F emissions are contributed by this source category?
What are the other major sources of D/F throughout the country?
What are the current conditions for D/F exposure throughout the U.S.? Have levels been going down? Have D/F concentrations been changing? If so, by how much?
Could reductions of 722 grams/yr be achieved more effectively by examining other sources of D/F?

Comment: Pages 32017 and 32018 of the preamble state “This proposed rule includes numerical emission limits for PM, mercury, HCl, CO and D/F. The selection of numerical emission limits as the format for this proposed rule provides flexibility for the regulated community by allowing a regulated source to choose any control technology or technique to meet the emission limits, rather than requiring each unit to use a prescribed control method that may not be appropriate in each case.” Consistent with that statement, the proposed Major Source Boiler MACT does not specify required technologies for D/F control, rather it specifies an emission limit.

The preamble acknowledges that D/F can be formed outside the combustion unit. Therefore, while metal, PM, and HCl HAPs may be directly linked to feed rate controls, and organic HAPs may be linked to combustion controls and/or proper operation of the air pollution control system, there are no direct links (no specific operating or feed rate parameters) that can be limited to ensure D/F emissions will remain below the regulatory limit.

The following tables summarize the liquid fuel fired sources and stoker coal sources that make up the MACT floor for D/F:

[See submittal for Table of Sources Comprising the MACT Floor Pool for D/F]

Activated carbon injection (ACI) is indicated as an air pollution control technology that has been demonstrated to reduce D/F emissions. None of the sources in the MACT floor use ACI or apparently any other APCD for D/F control.

Considering the lack of a correlation between an operating or feed rate parameter to the D/F emission rate, UVA questions whether it is appropriate to develop a MACT floor emission rate for the liquid subcategory, with 826 sources, using data from only 3 sources or for the coal-stoker subcategory, with 361 sources, using data from only 2 sources. UVA questions whether these sources, which apparently have inherently low D/F emissions because they have no installed APCD to control D/F emissions, are representative of the existing liquid fuel fired and stoker coal boilers and should be used to determine the floor.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Robert D. Morrison
Commenter Affiliation: Abbott Laboratories
Document Control Number: EPA-HQ-OAR-2002-0058-2764.1
Comment Excerpt Number: 8

Comment: D/F emissions from stoker boilers (and other combustion units) are similarly influenced by a complex and poorly understood interaction of boiler and fuel parameters.

Because of the lack of understanding of the mechanisms for formation and reduction of D/F, it is not possible to design a control system that can be warranted by its designer to meet a specific emission limit. The emissions from the lowest-emitting units identified by the emission testing required by USEPA in 2009 result from a coincidence that cannot be predictably duplicated in other units, either with or without active control. Thus, EPA cannot rely on those units as the basis for emission limits on other units.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Robert D. Morrison
Commenter Affiliation: Abbott Laboratories
Document Control Number: EPA-HQ-OAR-2002-0058-2764.1

Comment: For D/F emissions, there is very little information as to the relationship of operations and emissions. The basis for the proposed MACT floor for D/F from Gas 2, possibly but not necessarily including at least some cases where LFG is burned, is summarized in Table 3 of the preamble (75 FR 32023). The subcategory is believed by USEPA to include 199 units, but only includes D/F emission data from 5 units, and bases the MACT floor on only a single unit. This amounts to little or perhaps no knowledge about combustion of LFG and other Gas 2 gases in order to define MACT. If a unit does not meet the emission limit based on pre-control emissions, then the availability of emission control is problematic. If carbon injection were implemented, a Gas 2unit would need a fabric filter or other particulate control in addition to an injection system in order to preclude unacceptable PM emissions. However, fabric filters for PM control are essentially nonexistent in commercial gas-fired units. Therefore, to an even greater degree than with stoker coal, the mechanisms of dioxin formation and control are not well documented, and no unit could be constructed or modified to use LFG with sufficient confidence to justify the investment.

Comment: Too few tests were completed during the floor analysis to be statistically valid. For instance, for pulverized coal category, of the 186 boilers listed, there were 10 Dioxin/Furan tests and limits were based on 2 tests. Setting critical standards on such limited data is arbitrary and capricious. The floor must be re-evaluated using valid testing methods and QA/QC prior to setting any compliance limits. The dioxin/furan testing should be dropped from this proposal and the emission limits should be replaced with work place standards, at least until such time as suitable testing methods can be properly validated and the actual emissions adequately evaluated.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 16

Comment: Currently there is no D/F data available for bagasse boilers, and there is little chance to obtain adequate data prior to EPA determining emission limits for the December 2010 final rule. Only a few bagasse boilers are operating during the current off-season, which extends until October, and off-season operation is not representative of crop season operations.

D/F is more a combustion-related HAP, and not a fuel-related HAP (i.e., D/F is not contained in the fuel). Therefore, only combustion data can be used to set a MACT floor. If EPA were to set a D/F limit for bagasse boilers, it would have to rely on combustion data from other biomass-fired boilers, which would not be representative of bagasse boilers (based on the inherent differences in bagasse boilers described previously). If a D/F limit is set in the final rule that is not representative of bagasse boilers, none of the bagasse boilers may be able to meet the new limit, and there may be no recourse except to shut the boilers down.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: We request that a work practice standard be promulgated in bagasse boilers to reduce D/F information. Suggested work practice standards include:

* Maintain compliance with the CO limit

* Implementing good combustion practices (boiler-specific plan)

* Implementing an Operations and Maintenance Plan (boiler-specific plan)

* Maintaining a minimum temperature at the outlet of the PM control device.

These work practices promote good combustion and therefore minimize D/F formation.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: W. Randall Rawson
Commenter Affiliation: American Boiler Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2698.1
Comment Excerpt Number: 21

Comment: * ABMA believes that the limits set forth in the Proposed Boiler MACT for D/F are too stringent. According to five differing tests conducted by an ABMA member company while firing biomass, the D/F level being required for biomass at new stoker units - at 0.00005 ng/meter cubed at 7% O2 – is unattainable with any current technology.

* Two tests were conducted at operating wood-fired plants; three were small-scale tests on agricultural residues. In each case the fuel was tested for chlorine in advance and then samples of the flue gas were extracted during combustion per ASTM standards, transported per ASTM standards, and tested for D/F in qualified labs.

* The lowest average emission of dioxins and furans reported in the tests or for which there was data as Toxic Equivalent (TEQ) to 2.3.7.8 Tetra (para) dioxin was 0.170 ng/standard cubic meters at 7% O2. The highest was about 0.6. Even with activated carbon injection, that under ideal conditions can remove up to 99% of D/F (as well as mercury), the new proposed limit could not be reached. Further, we are not aware of any manufacturer that would guarantee meeting the proposed limit with carbon injection, and there are few in the industry who believe that removal rates at that level can be attained consistently.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: David A. Buff

Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 28

Comment: It is also proposed that CO or THC is an adequate surrogate for D/F, and a separate D/F standard is not necessary. D/F has been proven to be related to organic HAP formation. Organic HAP is a precursor to D/F formation. Therefore, limiting CO or THC emissions will also limit D/F emissions.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 142

Comment: The proposed dioxin/furan emission standards for are so low and the detection limits of dioxin and furan isomers are so variable that many units are likely to exceed the proposed emission limits for dioxin/furans even though the tests show that all the isomers are present below the detection limits. Thus, imposing dioxin/furan emissions limitations would be arbitrary and capricious because the method of demonstrating compliance would not reliably distinguish compliant units from noncompliant ones.

In this situation, EPA has ample authority to prescribe a work practice standard instead of a numeric emissions limit under section 112(h)(2)(B) of the ACT. A work practice standard requiring good combustion practices is justified in this situation and would assure that dioxin/furan emissions are minimized.

In any event, the 112 HAP list includes only the named compounds "dibenzofurans" and 2, 3, 7, 8 tetrachlorodibenzo-p-dioxin (TCDD). Therefore, if EPA decides to adopt numeric standards, the standards should be specific to these compounds.

Recommendation: A work practice requirement should be adopted for dibenzofurans and 2, 3, 7, 8 TCDD and proposed generic regulations for dioxin/furans should not be finalized.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: As stated elsewhere in these comments, we are concerned with the lack of data collected on dioxin/furan emissions, the quality of the data collected, the lack of understanding of dioxin/furan formation and control, and the establishment of dioxin/furan emission limits at levels that facilities with test results below detection limits, much less than the limit of quantitation, would potentially violate. There have been no studies on the efficacy of emission control on dioxin/furan emissions from gas- or liquid-fired industrial boilers and process heaters at the extremely low, generally undetectable uncontrolled concentrations measured for Gas 1 and Gas 2 fuels in EPA's database. EPA should not set a numerical standard for dioxin/furan because there is not enough information to determine the appropriate level for that standard and how sources outside the top performers would be able to achieve it.

Recommendation: Do not set numerical emission limits for dioxin/furans for gas- or liquid-fired boilers or process heaters since the data are inadequate and it is unclear controls are available to allow compliance.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: Numerical dioxins/furans (D/F) are Inappropriate.
The proposed dioxin/furan emission standards are so low and the detection limits of dioxin/furan isomers are so variable that many boilers are likely to exceed the proposed emission limits for dioxins/furans even though the tests show that all the isomers are present below the detection limits for the 17 isomers. Given that the detection limit is used to differentiate between a blank and presence of an analyte, the above outcome is unreasonable and borders on absurdity.

One of Eastman's boilers, Boiler 30 is an excellent example of the dilemma the proposed D/F standard causes. This boiler, a pulverized coal boiler with a spray dryer absorber and ESP was tested in 2009 as part of the Phase II ICR. It is a top performer for PM and HCl and has low CO emissions. Yet, it would fail the proposed D/F standard of 0.003 ng/dscm TEQ with a stack test value of 0.006. This boiler has all the characteristics of a boiler that should have low D/F emissions. There is adequate sulfur content in the coal supply (~1 percent sulfur) to inhibit the formation of D/Fs and it had low chlorine content (~200 ppm) during the stack test. While it did have a low D/F emission rate, it still would not meet the proposed standard. While this may be an artifact of data issues related to detection limits and consistent reporting of the various boilers in EPA's limited dataset, it leaves the company with the dilemma of what can possibly be done to meet the standard.

Unlike hazardous waste incinerators or municipal waste incinerators, both of which can have much higher D/F emissions than coal-fired boilers, there is no known solution to reduce D/Fs. In the case of hazardous waste incinerators, many of them simply removed waste heat boilers to eliminate most of the D/F formation. In this case, it would be arbitrary and capricious for EPA to set a standard that requires sources to reduce what is already a very low emission rate with no known or demonstrated technologies available to make the reduction. Consequently, we recommend that EPA defer any action on this standard until more is known. Alternatively, EPA should replace the proposed numerical standards for dioxins/furans with work practice standards.

Comment: Minimizing Dioxin and Furan Emissions to the MACT standards is “overkill”

My work on waste-to-energy facilities in Poland indicates that the EU has extensively studied the potential harmful effects of Dioxins/Furans. They have set as a standard an emission level of 0.1 ng/m3.

The proposed MACT standards will require Dioxin/Furan control below 0.02 ng/m to 0.0004 ng/m depending on the age and type of biomass source. This is 5 to 250 times lower than the standard established by the EU. Is such a stringent standard really needed?

Understand that no biomass-fired industrial boiler included in your study database was equipped with a “Dioxin/Furan control system.” These are merely the naturally occurring levels of emissions from biomass units that typically have very low levels of chlorine (need to generate Dioxins) and relatively high temperature and time characteristics (needed to burnout Furans). As mentioned above, EPA’s practice of considering low emission levels from a selected boiler population as the result of the alleged “application” of control technologies is ludicrous.

Comment: Establish Alternate Standards for Organic HAP

EPA has established CO as the sole surrogate for organic HAP. However, many of the organic HAPs are not well represented through use of CO as a surrogate. This is particularly true in this industry sector where many boilers are seeking to reduce NOx emissions and so have tuned their boilers such that CO emissions are preferred over NOx. Ironically, this approach has been driven by other EPA mandates. By requiring the use of CO as the surrogate for organic HAPs, EPA would require these sources to alter combustion practices to now increase NOx emissions. In addition, many of the organic HAPs that are derived from biomass are readily destroyed at the high combustion zone and exhaust temperatures typical of biomass boilers. Carbon monoxide, however, has a much higher auto-ignition temperature than the predominant HAPs from biomass. As a result, CO is not a good surrogate across the range of operations typical of a biomass boiler and it is not a good surrogate for the efficacy of any control methods. For all of these reasons, we request that EPA provide alternatives to CO as the basis for HAP control, much as the agency did in the PCWP MACT rulemaking.

Document Control Number: EPA-HQ-OAR-2002-0058-2908.1
Comment Excerpt Number: 9

Comment: The very stringent emission standards EPA has proposed for dioxin/furans for all of the source categories were based, in whole or part, on data below detection limits (non-detect values). In such cases where the HAP cannot be accurately quantified, EPA should not apply an emissions standard for that HAP. The technological limitations of measuring such low pollutant levels
suggest that a work practice standard would be more appropriate. Section 112(h)(2)(B) of the CAA authorizes EPA to establish work practice standards when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Therefore, EPA should specify a work practice standard in place of any proposed emissions standard for dioxin/furans. A work practice standard requiring good combustion practices is justified in this situation and would assure that dioxin/furan emissions are minimized.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Kristine M. Krause
Commenter Affiliation: Wisconsin Electric Power Company, We Energies
Document Control Number: EPA-HQ-OAR-2002-0058-2679.1
Comment Excerpt Number: 9

Comment: The achievability of most of the proposed emissions standards is questionable due to a number of flaws in the MACT analysis, particularly the handling of non-detect values. This issue, however, is particularly significant with respect to the dioxin/furan emissions standards because virtually every proposed standard for this HAP is based, in whole or part, on non-detect values. In such cases where the HAP can not be accurately quantified, it is inappropriate to apply an emissions standard for that HAP. As noted in Section 112(h), the technological limitations of measuring such low pollutant levels suggest that a work practice standard would be more appropriate. Therefore, We Energies recommends that EPA specify a work practice standard in place of a numerical emissions standard for D/F.

Document Control Number: EPA-HQ-OAR-2002-0058-2825
Comment Excerpt Number: 2

Comment: Boise Cascade currently has no data regarding our emissions of dioxin and furans. We will begin collecting that information soon at a cost of $15,000 to $20,000 per stack test. We expect to spend a minimum of $90,000 to $120,000 company-wide just for initial dioxin/furans testing. That cost could easily double or triple if we have to conduct multiple tests to develop confidence in our ability to continuously meet the limit. Because of the expense of testing, and because of the potential variability in the dioxin/furan emissions, Boise Cascade suggests that EPA provide an additional 3 years to comply with this limit. The facility would use the annual stack test data required by the rule to develop confidence in the concentration of these pollutants in the emissions.
EPA could also use this data to consider whether the emission limits for these pollutants were appropriately set.

Document Control Number: EPA-HQ-OAR-2002-0058-3122
Comment Excerpt Number: 4

Comment: Dioxin/Furan (D/F) emission limits. The D/F emission limits are of questionable value and should be eliminated for several reasons. See "EPA's Reanalysis of Key Issues Related to Dioxin Toxicity and Response to NAS Comments" (EPA/600/R10/038A), 75 FR 28610, etc. Public exposure to D/F has declined: "In fact, as a result of the efforts of EPA, state governments and industry, known and quantifiable industrial emissions of dioxin in the United States have been reduced by more than 90% from 1987 levels" (http://www.fda.gov/Food/FoodSafety/FoodContaminants Adulteration/CheinicalContaminants/DioxinsPCBstucm077524.htin). The original rule did not contain emission limits for D/F, Control of other HAPs such as mercury will provide adequate incidental control and reduction of D/F. The cost of separately monitoring D/F is not warranted taking into consideration the cost of achieving such emission reductions, energy requirements, and environmental impacts as required by Section I12(d)(2) of the CAA. The limited emission data prevents setting an emission limit based on sound science. The coal emission limits were based on only a few units. Neither the initial source category list (EPA-450/3-91-030) or the 2004 final rule identified D/F as a pollutant to be regulated.

Comment Excerpt Number: 5

Comment: The Agency is not compelled to issue numerical limits for a particular constituent. It can use work practices, or it can conclude that the emissions are insignificant in the context of its duty to address 90% of the designated urban air toxics. For instance, in general, the data for chlorinated dioxins for biomass boilers are non-detect. The Agency could have concluded that the data indicated that numerical limits were not necessary because of the apparently insignificant levels of emissions, however, the Agency proposed unreasonable numerical limits based on the non-detect data. The unreasonableness of the limits is demonstrated by the fact that the proposed chlorinated dioxin limits for some biomass boilers are 100 times lower than the existing limits for hazardous waste incinerators, which should be the most stringently regulated of all combustion devices.

Comment Excerpt Number: 7

Comment: With the EPA Method 23, Determination of Polychlorinated Dibenzo-p-dioxins and Polychlorinated Dibenzofurans from Municipal Waste Combustors, a sample is withdrawn isokinetically from the gas stream and collected in the sample probe, on a glass fiber filter, and on a packed column of adsorbent material. The sample cannot be separated into a particle and vapor fraction. The dioxins and furans are extracted from the sample, separated by high resolution gas chromatography (HRGC), and measured by high resolution mass spectrometry (HRMS).

The detection limits for Method 23 are based on the variation in the baseline and have high variability. The detection limit of a measurement is generally defined as the minimum level of an analyte which can be differentiated from an analytical blank. Analytical chemists use Practical Quantitation Limit (PQL) to define the lowest concentration of an analyte which can be quantified at a known level of confidence. A number of different approaches are used for determining the PQL of an analytical method. One approach adopted by EPA in 40 CFR 136, Appendix B is to multiply the detection limit of an analytical method by 3.14 to obtain its PQL.

Using the detection limits provided for each dioxin/furan isomer that yielded non-detects in the EPA's Boiler MACT test runs database, the dioxin/furan analysis PQL values were calculated by applying the multiplier (i.e. 3.14). The table (see submittal for data table) shows the 95th, 75th, and 50th percentile PQL of dioxin/furan measurements as Toxic Equivalency Quantity (TEQs) ng/dscm at 7% O2.

The table shows that for tests achieving the dioxin/furan PQL at the 95th, or 75th, or 50th percentile level, the proposed limit of 0.009 TEQ ng/dscm @7% O2 (for other gas fired boilers and process heaters) is below the PQL. In other words, a facility at which all the dioxin/furan isomers are measured as being below the PQL could be considered to be in violation of the applicable standard. This is clearly unreasonable.

Given the high cost associated with dioxin/furan testing and the extremely low emission levels, which in most cases cannot be quantified or even measured by the currently available methods, we recommend not setting numeric standards but establishing work practice standards for gas fired boilers and process heaters based on good combustion practices.

Document Control Number: EPA-HQ-OAR-2002-0058-2750.1
Comment Excerpt Number: 8

Comment: The limitations for dioxin/furan are also arbitrary and capricious because these pollutants are not reliably detectable at the proposed regulatory level. As a result, the available methods of demonstrating compliance can not readily distinguish compliant boilers from noncompliant boilers. For example, the ability of tests to detect dioxin/furan at such low levels are so variable, that even boilers that are below the detection levels may still exceed the proposed emissions limitations. In addition, with levels set so low, the risk of sample contamination is extremely high; for example, "one person smoking a cigarette in the vicinity of a test program could contaminate the sample with enough dioxin to put the facility out of compliance." [see submittal for Attachment 1 at 5]. Imposing emissions limitations in this situation would be unreasonable.

Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 12

Comment: Proposed dioxin limits appear unachievable or indeterminate at best in whether and how they could be achieved. .

The proposed dioxin/furan emission standards for biomass boilers are so low and the detection limits of dioxin/furan isomers are so variable that many boilers are likely to exceed the proposed emission limits even though the tests show that most isomers are present below the detection limits. The method of demonstrating compliance would not reliably distinguish compliant boilers from noncompliant boilers. International Paper does not know whether we can achieve the proposed dioxin/furan limits or not. Dioxin formation mechanisms, conditions, and locations of formation of these substances are not well understood within boiler designs typical of our industry and very little is known about how we could come into compliance with existing or new control devices. This information is important to characterizing emissions and in designing control systems and/or work practices to control them. There is no technical certainty that the carbon injection systems asserted by EPA as a means of achieving compliance would actually work or if they will work, whether they will meet the proposed limits. The achievability of proposed dioxin limits is indeterminate at best and the ability to be achievable is severely in question thus rendering them unachievable or at least arbitrary and capricious. Therefore, we recommend that the dioxin regulations be eliminated from the rule. If EPA believes dioxin limits would be advisable, then they should undertake the massive research needed to determine mechanisms of formation (within the wide range of existing equipment types) and cost effective means of control.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: Survey of control equipment vendors for design information and for construction quotes indicates that even the manufacturers and installers of control equipment need further research to bring dioxin control to the demonstrated level of controls for other HAPs. Again, this underscores the fact that the data is not there and research needs to commence to provide the support for appropriate rulemaking.

Equipment vendors will not guarantee their equipment can meet the proposed dioxin/furan standards because the research and practical experience just isn’t there yet on which to base a guarantee.

Control equipment vendor guarantees are needed as a basis for making prudent business decisions to invest capital in equipment. Decisions about financing typically depend in part on knowing the equipment will perform the required task – compliance. The achievability of dioxin/furan control in these types of industrial boilers is in the realm of research and not demonstrated science and technology. Absence of availability of guarantees demonstrates this.

Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 15

Comment: EPA’s emissions test database for dioxin/furan is inadequate to reasonably set MACT limits.

We are concerned with the lack of data collected on dioxin and furan emissions, the quality of the data collected, the lack of understanding of dioxin and furan formation and control, and the establishment of dioxin and furan emission limits at levels that facilities with test results below detection limits would potentially violate. There have been no studies on the efficacy of emissions controls on dioxin and furan emissions from industrial boilers. EPA should not set a numerical standard for dioxins and furans because there is not enough information to determine the appropriate level for that standard and how sources outside the top performers would be able to achieve it, or even if sources identified as top performers could consistently meet the standards if additional testing was conducted.

EPA’s emissions test database for dioxin/furan is inadequate to reasonably set MACT limits. This is confirmed by the lack of data in the database for dioxin/furan in the different subcategories of boilers by which to establish the floor limits. For example in the biomass stoker subcategory, there are 320 units identified as being regulated and only 16 units with dioxin/furan data, which correlates to 5% of the total units. Of available data, only 2 of the sixteen data points were used to set the floor or just 0.6% of the units. For the pulverized coal subcategory, there are 186 units identified and only 10 units with data, or 5% of the subcategory. Only 2 of the sixteen available data points were used to set the floor or 1% of the units. This is totally insufficient data with which to establish dioxin/furan floor limits and these limits should be removed from the final rule as a result. These figures also illustrate that EPA did not appropriately use even the limited emissions data they had available. In as much as all of these units were reportedly selected as "best performing units" in EPA's testing approach and they represent less than 12% of the population of affected units, all these data, not just a small fraction, should be used to set limits.

Comment Excerpt Number: 15

Comment: We request that EPA consider work practice standards in lieu of dioxin/furan limits on biomass boilers. We have data available that indicates that dioxin/furan emissions are minimal. EPA has stated that "combustion control is most effective in reducing dioxin, furan, other organic pollutants, PM, NOx and CO emissions." (Preamble to proposed CISWI rules, 75 FR at 31942.) We believe that the CO emission limitations assure good combustion practices which in turn assure minimal dioxin/furan emissions. Dioxin/furan testing is very expensive. If a dioxin/furan limit is required, then we prefer the TEQ approach, as this has been the means to establish toxicity of the emissions. We do not see added value in
having TEQ and total measures since with the TEQ approach is the most accurate in measuring health effects of the emissions.

Comment Excerpt Number: 19

Comment: A work practice standard for dioxin/furan is more appropriate than an emissions limit, but the value of such a work practice standard is also in question.

For dioxin and furans, we believe there is so much uncertainty in testing methods, in the data, and in what that data means so as to render a standard essentially meaningless, or at least arbitrary and capricious. A work practice standard alternative may hold more value, but this is still uncertain. We understand that some ESP designs can provide conditions favorable for dioxin/furan formation and perhaps a work practice can focus on minimizing these conditions. Beyond that, the details of a work practice standard would also be an appropriate topic for further research.

Response: See preamble for final treatment of Dioxin/Furan.

Comment: EPA incorrectly states that CO emissions are not a surrogate for D/F.
In the preamble to the proposed regulation, EPA acknowledges that “CO has generally been used as a surrogate for organic HAP because CO is a good indicator of incomplete combustion and organic HAP are products of incomplete combustion.” EPA goes on to state that, “unlike other organic HAP, D/F can be formed outside the combustion unit.” EPA’s assertions contradict science. D/F are formed downstream of the combustion process from organic precursors, such as chlorinated phenols. These precursors are produced by incomplete combustion. Without such precursors, D/F cannot form. Therefore, D/F compounds indirectly form as a result of incomplete combustion. Consequently, any assertion that D/F emissions are not related to incomplete combustion is inaccurate.

Comment Excerpt Number: 20

Comment: EPA provides no justification for giving separate consideration to D/F emissions from coal-fired boilers.
Industrial, commercial, and institutional boilers and process heaters are not significant sources of D/F emissions. D/F emissions are significantly higher in combustion units burning chlorinated wastes. For this reason, the Commercial and Industrial Solid Waste Incineration (CISWI) Units rule is the proper venue to address D/F emissions. D/F emission standards are not a valuable component of the proposed rule for industrial, commercial, and institutional boilers and process heaters. EPA does not provide evidence to justify that the health effects of D/F emissions from industrial, commercial, and institutional boilers and process heaters warrant separate consideration. As stated by EPA, the principle organic HAP from coal combustion is benzene. EPA does not adequately make the case that health effects from D/F emissions are significant. It merely states that "The proposed standards establish separate emission limits for D/F because of the high toxicity associated with even low masses of these compounds." Therefore, the use of a surrogate for D/F emissions is justified.

The collection of D/F emissions data is itself inadequate, and most affected sources have no indication of their status of compliance at this time.

Comment: EPA should promulgate a work practice standard for dioxin/furan emissions from biomass boilers, the same approach it found acceptable for the Gas 1 subcategory.
The proposed dioxin/furan emission standards for biomass boilers are so low and the detection limits of dioxin and furan isomers are so variable that many boilers may be unable to demonstrate compliance even though the tests show that all isomers are present below the detection limits. Imposing a dioxin/furan emissions limitation on biomass boilers would be arbitrary and capricious because the method of demonstrating compliance would not reliably distinguish compliant boilers from noncompliant boilers.

In this situation, EPA has ample authority to prescribe a work practice standard instead of a numeric emissions limit. Section 112(h)(2)(B) authorizes EPA to establish work practice standards when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Such was the case for the Gas1 subcategory where EPA found that instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels, EPA proposed to adopt work practices requiring an annual tune up of the boiler. EPA's rationale for establishing work place standards is sound as it recognized that establishing HAP emissions limitations would provide a disincentive for a facility to switch from gas (considered a "clean fuel) to a dirtier but cheaper fuel (i.e. coal). It would be inconsistent with the emissions reductions goals of the CAA, and of Section 112 in particular, to adopt requirements that would result in an overall increase in HAP emissions.

This same rational is applicable to biomass-to-energy facilities which serve a useful waste management purpose, produce renewable energy, and have demonstrated negligible health impacts. In this situation, establishing dioxin/furan standards as proposed will provide a disincentive to manage biomass by a biomass-to energy facility which would be sacrificed in favor of landfilling, a waste management method ranked lower on EPA's solid waste management hierarchy. Severe economic impacts are expected in other industry sectors where biomass boilers are widely used, such as the furniture, sugar, and agricultural products industries. Thus, there is strong economic justification for prescribing work practice standards for biomass boilers in lieu of numeric emissions limitations for dioxin/furan emissions.

Furthermore, the proximity of the dioxin /furan standard to the detection limit makes testing for compliance not technologically practicable, while the inability to accurately measure at the level of the proposed standard is economically impracticable because spending more money on the prescribed method will not resolve the inherent problem of setting the standard at the method detection limit. A work practice standard requiring good combustion practices is justified in this situation and would assure that dioxin/furan emissions will be minimized.

Response: See preamble for final treatment of Dioxin/Furan.

Comment Excerpt Number: 24

Comment: EPA's proposal contains emission standards for dioxin/furan as toxic equivalents (TEQ). TEQ emissions are determined from a test for total dioxin/furan where TEQ factors are used to mathematically convert the measured total values to TEQ values. TEQ factors have changed over the years since the original 1989 I-TEQ to the presently used 2005 World Health Organization Toxic Equivalence Factors so setting a TEQ standard represents a potentially moving target. Considering 1) the MACT standards are based on emissions reductions at best performing units and not health effects, 2) TEQ factors are subject to change, EPA should promulgate a single dioxin/furan standard, as total mass.

Response: See preamble for final treatment of Dioxin/Furan.

Comment Excerpt Number: 34

Comment: ACC's view is that the lack of information on dioxin/furan emissions from industrial boilers and information on how to control those emissions requires that EPA set no numerical emission limit for dioxin/furan at this time. However, if EPA proceeds with development of a numerical standard, EPA should (a) establish the 95th percentile detection limit values for the 17 PCDD/F congeners as detection limit values, (b) multiply the detection limit values by 3 or a similar factor to establish the quantitation limit for each of the 17 congeners, (c) reanalyze all of the data by substituting the quantitation limit values for all measurements below the quantitation limit, and (d) set dioxin/furan standards based on these new values and the applicable toxicity equivalents. [see submittal for Table 4 Summary of Detection Limit Statistics for All Non-Detects in the Boiler MACT PCDD/F Data, ng/dscm at 7% O2]

Document Control Number: EPA-HQ-OAR-2002-0058-2998.1
Comment Excerpt Number: 34

Comment: In Any Event, a Work Practice Standard Should be Adopted for Dioxins/Furans in Lieu of Emission Standards

The proposed dioxin/furan emission standards are so low and the detection limits of dioxin and furan isomers are so variable that many boilers are likely to exceed the proposed emission limits for dioxin/furans even though the tests show that all the isomers are present below the detection limits. Thus, imposing a dioxin/furan emissions limitation would be arbitrary and capricious because the method of demonstrating compliance would not reliably distinguish compliant boilers from noncompliant boilers.

In this situation, EPA has ample authority to prescribe a work practice standard instead of a numeric emissions limit. Section 112(h) (2) (B) authorizes EPA to establish work practice standards when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Such is the case for the proposed dioxin/furan standards – the proximity of the standard to the detection limit makes testing for compliance not technologically practicable, while the inability to accurately measure at the level of the proposed standard is economically impracticable because spending more money on the prescribed method will not resolve the inherent problem of setting the standard at the method detection limit. A work practice standard requiring good combustion practices is justified in this situation and would assure that dioxin/furan emissions are minimized. In any event, the section 112 HAP list includes only the named compounds dibenzofuran and 1,3,7, 8 TCDD. Therefore, if EPA decides to adopt numeric standards, the standards must be specific to these compounds.

EPA has no authority to regulate under section 112 the generic chemical categories of “dioxins” and “furans.”

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 60

Comment: We are concerned with the lack of data collected on dioxin/furan emissions, the quality of the data collected, the lack of understanding of dioxin/furan formation and control, and the establishment of dioxin/furan emission limits at levels that facilities with test results below detection limits violate EPA’s responsibilities under the Clean Air Act. There have been no studies on the efficacy of emissions controls on dioxin/furan emissions from HCI boilers and process heaters. EPA should not set a numerical standard for dioxin/furan because there is not enough information to determine the appropriate level for that standard and how sources outside the top performers would be able to achieve it.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 122

Comment: A WORK PRACTICE STANDARD, RATHER THAN AN EMISSION LIMIT, IS APPROPRIATE FOR DIOXIN/FURAN. The proposed dioxin/furan emission standards are so low and the detection limits of dioxin/furan isomers are so variable that many boilers are likely to exceed the proposed emission limits for dioxins/furans even though the tests show that all the isomers are present below the detection limits for the 17 isomers. Given that the detection limit is used to differentiate between a blank and presence of an analyte, the above outcome is unreasonable. We strongly recommend that EPA replace the proposed numerical standards for dioxins/furans with work practice standards.

Response: See preamble for final treatment of Dioxin/Furan.

Commenter Name: Wayne Brandt
Commenter Affiliation: Minnesota Forest Industries
Document Control Number: EPA-HQ-OAR-2002-0058-3220

Comment Excerpt Number: 11

Comment: A separate specific justification is available to establish a work standard for dioxin/furans rather than MACT emission limits. Under section 112(h)(2)(B), EPA may establish a work standard when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Such conditions exist regarding dioxin/furans. The proposed emission limit is so low, and the detection limits for dioxin and furan isomers is so variable that many boilers are likely to exceed the limits even though tests show the isomers are present below detection limits. Therefore, testing for compliance is not technologically practicable. Nor is it economically practicable to incur greater costs that will not resolve the inherent problem of establishing an emission limit that is below the detection limit.

Response: See preamble for final treatment of Dioxin/Furan.

Choice of Regulated Pollutants: Hg

Comment: A study published in Science [Friedli, Hans & Radke, Lawrence. Mercury in Smoke from Biomass Fires. (Sep. 2001). Science. Retrieved from http://www.mindfully.org/Air/Mercury-Smoke-Biomass.htm] casts doubt on the reliability of emissions estimates from biomass incineration and suggests that biomass emissions of mercury can be higher than emissions from coal. The study shows a complete release of mercury contained in litter and green vegetation fuel that is different and higher than releases reported for some coal and biomass burning. The study suggests the higher releases of mercury are connected to regional differences in mercury concentrations in vegetation that coincide with the known highest dry/wet deposition rates in the northeastern and northwestern United States.

Response: In the final rule a single floor is established for mercury from all solid fuel units, including both coal/fossil solid and biobased solids. See the preamble for further discussion.

Comment: EPA's Choice of Filterable PM as a Surrogate For Non-mercury Metallic HAPs is Unlawful, Arbitrary, and Capricious.

EPA, in describing the expected reductions in HAP emissions from the its proposed standards, identifies antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, phosphorus, and selenium as the non-mercury metals emitted by ICIBPH in various amounts. 75 Fed. Reg. 32,010, 32,048. But nowhere else in the preamble to the proposed rule, or in the proposed rule language itself, does the Agency identify which specific listed HAP would be controlled by the limits on PM emissions it proposes. Nor does the Agency state or demonstrate that these HAP "invariably" appear with PM -- EPA simply asserts: "Most, if not all, non-mercury metallic HAP emitted from combustion sources will appear on the flue gas fly-ash. Therefore, the same control techniques that would be used to control the fly-ash PM will control non-mercury metallic HAP." 75 Fed. Reg. at 32,018. EPA does not claim –, and provides no detailed support to show that non-mercury metallic HAPs are "invariably" present in filterable PM, and in fact, they are not.4 See, attached hereto, Exhibit III-1 at 223-224, and Exhibit III-2. Most notably, 50 to 100% of the selenium created by coal-fired boilers exists as a vapor in exhaust gases.5 Similarly, up to 52% of the arsenic also may be present as a gas. Depending upon the fuel and control train, some of the otherwise nonvolatile trace metals, including chromium and nickel, may be present in the vapor phase. Controls on particulate matter will not capture such gaseous HAP emissions.

Nor does the Agency assert, as it must to meet the third prong of the Sierra Club surrogacy test, that PM control techniques are the "only means" by which facilities achieve controls on the non-mercury metallic HAP. Indeed, "[particulate matter] control is not the only means by which facilities 'achieve' reductions in HAP metal emissions." Sierra Club, 354 F.3d at 984. By utilizing less HAP-intensive fuels (even within EPA's proposed sub-categories), plants achieve lower emissions in non-mercury metallic HAP. [Footnote: The effect of fuel-related inputs on metallic HAP emissions differs from such inputs' effect on particulate matter for three reasons. First, the ash content of the coal used as a fuel determines the particulate matter concentration in a plant's flue gases. Exh. III-3. The summary of Powder River coal quality attached as Exh. III-4 shows that the ash content remains stable across many coals, while the trace elements can vary significantly. For example, coal from the Jacobs Ranch mine contains about 5.5% ash and lower concentrations of antimony, arsenic, cadmium, chromium, lead and selenium than coal from the Cordero mine. Thus, lower stack emissions of these elements could be obtained by burning Jacobs Ranch coal instead of Cordero coal. Alternatively, a plant could switch from a coal containing low amounts of HAPs, or to a similar coal containing higher amounts of HAPs, increasing HAP emissions without affecting particulate matter emissions. Such alterations in fuel supply thus "affect HAP metal emissions" in a far different fashion than they affect particulate matter. Sierra Club, 353 F.3d at 985.]

Comment: While asserting that "non-mercury metallic HAP tend to be on small size particles" (i.e., PM 2.5), EPA instead chose as the surrogate " PM (filterable)" – a larger diameter particle – and regulates simply "PM", defined as "any finely divided solid or liquid material, other than uncombined water...." 75 Fed. Reg. 32,065 (definition in proposed 40 CFR § 63.7575). In effect, PM filterable is chosen as the surrogate for the surrogate for non-mercury metallic HAP. As such, it also should meet the tests for surrogacy, which it does not.

As EPA acknowledges, non-mercury metallic HAPs exist primarily amidst the smallest particulates emitted by boilers (fine particulates, or PM2.5). 75 Fed. Reg. 32,065, and see Exs. III-5 through III-11. Total filterable particulates do not bear the necessary fixed relationship to non-mercury metallic HAP; the amount of non-mercury metallic HAP in total PM will vary, depending upon the balance between large and fine particles amongst those total particulates. A prescribed particulate matter limit can be met by removing larger particles, without removing all of the smaller particles on which the target HAPs are found. Control devices removing filterable particulates do not, in other words, “indiscriminately capture” non-mercury metallic HAPs “along with other particulates.” Indeed, EPA itself has found that a control device may be effective in capturing large particles without having any significant effect on emissions of metallic HAPs. 75 Fed. Reg. 31,896, 31,908 (June 4, 2010)(rejecting control technology that reduces large particles as effective for metallic HAPs because “non-mercury metallic HAP tend to be on small-size particles.”). Although the Agency does note that it based this choice on actual emissions data, showing that “the majority of the filterable PM emitted from units that are well controlled for PM is fine particulate,” this does not amount to a showing that PM2.5 (and non-mercury metallic HAP) is ‘invariably present’ in PM filterable, or that methods for controlling or limiting PM filterable “indiscriminately” capture PM2.5 (and the target HAPs). It could just as easily show that the PM controls at those units capture only larger particles, while allowing the fine particles (and the target HAPs) to escape.

The two most common particulate matter control devices (fabric filter baghouses and electrostatic precipitators) do, in fact discriminate between large particles and the fine particles bearing HAPs. Both tend to have much higher control efficiencies for big particles than small particles. [Footnote: See Exhs. III-1 (Table 1.1-7), III-2 (Fig. 8), and III-12.] Such control devices can as a result, provide low filterable particulate emissions, but high metallic HAP emissions. [Footnote: AP-42, Table 1.1-5; see also Exhs. III-13 (Table 1.1-15) and III-14 (JoAnn S. Lighty, John M. Veranth, and Adel F. Sarofim, Combustion Aerosols: Factors Governing their Size and Composition and Implications to Human Health, 50 J. Air & Waste Mgt. Assoc. 1565, 1582 (2000)).] A fine-meshed baghouse designed to capture PM2.5, in contrast, may produce similar emissions of total particulates to those of an electrostatic precipitator – but the fine-meshed baghouse will produce far lower metallic HAP emissions.

Response: The non-Hg metal HAP are very likely to be present in the particulate phase and will be captured along with the filterable PM in the primary PM control device. The partitioning of the metal HAPs is very complicated and can depend upon the fuel type, the form of the metals in the fuel, other constituents in the fuel and the time-temperature profile of the post-combustion environment. EPA's Office of Research & Development has conducted studies that showed good control of the non-Hg metal HAP followed good control of bulk PM (filterable) across the primary PM control device.

Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 11

Comment: EPA’s stated reasons for nevertheless selecting filterable particulate matter as its surrogate do not suffice. First, the agency suggests that EPA’s test method for measuring PM2.5 “is not applicable for units equipped with wet scrubbers,” which “likely will be necessary to achieve the proposed HCl emission limits,” whereas filterable particulates are more easily and affordably measured. 75 Fed. Reg. at 32,018. But the agency cannot regulate a “surrogate” that diverges from the target HAPs, however, merely because the surrogate is easily measured.]See Cement Kiln Recycling Coal. v. E.P.A., 255 F.3d 855, 865 (D.C. Cir. 2001) (difficulties in quantifying variation in emissions from units does not justify departure from statutory requirements).] The Clean Air Act requires EPA to prescribe the maximum achievable reduction in hazardous air pollution, 42 U.S.C. § 7412(d)(3); the agency may substitute a surrogate limit only if that substitution results still yields those maximal reductions.

EPA's second reason for selecting filterable particulates is that "the majority of the filterable PM emitted from units that are well controlled for PM is fine-particulate (PM2.5)." 75 Fed. Reg. 32,018. That does not, however, indicate that those units are capturing a proportionate quantity of PM2.5 (or non-mercury metallic HAPs), or that those units are well-controlled for PM2.5 (or non-mercury metallic HAP). As noted above, a pollution-reduction device may achieve large reductions in total filterable particulates, without achieving similar reductions in fine particulates. See Ex. III-12.

EPA's choice of filterable PM as a surrogate for non-mercury metallic HAPs clearly fails the Sierra Club 3-part test for an effective surrogate for those HAPs.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 10.

Commenter Name: Timothy Hunt

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 93

Comment: AF&PA also supports the use of filterable PM or TSM and not PM2.5 for addressing non-mercury metal HAPs. We agree with EPA and the reasons provided in the preamble as to why the use of filterable PM is more appropriate than PM2.5 (e.g. the PM2.5 test method (OTM 27) cannot be used in stacks with entrained water droplets, etc.). As the purpose of the MACT standards is to limit emissions of HAPs, establishing a PM2.5 emission limit as a surrogate for non-mercury metal HAPs is not appropriate.

Response: EPA acknowledges the comment and agrees. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Commenter Name: Trent A. Dougherty
Commenter Affiliation: Ohio Environmental Council
Document Control Number: EPA-HQ-OAR-2002-0058-2789.1
Comment Excerpt Number: 9

Comment: For example, using PM as a surrogate for non-mercury metallic HAPs is reasonable under ideal fuel sourcing is illegitimate under the current sourcing. It is not beyond the realm of possibility that without sourcing criteria, biomass power generation may use secondary wood sources such as processed wood, and perhaps even construction and demolition debris, which will generate similar levels of particulates as raw wood, but may contain increased concentrations of metals such as arsenic, chromium, lead and additional mercury compared to raw wood fuel stocks. Coupled with an overly narrow and thus less than protective definition of "solid waste," a large portion of these non-mercury metallic HAP emissions could go unmonitored.

Response: See preamble for response on non-hazardous secondary materials. See the Identification of Non-Hazardous Materials That Are Solid Waste for further discussion on classification of secondary materials.

Commenter Name: Chris Greissing
Commenter Affiliation: Industrial Minerals Association
Document Control Number: EPA-HQ-OAR-2002-0058-2740.2
Comment Excerpt Number: 15

Comment: EPA Fails to Support Its Decision to Use PM as a Surrogate. In the Proposed Rule, EPA elected to use particulate matter ("PM") as a surrogate for the emissions of non-mercury metallic HAPs from industrial boilers and process heaters. However, as EPA acknowledges, metallic HAP emissions can vary by fuel type. 75 Fed. Reg. 32018. Given this variability, using the low, single PM limit for all coal-fired boilers of 0.02 lb/MMBTU is not justified. The fact that most fuels "generally emit PM that includes some amount and combination of metallic HAPs" (75 Fed. Reg. 32018, emphasis added), does not establish a reasonable correlation between metallic HAPs and PM emissions, and in the absence of such a correlation the use of a surrogate is not justified.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 10.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 25

Comment: Emission limits for individual metal HAPs (or total selected metals) should be provided as an option in the rule. For boilers burning fuels which are naturally low in metal HAP content, PM control may not be necessary to adequately control HAP emissions, and the requirement to limit PM emissions may unduly burden sources with costly control devices and monitoring equipment. Sources should have the option to meet either a total selected metals limit or a PM limit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2941.1, excerpt 23.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 30

Comment: FSI agrees with EPA that all fuels do not emit the same type and amount of metallic HAP. This in fact is why PM should not be used as a surrogate for metallic HAP: it would require all sources to meet the same PM limit, regardless of how much metallic HAP is in the fuel or is emitted. This "one limit fits all" approach will impose unnecessary control and compliance costs on sources that have low metallic HAP emissions.

Metallic HAP emissions are a function of the amount of metallic HAP in the fuel, and not total PM emissions. Total PM emissions are more related to unburned carbon and ash in the fuel. The amount of metallic HAP exiting the boiler, regardless of design, will mainly be a function of the metallic HAP content of the fuel since metallic HAP is not converted or transformed in the boiler, but instead exits the boiler as PM. This is illustrated from FSI bagasse boiler data. Bagasse boilers with much less efficient PM controls and much higher PM emissions (wet scrubber control) are shown to have lower metallic HAP emissions compared to better controlled, lower emitting boilers (ESP control).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3187.1, excerpt 10.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 192

Comment: A. PM as a surrogate for non-mercury metallic HAP.
EPA chose PM as a surrogate for non-mercury metallic HAP because "[m]ost, if not all, non-mercury metallic HAP emitted from combustion sources will appear on the flue gas fly-ash. Therefore, the same control techniques that would be used to control the fly-ash PM will control non-mercury metallic HAP." Id. In addition, EPA recognizes that using PM as a surrogate will eliminate costly performance testing to comply with multiple individual standards. Id. These reasons are sufficient to sustain use of PM as a surrogate for non-mercury metallic HAP.). In National Lime, the D.C. Circuit held that as long as EPA demonstrates that there is a correlation between the HAP controlled (in that case, metals) and the surrogate (in that case, PM), "it need not quantify that correlation or assess its variability because PM control technology is such that each unit of PM emissions avoided 'carries' within it some quantum of HAP metals." Nat'l Lime Ass'n, 233 F.3d at 639. Furthermore, EPA acknowledges that most sources generally emit PM that includes some amount and combination of metallic HAP. See Bluewater Network v. EPA, 370 F.3d 1, 18 (D.C. Cir. 2004) (upholding EPA's use of hydrocarbons as a surrogate for PM

because, in part, HC contributes to PM pollution). As the D.C. Circuit has recognized, "[i]f HAP metals are invariably present in [source] PM, then even if the ratio of metals to PM is small and variable, or simply unknown, PM is a reasonable surrogate for the metals," assuming that PM control technology indiscriminately captures HAP metals, which is true here, and that there is no independent method of controlling the HAP which did not control for PM as well, which is also true here. Id.; see also Sierra Club v. EPA, 353 F.3d 976, 985 (D.C. Cir. 2004) (applying Nat'l Lime's "three-part analysis" of invariable presence, indiscriminate capture and sole method of control to uphold use of PM as a surrogate for HAP).

EPA's decision to use PM (filterable) rather than PM2.5 is also reasonable because sources with wet scrubbers cannot measure PM2.5, making the surrogate more broadly applicable. In addition, the majority of the filterable PM emitted from units that are well-controlled for PM is PM2.5. See 75 FR 32018. This conclusion is supported by emission data obtained from units not equipped with wet scrubbers during EPA's information collection effort, and so EPA's use of PM (filterable) is reasonable.

Response: EPA acknowledges the comment and agrees. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Comment: The Great Plains Synfuels Plant operates boilers that have a Flue Gas Desulfurization Unit to control SO2 emissions. This control technology is considered BACT and works by using ammonia to scrub the SO2 from the flue gas forming ammonium sulfate, which is used as a fertilizer. One of the natural functions of this FGD system is the slippage of small amounts of ammonia. This ammonia can combine with remaining low level sulfur in the flue gas to form ammonium sulfate in the atmosphere even after it passes through our Wet Electrostatic Precipitator (WESP). DGC should be considered an exception to the logic described in 75 FR 32018 (June 4, 2010) that suggests using total particulate as a surrogate for total HAPs. DGC operates an FGD where a significant amount of ammonium sulfate particulate is produced and eventually emitted from the stack and is not directly related to any HAP emissions. For this reason, PM is not a representative surrogate for HAP for DGC. The WESP works well enough to control emissions so that our most recent stack test shows only 27 lbs/hr of PM10. DGC should not be penalized for having particulate emissions that are not HAPs.

This standard does not seem practical, representative, and needs to be re-evaluated. DGC endorses the comment made by the American Chemistry Council to allow for an alternative compliance method such as a Total Selected Metals (TSM) test which would allow a facility to stack test for certain selected metals in order to demonstrate compliance with appropriate limits. TSM is an option that would provide flexibility to affected sources as an alternative to installing continuous PM monitoring.

Comment: Using PM as a surrogate will result in overregulation of bagasse boilers, even though the amount of non-mercury metallic HAPs in bagasse boiler emissions varies directly with the amount of PM. This is true for two reasons. First, for the same quantity of PM, there is a lower amount of non-mercury metallic HAPs in bagasse emissions than in other biomass fuels' emissions. This difference arises from the fact that there is a lower concentration of non-mercury metals in bagasse than in other biomass fuels. Second, bagasse boilers release higher amounts of PM than other biomass boilers. This too is due to properties in bagasse itself. Bagasse's higher moisture content and lower density causes a relatively less complete burn than is achieved with drier, denser biomass fuels, which in turn increases the relative amount of PM in bagasse emissions.

Thus, there is more, but less harmful, PM in bagasse emissions than in other biomass emissions, making PM an inappropriate surrogate in the current biomass subcategories. See Sierra Club v. EPA, 353 F.3d 976, 985 (D.C. Cir. 2004) (observing that "the best achieving sources, and what they can achieve with respect to HAPs, might not be properly identified" when using an improper surrogate). The problems that arise from using PM as a surrogate for non-mercury metallic HAPs can be addressed by placing bagasse boilers in a separate subcategory of boilers.

Response: See the preamble for discussion of a subcategory related to bagasse boilers.

Comment: Given the concentrations of metals such as arsenic, chromium, lead and mercury contamination levels that can exist in waste wood fuel streams, using PM as a surrogate for metal emissions in the boiler rules is inadequate. Biomass boilers burning contaminated wood will inevitably have greater metals emissions than those burning forest biomass, even if particulate levels are similar. A permissive set of rules that permits extensive use of secondary materials as fuel will virtually guarantee an increase in heavy metals emissions from biomass power, with emissions going undetected due to the reliance on particulate matter as a proxy for these toxins.

Response: See preamble for response on non-hazardous secondary materials. See the Identification of Non-Hazardous Materials That Are Solid Waste for further discussion on classification of secondary materials.

Comment: PM does not correlate with HAP metals except to the degree that coals have uniform metals content. For sources that have very low metals in their fuel, they may have low metal HAP emissions even with moderately high PM levels. An option for complying with metal HAP emissions standards should be provided as an alternative to meeting the PM standard. This option was contained in the original boiler MACT rule and there is no reason not to include this option in the final rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2941.1, excerpt 23.

Comment Excerpt Number: 19

Comment: EPA chose PM as a surrogate for non-mercury metallic HAP because "[m]ost, if not all, non-mercury metallic HAP emitted from combustion sources will appear on the flue gas fly-ash. Therefore, the same control techniques that would be used to control the fly-ash PM will control non-mercury metallic HAP." Id. In addition, EPA recognizes that using PM as a surrogate will eliminate costly performance testing to comply with multiple individual standards. Id. These reasons are sufficient to sustain use of PM as a surrogate for non-mercury metallic HAP. In National Lime, the D.C. Circuit held that as long as EPA demonstrates that there is a correlation between the HAP controlled (in that case, metals) and the surrogate (in that case, PM), "it need not quantify that correlation or assess its variability because PM control technology is such that each unit of PM emissions avoided 'carries' within it some quantum of HAP metals." Nat'l Lime Ass'n, 233 F.3d at 639.

Furthermore, EPA acknowledges that most sources generally emit PM that includes some amount and combination of metallic HAP. See Bluewater Network v. EPA, 370 F.3d 1, 18 (D.C. Cir. 2004) (upholding EPA's use of hydrocarbons as a surrogate for PM because, in part, HC contributes to PM pollution). As the D.C. Circuit has recognized, "[i]f HAP metals are invariably present in [source] PM, then even if the ratio of metals to PM is small and variable, or simply unknown, PM is a reasonable surrogate for the metals," assuming that PM control technology indiscriminately captures HAP metals, which is true here, and that there is no independent method of controlling the HAP which did not control for PM as well, which is also true here. Id.; see also Sierra Club v. EPA, 353 F.3d 976, 985 (D.C. Cir. 2004) (applying Nat'l Lime's "three-part analysis" of invariable presence, indiscriminate capture and sole method of control to uphold use of PM as a surrogate for HAP).

Response: EPA acknowledges the comment and agrees. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Comment Excerpt Number: 20

Comment: EPA's decision to use PM (filterable) rather than PM2.5 is also reasonable because sources with wet scrubbers cannot measure PM2.5, making the surrogate more broadly applicable. In addition, the majority of the filterable PM emitted from units that are well-controlled for PM is PM2.5.[See 75 Fed.Reg. at 32,018.] This conclusion is supported by emission data obtained from units not equipped with wet scrubbers during EPA's information collection effort, and so EPA's use of PM (filterable) is reasonable.

Response: EPA acknowledges the comment and agrees. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 27

Comment: International Paper supports using PM as a surrogate for inorganic HAP as the primary form of the standard.

A total selected metals (TSM) limit is supported but only as an alternate form of the standard as it is helpful for predominately wood-firing and particularly resinated-wood firing common in wood products facilities, furniture, etc. PM is a much more workable form of the standard for pulp and paper facilities and should be retained regardless of TSM considerations.

Response: EPA acknowledges the comment. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Comment: Use of PM as a Surrogate for Non-Mercury HAP Metals.
Morton Salt supports the Agency's use of PM as a surrogate for HAP metals. If non-mercury metallic HAPs are typically present in boiler and process heater PM, then even if the ratio of metals to PM is small and variable, or simply unknown, PM is a reasonable surrogate for the metals. Also, as EPA notes in the preamble to the proposed rule [75 FR 32018] most, if not all non-metallic HAP emitted from combustion sources will appear on the flue gas fly-ash. Therefore, the control technology installed to capture PM will capture HAP metals along with other particulates.

Response: EPA acknowledges the comment and agrees. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 4

Comment: To enhance flexibility in the proposed rule, we believe that EPA should also include a total selected metals (TSM) emission limitation as an alternative to the proposed particulate matter emission limit. NewPage believes inclusion of a TSM emission limitation as an alternative to the proposed particulate matter emission limit is appropriate since the emissions of these non-mercury metals are the hazardous air pollutants the standard is intending to regulate.

The inclusion of a TSM option will provide greater flexibility for sources while still protecting the environment from the emissions of non-mercury HAP metals. This would offer the opportunity for sources to achieve low metal HAP emissions similar to those achieved with PM, but potentially at a lower cost. As the proposed Boiler MACT rule will be extremely costly for industry, the use of the TSM alternative will help to ensure some cost savings by avoiding the installation and use of PM CEMS.

For purposes of the Boiler MACT rule, TSM would be defined as the sum of the 10 non-mercury HAP metals identified in the Clean Air Act HAP list (e.g. antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel and selenium). It would not be practical or necessary for EPA to set emission limits for each of these individual metals due to the fact that so many of them are present below detectable levels. The use of a TSM alternative is therefore appropriate, and TSM emissions can be calculated using available metals emission data for each fuel type and sub-category. The use of a total makes more sense, but EPA will need to develop a scientifically defensible method for addressing the handling of non-detect test results. This guidance on how to treat non-detects will need to be include in the rule instructions since there is no guidance in Method 29. This methodology will need to provide assurance to facilities that test results which are below measurable levels (e.g. non-detects) will not put sources in a situation of being non-compliant with the standard. In the comments submitted by NCASI, there is a lengthy discussion on analytical detection limit issues.

Comment Excerpt Number: 8

Comment: As was done in the vacated Boiler MACT standard, EPA has proposed an emissions limit for particulate matter (PM) as a surrogate for the control of metal HAPs. Unlike the vacated standard, however, this proposal does not allow for the option to comply with limits on the underlying metals themselves as an alternative to the PM limit.

Under the vacated standard, many facilities (including HC&S) that were unable to comply with the PM limit with their existing air pollution controls were able to demonstrate compliance with limits on emissions of metals and thereby avoid the need to install costly new PM emissions controls. Because metals make up only a fraction of total particulate matter emissions, control of PM to the levels proposed by EPA (for HC&S, a reduction of 80 to 90 percent from current emissions) may be unnecessary in order to achieve the desired level of control of HAP metals emissions. Since a major portion of the overall cost of compliance with the proposed rule is likely to result from the need to install new PM emissions controls, inclusion of an option to instead comply with an emissions limit on metals could again significantly reduce overall compliance costs while still meeting the objective of the rule to control emissions of hazardous air pollutants. A&B strongly encourages EPA to again include this option in the final rule as a means of increasing flexibility and reducing the overall economic impact of the rule.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 88

Comment: AF&PA supports the Agency's use of PM as a surrogate for HAP metals. If non-mercury metallic HAPs are typically present in boiler and process heater PM, then even if the ratio of metals to PM is small and variable, or simply unknown, PM is a reasonable surrogate for the metals. Also, as EPA notes in the preamble to the proposed rule [75 FR 32018] "[m]ost, if not all non-mercury metallic HAP emitted from combustion sources will appear on the flue gas fly-ash". Therefore, the control technology installed to capture PM will capture HAP metals along with other particulates.

In the preamble to the proposed rule, EPA states that the "selection of numerical emission limits as the format for this proposed rule provides flexibility for the regulated community by allowing a source to choose any control technology or technique to meet the emission limits" (page 32017). We understand EPA's approach to use particulate matter as a surrogate for non-mercury metallic HAP since metals are a component of particulate matter and testing for PM is simpler than testing for total metals. However, to enhance flexibility in the proposed rule, AF&PA believes that EPA should include a total selected metals (TSM) emission limitation as an alternative to the proposed particulate matter emission limit (i.e., the sum of the 10 non-mercury HAP metals identified in the Clean Air Act HAP list: antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, and selenium). AF&PA believes inclusion of a TSM emission limitation as an alternative to the proposed particulate matter emission limit is appropriate since the emissions of these non-mercury metals are the hazardous air pollutants the standard is intending to regulate.

We believe that inclusion of such a TSM option will provide greater flexibility for sources while still protecting the environment from the emissions of non-mercury HAP metals. This would offer the opportunity for sources to achieve low metal HAP emissions similar to those achieved with PM, but potentially at a lower cost. As the proposed Boiler MACT rule will be extremely

costly for industry, the use of the TSM alternative will help to ensure some cost savings by avoiding the installation and use of PM CEMS.
For purposes of the Boiler MACT rule, TSM would be defined as the sum of the 10 non-mercury HAP metals. It would not be practical or necessary for EPA to set emission limits for each of these individual metals due to the fact that so many of them are present below detectable levels. The use of a TSM alternative is therefore appropriate, and TSM emissions can be calculated using available metals emission data for each fuel type and sub-category.

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 90

Comment: Since EPA used PM as a surrogate for non-mercury metallic HAPs in the proposed rule it also makes sense for EPA to use the PM floor units as the total selected metals (TSM) top performers. It is appropriate for EPA to consider TSM emission information only from top PM performers since the metals data are associated with particulate emissions and EPA has determined that PM is an appropriate surrogate for non-mercury metals. Using the TSM emission data from the top PM performers will also assure that the TSM limits reflect the maximum particulate removal since the floor data are limited to only those units that are the best performers for removing particulate.
Although an alternate approach to creating a TSM limit would be for EPA to use only the available TSM-10 data to create emission limits, AF&PA does not support this approach, as the amount of data to determine the TSM floors for each subcategory would be much more limited than our proposed approach. This is due to the fact that data for all 10 non-mercury HAP metals were only collected during the ICR Phase 2 testing. Then taking the top 12% of that small dataset provides very few units to determine the floor. As stated in other sections of these comments, AF&PA is already concerned about limited data sets being used to determine these floors and this approach would worsen that situation. However, since many of the top PM performers were also in the Phase 2 testing and tested for TSM-10, using data from these units provides a more robust dataset for determining a MACT floor for TSM-10.
The submitted table shows the TSM limits calculated using the PM top performers per the MACT floor memo (we note again our concerns about data quality and urge EPA to quality assure the TSM-10 data in the database prior to finalizing any analysis, but have presented the results of our analysis of the available data in an effort to provide detailed comments).

Comment: We believe that the framework already exists in the rule to ensure that sufficient monitoring is performed for a TSM alternative standard. The proposed rule [75 FR 32056, §63.7530(b)] contains procedures for determining initial compliance with mercury and hydrogen chloride through stack testing and fuel analysis. This approach could be easily adapted for a TSM standard as well. The proposed rule [75 FR 32056, §63.7540(a)(2)] also contains procedures for determining continuous compliance with mercury and hydrogen chloride and could be adapted to TSM. If a source selects the TSM alternative, there would not be the need to continuous monitor PM emissions. While the TSM alternative may entail increased costs for stack testing and fuel analysis, the costs associated with the initial installation and on-going maintenance and manpower support for a PM continuous monitor will not be incurred.

Comment Excerpt Number: 16

Comment: EPA should provide for an alternative emission limit for the non-mercury HAP metals as was done in the prior Subpart DDDDD rule, measured by Total Selected Metals, or TSM. Sources should then be allowed to demonstrate compliance via fuel analysis or by conducting stack testing using EPA Reference Method 29 (this test is already required for Hg compliance demonstration and can provide results for the remaining metals). If EPA is sincere in its sensitivity to costs, this is a very cost-effective alternative as compared to installation and operation of PM CEMS. A TSM alternate standard is a cost-effective alternative that also provides a better correlation between the surrogate TSM measure and total HAP metals.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2941.1, excerpt 23.

Comment: Total Selected Metals as an Alternative Compliance Measure.
PM is clearly an appropriate surrogate for non-mercury metallic HAP. However, EPA should provide an alternative compliance measure for non-mercury metallic HAPs where a source burns fuel containing very little metals but sufficient PM emissions to require control under the PM provisions of the Proposed Rule. Otherwise, for those sources that burn fuel containing very little metals, EPA is simply setting a PM emission limit. In the 2004 Boiler MACT, EPA recognized that in such cases PM would not be an appropriate surrogate for metallic HAPs. See EPA-HQ-OAR-2002-0058-0013, National Emission Standards for Hazardous Air Pollutants for Industrial/Commercial/Institutional Boilers and Process Heaters; Proposed Rule, 68 FR 1,660, 1,671 (Jan. 13, 2003). EPA proposed an alternative metals emission limit set for the sum of emissions of eight selected metals: arsenic, beryllium, cadmium, chromium, lead, manganese, nickel and selenium, also known as the total selected metals or "TSM," representing "the most common and largest emitted metallic HAP from boilers and process heaters." Id. EPA determined that this alternative TSM surrogate was appropriate because sufficient information was not available for each metallic HAP for every fuel type, but a total metals number could be calculated for every fuel type. See EPA-HQ-OAR-2002-0058, National Emission Standards for Hazardous Air Pollutants for Industrial/Commercial/Institutional Boilers and Process Heaters; Final Rule, 69 FR 55,218, 55,231 (Sept. 13, 2004).

Some sources burn fuels that contain very low concentrations of metals but that have sufficient PM emissions to require control under the proposed PM MACT floor. Under those circumstances, PM would not serve as an appropriate surrogate. For these sources, it is not necessary to install controls to control the metallic HAP; rather, the benefit of such controls would be to control PM, which is not a HAP regulated under section 112. MACT standards, however, may only address HAPs. See Nat'l Lime Ass'n, 233 F.3d at 638. Section 112(d)(2) provides an express list of factors that EPA may consider in setting MACT standards – including "the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements." This list does not allow consideration of non-HAP air quality benefits, such as the co-benefits of reducing sulfur dioxide and other non-HAP emissions. Moreover, the CAA provides other mechanisms for reducing such emissions.

Allowing these sources to comply with an alternative emission limit for total selected metals (TSM) would meet EPA's objective of controlling non-mercury metallic HAP emissions without triggering unnecessary control requirements that are otherwise beyond the scope of section 112.

This is consistent with DC Circuit decisions affirming the use of surrogates in other MACTs. Where a surrogate is appropriate and defensible for some but not all sources or all pollutants in a category of pollutants, EPA has not discarded the surrogate, but instead devised parameters for its reasonable application where appropriate. For example, in this proposed rulemaking, EPA has elected to use CO for organics, but carved out one subset of organics – dioxins – to be separately controlled. Inherent in the use of a surrogate is that it will have logical limits to its appropriateness.

Comment: Congress established non-mercury metals of concern
In the 1990 Clean Air Amendments, Congress listed 10 non-mercury metals as hazardous air pollutants: antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, and selenium. EPA was instructed to set MACT standards to reduce emissions of these 10 metals. In the proposed rule, EPA appropriately selected particulate matter as a surrogate for these metals since most of them are attached to particulate matter that is captured in appropriate control devices. GP supports this surrogate selection. However, EPA should consider an alternative compliance demonstration for sources that want to control the total of these 10 metals. This would directly meet the intent of Congress to control the metals of concern.

Comment: EPA collected extensive emissions data for these metals
As part of the Information Collection Request (ICR) in support of this proposed rule, EPA required extensive emission testing by a large number of facilities. One of the tests required of the selected facilities was to analyze boiler emissions for the ten total select metals. The mere fact that EPA required analysis of TSM suggests that the Agency intended to use these data in the proposed rule, and justified the significant expense required on the part of the sources to produce it. However, EPA did not propose any limits nor did it explain in the preamble to the proposed rule why a TSM alternative was not included in the proposed rule.

Comment: This will significantly reduce compliance costs.
A TSM option will provide greater flexibility for sources while still protecting the environment from the emissions of non-mercury HAP metals. This would offer the opportunity for sources, including several GP facilities, to achieve low metal HAP emissions similar to those achieved with PM, but potentially at a lower cost.
Across the forest products industry, these rules could cost $6 billion over the next four years. This would result in severe hardship and tens of thousands of job losses in the forest products sector alone. The cost of these rules translates to tens of millions in additional capital expenditures which may not be sustainable given the economic downturn and fierce international competition. As a significant player in the forest products industry, GP could have to spend hundreds of million of dollars at its 82 solid fuel and oil-fired boilers. Were EPA to adopt the additional flexibility of a total select metals compliance option, GP could save tens of millions of dollars while still protecting the environment as envisioned by the Clean Air Act

In the 2004 Boiler MACT, EPA recognized that in such cases PM would not be an appropriate surrogate for metallic HAPs. See EPA-HQOAR-2002-0058-0013, National Emission Standards for Hazardous Air Pollutants for Industrial/Commercial/Institutional Boilers and Process Heaters; Proposed Rule, 68 Fed.Reg. 1,660, 1,671 (Jan. 13, 2003). EPA proposed an alternative metals emission limit set for the sum of emissions of eight selected metals: arsenic, beryllium, cadmium, chromium, lead, manganese, nickel and selenium, also known as the total selected metals or "TSM," representing "the most common and largest emitted metallic HAP from boilers and process heaters." Id. EPA determined that this alternative TSM surrogate was appropriate because sufficient information was not available for each metallic HAP for every fuel type, but a total metals number could be calculated for every fuel type. See EPA-HQ-OAR-2002-0058, National Emission Standards for Hazardous Air Pollutants for Industrial/Commercial/Institutional Boilers and Process Heaters; Final Rule, 69 Fed.Reg. 55,218, 55,231 (Sept. 13, 2004).

Some sources burn fuels that contain very low concentrations of metals but that have sufficient PM emissions to require control under the proposed PM MACT floor. Under those circumstances, PM would not serve as an appropriate surrogate. For these sources, it is not necessary to install controls to control the metallic HAP; rather, the benefit of such controls would be to control PM, which is not a HAP regulated under section 112. MACT standards however, may only address HAPs. See Nat'l Lime Ass'n, 233 F.3d at 638. Section 112(d)(2) provides an express list of factors that EPA may consider in setting MACT standards – including "the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements." This list does not allow consideration of non-HAP air quality benefits, such as the co-benefits of reducing sulfur dioxide and other non-HAP emissions. Moreover, the CAA provides other mechanisms for reducing such emissions.

Allowing these sources to comply with an alternative emission limit for total selected metals (TSM) would meet EPA's objective of controlling non-mercury metallic HAP emissions without triggering unnecessary control requirements that are otherwise beyond the scope of section 112.

This is consistent with DC Circuit decisions affirming the use of surrogates in other MACTs. Where a surrogate is appropriate and defensible for some but not all sources or all pollutants in a category of pollutants, EPA has not discarded the surrogate, but instead devised parameters for its reasonable application where appropriate. For example, in this proposed rulemaking, EPA has elected to use CO for organics, but carved out one subset of organics – dioxins – to be separately controlled. Inherent in the use of a surrogate is that it will have logical limits to its appropriateness.

Response: Although the vacated rule contained a TSM alternative standard, the rule also included a health based alternative to exclude manganese while complying with the TSM alternative limit. Unlike the vacated rule we are not finalizing health based alternatives and EPA determined a TSM alternative would not provide much additional flexibility to regulated sources.

The non-Hg metal HAP are very likely to be present in the particulate phase and will be captured along with the filterable PM in the primary PM control device. The partitioning of the metal HAPs is very complicated and can depend upon the fuel type, the form of the metals in the fuel, other constituents in the fuel and the time-temperature profile of the post-combustion environment. EPA's Office of Research & Development has conducted studies that showed good control of the non-Hg metal HAP followed good control of bulk PM (filterable) across the primary PM control device.

Document Control Number: EPA-HQ-OAR-2002-0058-2883.1
Comment Excerpt Number: 33

Comment: In the preamble to the proposed rule, EPA states that the selection of numerical emission limits as the format for this proposed rule provides flexibility for the regulated community by allowing a source to choose any control technology or technique to meet the emission limits. We understand EPA’s approach to use particulate matter as a surrogate for non-mercury metallic HAP since metals are a component of particulate matter, and testing for PM is simpler than

testing for total metals. However, to enhance flexibility in the proposed rule, we believe that EPA should include a total selected metals (TSM) emission limitation as an alternative to the proposed particulate matter emission limit (i.e., the sum of the 10 non-mercury HAP metals identified in the Clean Air Act HAP list: antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, and selenium). We believe inclusion of a TSM emission limitation as an alternative to the proposed particulate matter emission limit is appropriate since the emissions of these non-mercury metals are the hazardous air pollutants the standard is intending to regulate.
We believe that inclusion of such a TSM option will provide greater flexibility for sources while still protecting the environment from the emissions of non-mercury HAP metals. This would offer the opportunity for sources to achieve low metal HAP emissions similar to those achieved with PM, but potentially at a lower cost. As the proposed Boiler MACT rule will be extremely costly for industry, the use of the TSM alternative will help to ensure the installation of additional PM control technology only occurs on sources with high non-mercury metallic HAP emissions.

For purposes of the Boiler MACT rule, TSM would be defined as the sum of the 10 non-mercury HAP metals. It would not be practical or necessary for EPA to set emission limits for each of these individual metals due to the fact that so many of them are present below detectable levels. The use of a TSM alternative is therefore appropriate, and TSM emissions can be calculated using available metals emission data for each fuel type and sub-category. The use of a total makes more sense, but EPA should include in the rule instructions on how to treat non-detects since there is no guidance in Method 29.

Since EPA used PM as a surrogate for non-mercury metallic HAPs in the proposed rule, it also makes sense for EPA to use the PM floor units as the TSM top performers. It is appropriate for EPA to consider TSM emission information only from top PM performers since the metals data are associated with particulate emissions, and EPA has determined that PM is an appropriate surrogate for non-mercury metals. Using the TSM emission data from the top PM performers will also assure that the TSM limits reflect the maximum particulate removal since the floor data are limited to only those units that are the best performers for removing particulate. We considered and rejected an alternative methodology for determining a TSM limit. If EPA were to use only the available TSM data to create emission limits, data would be much more limited to determine the subcategory TSM floors. This is due to the fact that data for all 10 non-mercury HAP metals were only collected during the ICR Phase 2 testing. Then taking the top 12% of that small dataset provides very few units to determine the floor. As stated in other sections of these comments, we are already concerned about limited data sets being used to determine these floors and this approach would worsen that situation. However, since many of the top PM performers were also in the Phase 2 testing and tested for TSM-10, using data from these units provides a more robust dataset for determining a MACT floor for TSM-10. See submittal for a table showing the TSM limits calculated using the PM top performers per the MACT floor memo.

We believe that the framework already exists in the rule to ensure that sufficient monitoring is performed for a TSM alternative standard. The proposed rule [75 FR 32056, §63.7530(b)] contains procedures for determining initial compliance with mercury and hydrogen chloride through stack testing and fuel analysis. This approach could be easily adapted for a TSM standard as well. The proposed rule [75 FR 32056, §63.7540(a)(2)] also contains procedures for determining continuous compliance with mercury and hydrogen chloride and could be adapted to TSM. If a source selects the TSM alternative, there would not be the need to continuous monitor PM emissions. While the TSM alternative maybe require increased costs for stack testing and fuel analysis, the costs associated with the initial installation and on-going maintenance and manpower support for a PM continuous monitor will not be incurred.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2941.1, excerpt 23.

Comment Excerpt Number: 34

Comment: We support the use of filterable PM or TSM and not PM2.5 for addressing non-mercury metal HAPs. As the purpose of the MACT standards is to limit emissions of HAP, establishing a PM2.5 emission limit is not appropriate.

Response: EPA acknowledges the comment and agrees. It has finalized PM as a surrogate for non-Hg metals in the final rule.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 70

Comment: To enhance flexibility in the proposed rule, ACC recommends that EPA include a total selected metals (TSM) [The sum of the 10 non-mercury HAP metals identified in the Clean Air Act HAP list: antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, nickel, and selenium.] emission limitation as an alternative to the proposed PM emission limit. ACC believes inclusion of a TSM emission limitation as an alternative to the proposed PM emission limit is appropriate since the emissions of these non-mercury metals are the hazardous air pollutants the standard targets for regulation and reduction.

TSM would also offer the opportunity for sources to achieve low metal HAP emissions similar to those achieved with PM, but potentially at a lower cost, particularly where it may help avoid the installation and operation of PM continuous emissions monitoring.

A TSM approach does not require EPA to set emission limits for each of the individual metals, as so many of them are present below detectable levels. TSM emissions can be calculated using available metals emission data for each fuel type and sub-category. EPA should indicate that if individual metals are non-detect for all 3 test runs or fuel samples (using Method 29 or fuel analysis), emissions of those metals should be counted as zero.

Since EPA used PM as a surrogate for non-mercury metallic HAPs in the proposed rule it also makes sense for EPA to use the PM floor units as the TSM for top performers. It is appropriate for EPA to consider TSM emission information only from top PM best performers since the metals data are clearly associated with particulate emissions, and EPA has determined that PM is an appropriate surrogate for non-mercury metals. Using the TSM emission data from the top PM best performers to establish the floor will also assure that the TSM limits reflect the maximum degree of reduction being achieved by the best performing 12% of existing sources.

The table below shows the TSM limits calculated using the PM top performers per the MACT floor memo. [ACC notes again our concerns about data quality. We urge EPA to quality assure the TSM-10 data in the database prior to finalizing any analysis, but have presented the results of our analysis of the available data in an effort to provide detailed comments.] [see submittal for Table 7, TSM limits calculated using the PM top performers per the MACT floor memo.]

ACC believes that a framework already exists in the proposed rule to ensure that sufficient monitoring is performed for a TSM alternative standard. Proposed section 63.7530(b) of the rule contains procedures for determining initial compliance with mercury and hydrogen chloride through stack testing and fuel analysis. This approach could be easily adapted for a TSM standard as well. The proposal also contains procedures for determining continuous compliance with mercury and hydrogen chloride and could be adapted to TSM.64 If a source selects the TSM alternative, there would not be the need to continuously monitor PM emissions. While the TSM alternative may entail increased costs for stack testing and fuel analysis, the significant costs associated with the initial installation and on-going maintenance and manpower support for a PM continuous monitor would not be incurred.

Response: See the response to comment EPA-HQ-OAR-2002-0058-2941.1, excerpt 23.

Choice of Regulated Pollutants: HCl

Commenter Name: Cathy S. Woollums

Comment Excerpt Number: 4

Comment: With HCl, the emissions test information available indicate that the primary inorganic HAPs emitted from boilers and process heaters are acid gases, with HCl present in the largest amounts. Further, control technologies that would reduce HCl would also control other inorganic compounds that are acid gases. Thus, the best controls for HCl would also be the best controls for other inorganic HAPs that are acid gases. Therefore, HCl is a good surrogate for acid gas inorganic HAPs because controlling HCl will result in a corresponding control of other acid gas inorganic HAP emissions.

Response: EPA acknowledges the comment and agrees. It has finalized HCl as a surrogate for non-metallic inorganic HAP in the final rule.

Comment: B. EPA's Choice of HCl as a Surrogate For non-metal inorganic HAPs (Acid Gases) is Unlawful, Arbitrary, and Capricious.

EPA's choice of HCl as the surrogate for all non-metallic inorganic HAPs emitted by ICIBPH fails all three prongs of the Sierra Club test for the choice of a reasonable surrogate. EPA offers very little support for this choice in the preamble to the proposed rule – certainly not sufficient support to satisfy the Sierra Club three part test for surrogacy. While the emissions test data show that the primary non-metallic inorganic HAP emitted from boilers and process heaters are acid gases, with HCl present in the largest amounts, the agency does not say or show that all the other acid gases are "invariably" present when HCl is present – or that their emissions concentrations fluctuate directly with HCl emissions levels. Indeed, this is not a showing EPA can make – for example, HCN peaks intermittently when coal is burned, while HCl does not. [See submittal for Reference 9.] Moreover these pollutants are "fuel dependent" – each different combination of fuels burned will produce different proportions of these pollutants, and different peaks. An examination of the emissions profiles of three units in EPA's sampling show that the relationship between HCl and other inorganic non-metal HAPs varies by fuel mix. The emissions database and survey database in the docket support only the assertion that HCl is present in much higher concentrations than the other acid gases, but not that the other acid gases are 'invariably present' with HCl. The emissions database contains approximately 44,000 data points for major and area source boilers. A quick scan of the acid gas values shows that HCl emissions were reported in pounds per Million British Thermal Units (lb/mmBtu) and ranged from roughly 0.00001 to 0.8. The database contains information on type of fuel burned, type of control technology, and type of sample collected. Table III-1 gives examples of the information for three boilers. [See submittal for Table III-1 showing sample emission rates for acid gases from boilers burning various fuel combinations.]

Although EPA asserts that control technologies that reduce HCl also control other inorganics like chlorine and other acid gases, the agency does not say that these controls "indiscriminately capture" other acid gases, or that they are the "only" controls available for the other gases, only that the "the best controls for HCl would also be the best controls for other inorganic HAP that are acid gases." While applying the best controls on HCl may be a laudable goal, this explanation is not sufficient to support the choice of HCl as a surrogate for HF, Cl2, and hydrogen cyanide. EPA must show that these other acid gases are invariably present when HCl is present in the exhaust gases from each of the subcategories it has selected, that controls on HCl indiscriminately also capture these other acid gases, and that such controls are the only way facilities now actually achieve lowered acid gas emissions levels. This EPA fails to do with this proposal; indeed by allowing sources to "elect[] to demonstrate compliance with the HCl or mercury limit by using fuel which has a statistically lower pollutant content than the emissions limit," 75 Fed. Reg. 32,033, EPA has openly acknowledged that fuel-switching is an available method of reducing both pollutants.

Response: The acid-gas HAP (HCl, HF, HCN and Cl2) are expected to be removed using technologies that take advantage of their solubility or their acidity (or both). This will likely be done using technologies that are often used for control of SO2 or SO3 (also acidic gases). Because it is highly likely that facilities will choose to control these acid gases by applying the same technology and the means of removal for each are similar, it is logical to select one (HCl) as a surrogate to represent the control of the others.

Comment: HCl as a surrogate for non-metallic inorganic HAP.
EPA chose HCl as a surrogate for non-metallic inorganic HAP because "the emissions test information available to EPA indicate that the primary non-metallic inorganic HAP emitted from boilers and process heaters are acid gases, with HCl present in the largest amounts." 75 FR 32018. EPA found that other inorganic compounds emitted are found in much smaller quantities than HCl. Id. In addition, "[c]ontrol technologies that reduce HCl also control other inorganic compounds such as chlorine and other acid gases." EPA's reasoning is thus consistent with Nat'l Lime and Sierra Club because it has demonstrated a "[s]trong direct correlation" between HCl and acid gases, in that the data demonstrates that HCl is present in acid gas emissions, usually in the largest amounts. Sierra Club, 353 F.3d at 985. In addition, EPA has shown that the best

control technologies for HCl are also the best controls for other inorganic HAP that are acid gases. 75 FR at 32,018; see Nat'l Lime, 233 F.3d at 639. This is a sufficient basis for EPA to use HCl as a surrogate for non-metallic inorganic HAP. See Bluewater Network, 370 F.2d at 18 (EPA use of surrogate was reasonable surrogate provides a "good proxy" for regulating other emissions).

Response: EPA acknowledges the comment and agrees. It has finalized HCl as a surrogate for non-metallic inorganic HAP in the final rule.

Comment: Hydrogen chloride (HCI) appears to be an appropriate surrogate for the other acid gases under consideration, hydrogen fluoride (HF), hydrogen cyanide (HCN), and chlorine (CI2). This assessment is based on the following:

All of these gases are water soluble and can be effectively controlled by the same means (i.e. wet scrubbers or spray dryer absorbers). HCI control systems commonly operate with control efficiencies of 95% or more. While the control efficiencies of HF, HCN, and CI2 may be somewhat less than for HCI, because of their much lower uncontrolled emissions rates, these gases can still be controlled to low levels.

Compared to HCI, the emissions for the other acid gases are considerably lower.
Based on AP-42 emissions factors for coal combustion, uncontrolled HF and HCN are emitted at 12% and 0.2% the rate of HCI, respectively. While AP-42 does not list Cb emission factors for coal combustion, emissions of Cf2 from typical combustion processes are expected to be extremely low given its reactivity.

The higher toxicities of HF, HCN, and CI2 relative to HCI are more than offset by the relatively lower emissions rates of these gases. If acid gas emissions are controlled to levels that effectively limit adverse health effects from Hel exposures, the health effects from the other acid gases should also be effectively limited.

Setting conventional MACT standards for HCI as well as PM, would result in significant reductions in emissions of other pollutants, most notably for sulfur dioxide, non-condensable PM, and other non·HAP acid gases. It would likely also result in additional reductions in emissions of mercury and other HAP metals.

Response: EPA acknowledges the comment and agrees. It has finalized HCl as a surrogate for non-metallic inorganic HAP in the final rule.

Comment: The proposed dioxin/furan emission standards are so low and the detection limits of dioxin/furan isomers are so variable that many boilers are likely to exceed the proposed emission limits for dioxins/furans even though the tests show that all the isomers are present below the detection limits for the 17 isomers. Given that the detection limit is used to differentiate between a blank and presence of an analyte, the above outcome is unreasonable and completely impractical. Consequently, we recommend that EPA should replace the proposed numerical standards for dioxins/furans with work practice standards.

Comment: Our oil-fired boiler is used as an auxiliary or intermittent back-up boiler. It runs on reprocessed fuel oil also known as fire coal. And this oil is processed to meet Washington State designated specifications. Natural gas is not available in our area. The cost of the additional pollution control equipment is exorbitant when compared to the amount of pollutants that would be collected from this unit. This may lead us, ironically, to shut down our most modern boiler, run our other units harder and/or curtail our production.
The trickle-down effect includes having the fuel supplier having to decide whether or not it's worth it to continue processing the RFO if, indeed, it loses its biggest customer. This product was developed in conjunction with the state's need to provide a beneficial use for the oil and to get the used oil out of the storm drains and landfills around the state. This certainly would be an unfortunate unintended consequence from these rules.

Response: See the preamble for revisions made for limited use boilers.

Comment: "Limited Use" Category for Certain Auxiliary Boilers

Electric utilities operating auxiliary boilers will be subject to the 1B MACT rule because they are not steam generating units that produce electricity. Auxiliary boilers operate infrequently; normally during plant startups and combust either natural gas or distillate fuel. As a result, the HAP emissions from the auxiliary boilers are exceedingly low and do not pose any risk to public health.

The proposed subcategories do not adequately account for the unique characteristics of these boilers. Under the proposed rule, gas-fired auxiliary boilers are subject to work practice standards requiring an annual tune up. By contrast, the IB MACT proposed rule requires auxiliary boilers combusting distillate fuel to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not provide any additional environmental benefits.

EPA should create a limited use subcategory for boilers combusting distillate fuel that would subject those units to the same work practice standards as gas-fired units. The limited use subcategory should have a 10% capacity factor threshold. Eligibility for this subcategory would be determined based on 10% of the maximum hourly heat input of the boiler multiplied by 8760 hours per year.

Consideration of at "limited use" category is not a new approach. In Fact, the definition of "limited use" was included in EPA's original boiler MACT, 69 Fed. Reg. 55,268 (Sept. 13, 2004) (defining "limited use" subcategories to include boilers or process heaters with a rated capacity of greater than 10 MMBtu/hr and "a federally enforceable annual average capacity factor of equal to or less than 10 percent."). EPA should utilize its prior determinations and create a limited use subcategory for boilers combusting distillate fuel.

Without such a subcategory, the NESHAP would require a great deal of time and expense. In some cases, testing for the emissions could add 20 to 30%
to the total emissions for that boiler in a year. That is counterproductive to achieving emissions reductions.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 2

Comment: Duke Energy urges EPA to create a "limited use" category for existing fuel oil-fired auxiliary and plant heating industrial boilers that requires a work practice standard in lieu of an emission standard for major and area sources of HAP.
Many auxiliary and heating boilers at fossil and nuclear electric generation facilities and other industrial facilities have a maximum heat input capacity greater than 10 million Btu/hour and

burn natural gas and/or fuel oil. These units operate infrequently and then for only a limited amount of time to provide steam for startup of other sources, and/or power plant comfort heating during the winter outages when an electric generation unit is not operating. These types of auxiliary and heating boilers typically operate for less than 10% of the hours in a year (less than 876 hours per year). As a result, the HAP emissions from these boilers are exceedingly low and do not pose any risk to public health. EPA has proposed in the IB MACT rule that gas-fired auxiliary boilers will be subject to work practice standards that will require an annual tune up. By contrast, the proposed IB MACT rule would require oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The significant difference in the proposed regulatory requirements for these two types of auxiliary boilers is unnecessary and will not produce environmental benefits. Requiring work practice standards for oil-fired auxiliary boilers (similar to those allowed for existing natural gas ICI boilers) would effectively reduce emissions of HAP for this category of ICI boilers. Expensive ICI boiler replacements, reconstructions, and/or modifications to meet an emission standard will not deliver significant additional HAP reductions and the added expense cannot be justified.
EPA has the authority to create a limited use subcategory of industrial boilers that are operated infrequently because of their specialized nature and use. Section 112(d)(1) of the CAA, which mirrors earlier language found in CAA Section 111(b)(2), allows the Administrator the discretion to distinguish among “classes, types, and sizes of sources” in establishing MACT standards. Indeed EPA has previously created limited use subcategories under Section 112, such as the recent reciprocating internal combustion engine “(RICE”) MACT rule. EPA should exercise its authority to establish a “limited use” category for auxiliary and heating boilers that operate infrequently and only for a specialized use.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Southern Company’s subsidiaries own and operate (or are building) 3 natural gas-fired and 6 distillate oil-fired auxiliary boilers. These auxiliary boilers are used to generate the steam necessary to bring a main electric generating unit (EGU), either a combined cycle, a coal-fired, or a nuclear unit, on line. Since the auxiliary boilers are primarily used during unit startup, operation is generally very limited (e.g., some are limited to a 10% capacity factor, and others generally operate less than 500 hours per year). Operating time is lower for plants that have multiple units due to inter-steam piping among the units that allows one unit to be brought online utilizing the steam generated from another online unit. As a result of the limited operation, the HAP emissions from the auxiliary boilers are exceedingly low.

The auxiliary boilers are an integral part of Southern Company’s black-start plan. Black-start is the term used in the utility industry to mean the procedure of starting electric generating units with a partially or completely de-energized transmission system. Unlike automobiles which have a storage battery to aid in starting, power plants cannot start up without some electricity or steam or both available. In the unlikely event of a black-start, the auxiliary boilers would be crucial in restoring power to the grid quickly and efficiently. For emergency purposes, oil-fired auxiliary boilers also have the advantage over natural gas-fired auxiliary boilers of on-site fuel storage. In other words, oil-fired auxiliary boilers are not dependent on natural gas pipeline delivery of fuel, and therefore can use oil stored on-site, which obviously adds more robustness and energy security in such an event. Also, supercritical boilers require a steam supply for startup. Outside of black-start situations, supercritical units would require the use of an auxiliary boiler only if steam is not available from any other unit onsite. In addition to operating the auxiliary boilers for such events, the boilers may be operated periodically for short periods of time to ensure readiness and perform maintenance, generally 2 to 3 hours at a time and less than 10 total hours a month.

Under the proposed rule, gas-fired auxiliary boilers are subject to work practice standards requiring an annual boiler tune up, in lieu of stringent emission and monitoring requirements. Southern Company supports the use of work practice standards for such sources and urges EPA to maintain these requirements in its final rule. By contrast, the proposed IB MACT rule requires oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers (gas-fired and oil-fired) is unnecessary and does not produce environmental benefits.

Because auxiliary boilers operate infrequently and only as needed, it will be difficult to perform emission testing. Additionally, since the demand for these boilers is almost impossible to forecast and generally lasts less than 24 hours per usage, we cannot reasonably schedule and assemble test crews and complete all of the required testing within that period. It will certainly be impossible to provide the 60 days notice required by 40 CFR 63 for testing to coincide with times the boilers would otherwise be in operation to provide backup steam for startup of the electric generating unit. Thus, it is likely that each auxiliary boiler would have to be operated each year for the sole purpose of emission testing. This would create unnecessary boiler operation, fuel usage, and emissions, with annual operating time increases of 50% to greater than 200%.

Southern Company recommends that EPA create a separate subcategory for limited use (i.e., less than or equal to10% capacity factor), oil-fired boilers and suggests that the work practice standard currently applied to gas-fired boilers (boiler tune-up) be applied in lieu of emissions standards.

Southern Company notes that the vacated IB-MACT rule contained several limited-use subcategories, including new/reconstructed limited use solid fuels, new/reconstructed limited use liquid fuels, new/reconstructed limited use gaseous fuels, and existing limited use solid fuel. [Footnote: Limited use subcategories were not necessary for existing gas and liquid fired units because EPA had determined that the MACT floor for these units was “no emissions reductions”.] The limited use subcategory in the vacated rule applied to sources with an annual capacity factor of 10% or less, such as auxiliary boilers at electric power plants. While EPA’s decision to provide emission floors of “no emissions reductions” may no longer be possible, it is possible to set work practice standards instead of emission limits for these sources.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: An additional subcategory that EPA needs to establish is one for “limited use” units. Because limited use boilers do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers can vary significantly from those of a similar boiler operating in a steady state. A capacity utilization factor of 10% was chosen for the previous boiler MACT final rule as the best means of defining a limited use unit. This definition is equally appropriate for the current rule. Also, given the limited and sporadic operation of emergency and auxiliary boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should require
work practices in lieu of emission limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: EPA Should Have Adopted Additional Subcategories

SERs recommended that EPA adopt the following subcategories for boilers:

* Fuel type (including coal rank, bagasse, biomass by type, and oil by type);
* Boiler design type (e.g. fluidized bed, stoker, fuel cell, suspension burner);
* Duty cycle;
* Geographic location;
* Boiler size;
* Burner type (with and without low-NOx burners);
* Process heaters;
* Limited use boilers.
*

Subcategorization as outlined above was a primary flexibility concern of the SERs during the SBREFA panel. The panel report states that, “SERs commented that subcategorization is a key concept that could ensure that like boilers are compared with similar boilers so that MACT floors are more reasonable and could be achieved by all units within a subcategory using appropriate emission reduction strategies." [.SBAR Panel Report at 22.] While the Panel did recognize that the entire list of potential subcategorizations asked for by SERs was not practicable because of overlap in the categories, EPA should have proposed some additional subcategories as recommended by the panel. EPA has almost complete discretion to establish any subcategories "as appropriate". [Section 112(c)(1) of the Clean Air Act. EPA may distinguish among classes, types and sizes of sources within a category. House Report No. 101-490, Part 1 at 328.] Without the additional subcategories, it increase the cost and difficulty for many small sources to meet emissions standards when they are placed in a category that is driven by the efficiency of very different boiler units running on different fuels, under different duty cycles, and most likely designed for very different purposes. In many cases, forcing boilers into categories where they do not belong will require costly investments to meet standards that are simply not achievable for certain boiler and fuel types, while yielding small or insignificant environmental benefits. In particular, it is very hard to justify why limited use boilers should be subject to the same standards as other boilers. [This contrasts strongly with the treatment of the recent MACT standards adopted for limited use reciprocating diesel and spark ignition engines, promulgated by the Agency in 2010, creating a separate category for limited use engines and emergency use engines (e.g engines that run less than 24 hours per year). EPA does not explain the disparate treatment.] EPA did include a "limited use" subcategory for boilers with average capacity factors of 10% or less in the 2004 boiler rule.

Response: The EPA sees no technical or legal justification for creating separate subcategories for cyclone, firetube, and hybrid watertube-firetube boilers. EPA reviewed the database and identified that firetube boilers exist predominantly in both the biomass and liquid subcategories, and that the size of firetube boilers ranges widely, with most being between 0 and 50 mmBtu/hr but some of the firetube units were reported as large as 250 mmBtu/hr. Firetube boilers existing in many different affected sectors and several different boiler designs including stokers and dutch ovens.Given the wide variety of firetube boilers and the data available for the rulemaking, EPA determined it is inappropriate to further partition the database to account for firetube and non-firetube units in addition to subcategorizing according to combustor design. Further subcategorization by design type has been addressed in the final rule by establishing a combined grate/suspension firing subcategory. Please refer to the preamble for discussion of this category. See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank. Please refer to the preamble for discussion of the limited use subcategory. See response to comment EPA-HQ-OAR-2002-0058-1841.1, excerpt 2 for bagasse boiler subcategory. See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type. See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 61 for additional subcategory based on regional fuel availability or geographic location. See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size. See response to comment EPA-HQ-OAR-2002-0058-2912, excerpt 2 for separate subcategories for process heaters and boilers. Comment: EPA Should Consider a Limited Use Exemption. AEP utilizes its oil-fired industrial boilers sporadically for assisting in the start-up of an EGU or for plant heating in the winter. These boilers should be treated in a similar manner to the natural gas-fired units and be subject to work practice standards. A 10% capacity factor threshold should be considered for these types of situations.

A number of costly upgrades and retrofits would be required to comply with the proposed rule. The stacks would need to be retrofitted with platforms and access in order to meet Method 1 criteria and monitoring equipment to accommodate CO CEMS monitors as well as ports for the annual testing requirements. These costly burdens are for a fleet of industrial boilers that operate, on average, less than 300 hours per year.

In addition to preventing the necessity for costly upgrades to units that are used less than 10% of the year, the limited use exemption will lessen emissions caused by complying with the proposed rule. AEP's industrial boilers do not operate in a regular manner, therefore, AEP would have to schedule the boilers to operate additional hours, and thereby actually increase HAPs emissions, in order to complete the extensive yearly testing program. Conservatively, 10% of a boilers operation time may be forced by having to complete the testing requirements.

AEP strongly encourages the EPA to allow for a limited use exemption in the final rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 3

Comment: EPA Should Include a Limited Use Subcategory for Gaseous Fuels, Liquid Fuels, and Solid Fuels similar to the 2004 Version of the MACT rule. EPA should recognize and establish separate work practice requirements for boilers and heaters that are operated on a limited use basis. For example, Dow operates some process heaters to support certain processes only during periods of start-up by warming up heat transfer fluids to a desired temperature. In some cases, these heaters operate for a short period of time and in other cases these sources cycle on and off for a few hours in order to maintain the temperature of a process fluid above a certain point. These types of process heaters have an annual capacity factor of less than 10 percent and in some cases they operate for < 5% of the time and typically between 12 to 438 hours per year.

EPA's proposed rule for Gas 2 fuels creates significant challenges for these sources that only operate for a small number of hours per year. First, it will be impossible to conduct an annual performance test in many cases since the length of the performance test itself requires that the heater operate for ~ 24 hours in order to collect the 3, 4-hour test runs with time required before and between test runs. Second, it will be very difficult to conduct an annual tune-up of these sources that operate for only a limited period of time.

Comment: EPA should create a limited use subcategory for auxiliary boilers, similar to the previous Industrial Boiler NESHAP.

EUSGU auxiliary boilers operate during startup on an infrequent basis (10% or less a year), utilizing natural gas or distillate fuel. Recognizing that auxiliary boilers function differently than typical industrial, commercial, and institutional boilers, the EPA created a limited use subcategory in 2004 for boilers combusting distillate fuel. [Footnote: 69 Fed.Reg. 55,268 and 55,232 (Sept. 13, 2004). "Limited use units are those large units with capacity utilizations less than or equal to 10 percent…"]

Here the EPA is proposing strict emission standards and monitoring requirements for these boilers, which are seldom used, and including startup and shutdown emissions. HAP emissions from these boilers are relatively low and the imposition of an emission standard results in a cost in a cost that outweighs any environmental benefit. GCLC requests that EPA adhere to prior NESHAP promulgations for Industrial Boilers and create a limited use subcategory for boilers combusting distillate fuel.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 4

Comment: Create a subcategory for limited use boilers. Some boilers are used only for back-up of primary units that are not operating due to malfunction or maintenance. EPA should consider developing a category for "limited use boilers" that have a federally enforceable annual capacity factor equal to or less than ten percent, provided that the units are indeed backup units and not process units. This may avoid substantial investments in air pollution controls for back-up boilers, and instead address air quality impacts from these units as necessary to eomply with new hourly ambient air quality standards for SO2 and NOR.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 4

Comment: Dow has sites in which gas fired back-up boilers are kept in a warm and ready condition, but not fired. Industry calls these types of boilers "warm stand-by" boilers. Should the lower cost primary steam supplier have to go down, such as a cogeneration plant, these back-up boilers will quickly come on line to maintain steam supply. This arrangement provides reliable steam to the site while avoiding emissions by low firing of the back-up boiler. Such back-up boilers are typically fired less than 10% of the year. When such boilers are firing Gas 2 fuels, it will be very difficult to keep emissions below the proposed limits. Emissions are higher during startup and shutdown intervals than normal operation. The percent of time such boilers are in a startup or shutdown mode is much higher than for continuously operated boilers. These boilers also will not experience the benefit of 30 day emissions averaging as proposed in the rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 5

Comment: Dow supports the recordkeeping requirement that is proposed in Section 63.7555(d)(3) for limited-use boilers and process heaters. Dow further comments that this recordkeeping requirement should be the only requirement for these limited use combustion sources. The term limited-use boiler/process heater is not defined in this proposed rule. EPA should include the following definitions from the 2004 version of the MACT rule (with slight adjustments to include all types of boilers and heaters) into this final rule:

Annual capacity factor means the ratio between the actual heat input to a boiler or process heater from the fuels
burned during a calendar year, and the potential heat input to the boiler or process heater had it been operated for
8,760 hours during a year at the maximum steady state design heat input capacity.

Limited use gaseous fuel subcategory includes any boiler or process heater that burns gaseous fuels not combined with any liquid or solid fuels, burns liquid fuel only during periods of gas curtailment or gas supply emergencies, , and has a federally enforceable annual average capacity factor of equal to or less than 10 percent.

Limited use liquid fuel subcategory includes any boiler or process heater that does not burn any solid fuel
and burns any liquid fuel either alone or in combination with gaseous fuels, , and has a federally enforceable annual average capacity factor of equal to or less than 10 percent. Limited use gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergencies are not included in this definition.

Limited use solid fuel subcategory includes any boiler or process heater that burns any amount of solid
fuel either alone or in combination with liquid or gaseous fuels, and has a federally enforceable annual average capacity factor of equal to or less than 10 percent.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Boilers and Process Heaters Consolidation: Boilers and Process Heaters are consolidated into single categories of affected units in the Proposed Rules. Boilers and Process Heaters are generally designed and operated for a very different purpose. Boilers are generally operated with a variable firing rate to accommodate changing steam demands. Process Heaters are generally operated with a steady state operation to maintain a steady state consistent process flow. The resultant Carbon Monoxide emissions will be significantly different between Boilers and Process Heaters. Boilers will generally have more Carbon Monoxide emissions and will be designed to handle fluctuating firing rates. Process Heaters are tuned to operate at steady state with minimal Carbon Monoxide emissions. The resultant organic HAP emissions from Boilers and Process Heaters at Major Sources will be minimal. The good combustion and residence time in the Boilers and Process Heaters will prevent the formation of organic HAP emissions, even with some Carbon Monoxide emissions.

Response: See response to comment EPA-HQ-OAR-2002-0058-2912, excerpt 2 for separate subcategories for process heaters and boilers.

Commenter Affiliation: Alexander and Baldwin, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 6

Comment: While biomass boilers as a group tend to emit higher levels of CO than coal-fired boilers for the reasons outlined above, there can also be considerable variation in emissions from boilers within the biomass subcategory, particularly from those burning fuels with relatively high moisture content (such as bagasse). In addition to fuel characteristics, however, boiler design and operational characteristics, as well as the manner in which the boiler is integrated into plant operations, can all contribute to significant variations in emissions profiles among biomass boilers.

Under the proposed rule, most bagasse-fired boilers would be categorized as "suspension burners/Dutch ovens designed to burn biomass" and would be subject to the corresponding proposed emissions limits, including a CO limit of 1,010 ppm (corrected to three percent oxygen). Importantly, this MACT floor appears to be driven largely by emissions data from units which fire dry biomass fuels and that are significantly different in design and operation from sugar mill boilers. Since the MACT emission standards applicable to any boiler are to be based upon the performance of "similar sources", A&B believes that this proposed CO limit is not appropriate for bagasse-fired boilers.

Response: See response to comment EPA-HQ-OAR-2002-0058-1841.1, excerpt 2 for bagasse boiler subcategory.

Commenter Name: Sean M. O'Keefe
Commenter Affiliation: Alexander and Baldwin, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 7

Comment: As a result of their unique design and operational characteristics, emissions from bagasse-fired boilers, and particularly emissions of CO and particulate matter (PM), can vary considerably from those of other biomass-fired boilers. It is therefore appropriate to recognize these boilers as a distinct type or class of biomass-fired boiler and to establish a separate bagasse boiler subcategory, with its own corresponding MACT floors. A&B encourages EPA to establish a separate boiler subcategory for bagasse boilers in order to ensure that the emissions standards for these boilers are based on the performance of similar sources as required by the Clean Air Act.

Response: See response to comment EPA-HQ-OAR-2002-0058-1841.1, excerpt 2 for bagasse boiler subcategory.

Commenter Name: Debra J. Jezouit

Commenter Affiliation: Class of '85 Regulatory Response Group
Document Control Number: EPA-HQ-OAR-2002-0058-2802.1
Comment Excerpt Number: 7

Comment: EPA should establish a limited use subcategory for Boilers.

The Class of ‘85 strongly supports the creation of a limited use subcategory for Boilers. The CAA allows EPA to divide source categories into subcategories based on differences in class, type, or size. In past rulemakings, EPA has considered creating limited use subcategories as part of a NESHAP where the proposed standards for "normal" (i.e., non-limited use) sources (1) are impracticable because the measurement methodologies require continuous hours of operation; (2) would result in greater emissions because the limited use source would be required to operate substantially longer to meet a numeric emission standard; or (3) have limited effectiveness due to the short periods of time the sources typically operate. [Footnote: See, e.g., 75 Fed. Reg. 9648, 9662 (March 3, 2010) (establishing separate standards for black start units); 69 Fed. Reg. 33474, 33483 (June 15, 2004) (establishing a limited use subcategory for reciprocating internal combustion engines).] Based on these criteria, the Group believes that limited use boilers, such as auxiliary boilers operated at electric generating stations, are susceptible to subcategorization.

Electric generating stations frequently have auxiliary boilers that are used for supplying startup steam to an EGU. Auxiliary boilers are used sporadically, operated for short periods of time, have a limited capacity factor, and are often classified as a "major source" based solely on their location at a generating station. The infrequent operation of auxiliary boilers and their resulting minimal emissions make the application of pollution controls more difficult and costly than at a Boiler that is operated continuously and for extended periods of time. For example, the Proposed Rule would impose the following requirements on an auxiliary Boiler that operates an average of 131 hours per year:

Install, operate and maintain CO and oxygen continuous emissions monitoring systems ("CEMS") and a data acquisition and handling system.
Comply with CO standards on a 30-day rolling average basis.
Test annually for particulate matter ("PM") and dioxinlfuran, and potentially test annually for HC1 and mercury if compliance cannot be demonstrated through fuel-based methods. If it is assumed that compliance can be demonstrated through fuel-based methods, the Proposed Rule would require at least 15 hours of performance testing per year (three 1-hour PM runs and three 4-hour dioxinlfuran runs). If all testing for all pollutants is required, the test time increases to at least 24 hours per year (not including periods of startup and stabilization).

It would be extremely difficult for an auxiliary boiler to meet an emission standard based on a 30-day rolling average, and operating merely for the purposes of testing would result in an estimated 10-20% increase in the number of hours an auxiliary boiler operates per year. The proposed requirements are clearly impractical and excessive in light of the limited number of hours these relatively small boilers operate each year.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Pamela F. Faggert
Commenter Affiliation: Dominion
Document Control Number: EPA-HQ-OAR-2002-0058-2908.1
Comment Excerpt Number: 8

Comment: The proposed rule will affect many natural gas and distillate oil-fired auxiliary boilers within the electric utility industry. These auxiliary boilers are typically used to generate the steam necessary to bring a main electric generating unit (EGU) on line (during startup). Since auxiliary boilers are primarily operated during unit startup, operation for many of these boilers is typically very limited (e.g., on the order of 500 operating hours or less in a calendar year).

For units with such limited operation, work practice standards that EPA has proposed for units that burn natural gas would be more appropriate, feasible and much less costly. The proposed emission limits and compliance provisions for large (>10 mmBtu/hr) limited use boilers that burn distillate oil are unreasonable. The cost for sources with oil-fired auxiliary boilers to install and maintain the control equipment (and potentially monitoring equipment) necessary to meet the proposed emissions standards would be excessive, particularly for a unit that operates infrequently. In addition, since the demand for an auxiliary boiler to operate is very difficult to forecast, it is almost a certainty that each auxiliary boiler would have to be operated some time during each year for the sole purpose of emission testing. Such an outcome would result in otherwise unnecessary emissions of air pollutants and use of a valuable and not unlimited resource (low sulfur diesel fuel). For these reasons, we recommend that EPA create a separate subcategory for limited use, oil-fired boilers and suggest that the work practice standard proposed for gas-fired boilers be applied in lieu of emissions standards. The limited use subcategory should have the 10% capacity factor threshold that EPA applied in the previous (now vacated) Industrial Boiler MACT rule for several limited-use subcategories, including new/reconstructed limited use solid fuels, new/reconstructed limited use liquid fuels, and new/reconstructed limited use gaseous fuels, and existing limited use solid fuel. While EPA embraced the use of limited-use subcategories in the vacated rule, it has not provided any justification for eliminating these subcategories in the proposed rule. To the extent emission limits are retained for limited-use units, annual testing requirements should be eliminated and a more flexible testing schedule should be provided that would not require the operation of these units for the sole purpose of testing.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Document Control Number: EPA-HQ-OAR-2002-0058-1975.1
Comment Excerpt Number: 1

Comment: We operate a 10 million BTU per hour biomass boiler for approximately 130 days out of the year with only 40% of those operating days at 10 million BTUs per hour yet under the current Boiler MACT regulations we would be under the same restrictions as much larger boilers operating 365 days a year at full load. In today's economy with high unemployment, house foreclosures and a shrinking manufacturing job market, mills like ours are more important than ever and Boiler MACT in its current form puts us at great risk.

Boiler MACT under its current structure accomplishes too little for the investment required. I do not disagree that we should strive for continuous improvement but it must be done within a framework of affordability with common sense attainable goals. Under the current rules a boiler which operates 130 days / year or 14 days / year is under the same emission limits as boilers operated 365 days yet the investment could very well be the same to meet the new guidelines. The economics make it nearly impossible to justify the small impact our reduction would make to the environment. There comes a point of diminishing returns that do not appear to be justifiable. I support clean air and clean water but there are limits that struggling industries can afford.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Bagasse is produced in a sugar mill as a result of sugar being extracted from sugarcane. Bagasse is the wet fibrous material remaining after the sugarcane has been cut, ground, and repeatedly washed and pressed to recover as much sucrose as possible. Since the very beginning of its operations in the United States, the sugar producing industry has used bagasse as the primary fuel for its boilers. Bagasse boilers are specifically designed to dry and burn the bagasse in the furnace, and the boilers are wholly integrated into the operations of the sugar mills. As bagasse is produced in the sugarcane milling/grinding process, it is fed directly into the boilers, where the bagasse is dried and burned. In a typical integrated sugar mill, the burning of the bagasse generates enough heat to produce the steam and electricity needed to power the operation of the sugar mills. [See submittal for the detailed flow diagram in the foldout drawing and in Figure 1.]

Bagasse boilers exhibit several distinctive design, operating, and emission characteristics when burning bagasse. These characteristics can be summarized as follows:
(a) Bagasse boilers are uniquely designed and operated to burn bagasse
(b) Bagasse boilers are fully integrated with the sugar mill and the other boilers at the mill
(c) Bagasse is fed directly and continuously from the sugar mills to the boilers
(d) Bagasse is a unique fuel generated by an industrial process, with high moisture content, low density, wide range of particle sizes, and other unique characteristics

When these characteristics are considered together, it is clear that bagasse boilers constitute a unique class of industrial boilers. Consequently, bagasse boilers should be regulated in a separate subcategory under the revised Boiler MACT rules. This subcategory should not include other types or classes of boilers (e.g., boilers that burn other types of biomass or fossil fuel).

Many times in the past, EPA has created various subcategories in rulemaking under the Clean Air Act (CAA) because EPA has recognized that a facility's emissions can be significantly affected by the facility's fuel, design, size, age, and use. When establishing the upcoming Boiler MACT rules, EPA has the statutory authority pursuant to Section 112 of the CAA to create subcategories based on "classes, types, or sizes" of industrial boilers. Indeed, EPA has created several industrial boiler subcategories in the proposed Industrial Boiler MACT rule published on June 4, 2010.

EPA should create a subcategory for bagasse boilers because they constitute a distinct class and type of boiler. Their design and operation sets them apart from other solid fuel and biomass-fueled boilers. Their unique characteristics significantly affect the boilers? emissions. Bagasse also has distinctive fuel characteristics that affect the boilers? emissions. Creating a subcategory for bagasse boilers, based on the class or type of boiler, or fuel type, will help ensure that the MACT emissions standards for bagasse boilers are based on the performance of "similar sources," as required by the CAA. Conversely, EPA would not be able to establish an appropriate MACT floor for bagasse-fired boilers if bagasse boilers were regulated in a MACT category that includes other types or classes of solid fuel-fired or biomass-fired boilers.

2.0 BACKGROUND INFORMATION ON SUGARCANE AND SUGARCANE PROCESSING

The following discussion summarizes some basic information about sugarcane, sugarcane processing, bagasse, and bagasse boilers. Sugarcane is a member of the grass family, and is grown in numerous countries around the world, including the United States, China, India, Cuba, Venezuela, Indonesia, Australia, and many more. The cane grows year round, but typically the harvesting and milling operations occur over just a few months. In the U.S., the sugar mills typically run 24 hours per day during the milling season. The milling operations usually are completed in 4 to 6 months in Florida and Texas, and 9 months in Hawaii.
The tops and most of the leaves of the sugarcane plants are removed in the field and then the cane is brought to the mills in large trailers by truck or railcar. The typical composition of the sugarcane is presented in Table 1. [See Submittal for Table 1]

In the sugar mill, the cane is first cut into smaller pieces.[In Hawaii, but not Florida, the cane is washed in a cane "cleaner" prior to cutting. The cleaner is used to remove some of the extraneous soil that adheres to the cane when it is brought in from the fields.] Next, the sugarcane is subjected to grinding and washing, which is repeated from 4 to 8 times in a sugar mill "tandem." This process extracts as much of the sugarcane juices (primarily sucrose) as possible from the cane. This process also removes some, but not all, of the soil that may be clinging to the cane (carried in from the fields). The sugarcane juices are then clarified and evaporated to produce raw sugar crystals. Refer to the flow diagram in the foldout diagram and Figure 1.

Bagasse is the traditional name given to the cellulosic fiber and pith that remain after the sucrose juice has been extracted from a sugarcane stalk during the milling process. The composition of the biomass is changed in this process of producing bagasse from sugarcane. The typical composition of bagasses is shown in Table 2. [See submittal for Table 2]

The heat needed to operate the evaporators in the sugar production process, and the power (steam and electrical) needed to operate the mill equipment, are obtained by burning the bagasse in boilers that are specifically designed for the simultaneous drying and combustion of bagasse. The design of a sugar mill always includes the complete integration of the bagasse-burning boilers with the rest of the mill. The bagasse generated in the mill is normally sent directly to the boilers as fuel. The boilers produce steam, which in turn is used in the milling tandems (high pressure) and in the raw sugar production process (low pressure). The steam also is used in steam turbine generators to produce electricity for the mill's internal consumption. In some locations, excess electricity is fed back into the local power grid.

3.0 DESIGN AND OPERATION OF BAGASSE BOILERS

The design and operation of bagasse boilers differ significantly from other solid fuel and biomass-fired boilers. First, because bagasse contains between 48 percent and 55 percent moisture, it must be dried before it can be burned. This is accomplished in boilers specifically designed for this task. Secondly, bagasse fuel is low density and encompasses a wide range of particle sizes. A typical sample of bagasse has particle dimensions ranging from less than 100 micrometers up to a few centimeters, which is much different than the wood fired in boilers. The boilers must have specially designed feeders to spread the bagasse across the boiler.

The bagasse typically is conveyed directly and continuously from the mill to the boiler and then is dropped into chutes and fed into the boilers by means of fuel distributors. Air distributors located immediately below the fuel distributors inject air at the point where the bagasse is introduced into the boiler in order to spread the bagasse over the boiler width and length. The drying (and much of the combustion) occurs while the material is suspended in air. Hence, they are often called "suspension" boilers. However, due to the wide range of particle size and the high moisture content of the bagasse fuel, some of the bagasse is not burned completely and falls to the grate or floor below, where the combustion is completed.
Accordingly, many bagasse boilers have grates of various types, which allow additional air to mix with the fuel and thus enhance the combustion. For this reason, many bagasse boilers can also be called "stoker" boilers. In reality, bagasse boilers utilize a combination of suspension firing and grate firing, and that affects the performance of the boilers. Bagasse boilers are almost universally designed to have high furnace heat release rates [all except one bagasse boiler has a furnace heat release rate greater than 22,800 British thermal units per hour per cubic foot of furnace volume (Btu/hr-ft3)]. These high heat release rates are needed to quickly dry the wet bagasse as it is blown into the boilers. Despite the high heat release rates, the combustion temperatures are considerably lower than in other classes of boilers, due mainly to the high moisture content of the fuel.

The high heat release rates means shorter residence times for flue gases. Consequently, even though bagasse is a very clean fuel with respect to metals, sulfur, and chlorine, the wet bagasse and the shorter residence times in the boiler result in an incomplete burn out of carbon monoxide (CO). As a result of these factors, the concentrations of CO in the furnace gases can be very high in comparison with the CO emissions from other classes of boilers. Conversely, the lower temperature in the furnace results in significantly lower nitrogen oxides (NO_x) emissions compared with other classes of boilers.

The variety of sugarcane entering the mill fluctuates frequently, which causes the bagasse characteristics to fluctuate in turn. Different sugarcane varieties can cause differences in bagasse particle size, moisture content, and other fuel constituents. Different varieties are grown on different types of land, such as muck or sand lands. These differing soil types affect the amount and constituents of soil that enter the sugar mill with the sugarcane. Harvesting techniques and weather conditions (i.e., rainy or wet weather) can also affect the amount of soil brought in with the sugarcane, as well as the moisture content. Although the sugarcane undergoes a washing process to become bagasse, all of these variables lead to variability in the bagasse fuel characteristics. These in turn continually affect the combustion process in the boilers.

Normally, bagasse generated in the mill is fed directly to the boilers, without any intermediate storage. No blending or further processing of the bagasse takes place prior to combustion in the boilers. This characteristic of bagasse boilers differs from other biomass-fired boilers. Because the boilers receive the bagasse as it is produced, the performance of the boilers can be adversely affected when there is variability in the moisture content, particle size distribution, or other characteristics of the bagasse being produced by the sugar mill. Since the bagasse fuel characteristics often fluctuate significantly, particularly moisture content, there often is considerable variability (minute-to-minute and hour-to-hour) in the CO concentrations and emissions from bagasse boilers. Various authors have studied the effects of these combustion characteristics on bagasse boilers, and in particular CO emissions, as presented in Section 6.0.

All of the mill's boilers are tied into a single steam header, which provides high-pressure steam to the sugar mill tandems that grind the sugarcane. The integrated operations of the boilers and the sugar mill tandems is a unique feature of sugar mills. High-pressure steam is also provided to steam turbine electrical generators, and low pressure steam is provided to the raw sugar manufacturing process.

Because all of the operations are integrated (i.e., linked together), the boilers' emission rates are affected by mill steam demand, mill upsets, startups/shutdowns, and other events occurring in the mills that affect steam consumption and affect the steam load on the boilers. Operating conditions in one boiler can also adversely affect the other boilers, again due to the effect on steam demand.

Section 6.0 contains additional technical information concerning the unique design features of bagasse boilers. Section 6.0 also contains additional technical information comparing bagasse boilers to wood- fired boilers. This information further demonstrates the significant differences between bagasse boilers and other biomass and wood-fired boilers.

4.0 EPA'S STATUTORY AUTHORITY TO CREATE SUBCATEGORIES

Section 112 of the CAA contains the statutory requirements for establishing emission standards for industrial boilers based on the use of maximum achievable control technology (MACT). Section 112(d)(1) of the CAA expressly authorizes EPA to establish subcategories:
The [EPA] Administrator shall promulgate regulations establishing emission standards for each category or subcategory of major sources…The Administrator may distinguish among classes, types, and sizes of sources within a category or subcategory in establishing such standards…

Section 129 of the CAA also authorizes EPA to distinguish between classes, types, and sizes of units when setting MACT standards for incinerators. When construing Section 129, the U.S. Court of Appeals noted that EPA has "broad discretion to differentiate among units in a category" while setting MACT standards. Northeast Maryland Waste Disposal Authority v. EPA, 358 F.3d 936, 946 (D.C. Cir. 2004). The court concluded that the term "class" is "not defined in the Clean Air Act, and the dictionary definition – „a group, set, or kind marked by common attributes' – could hardly be more flexible." Id. The court's analysis implies that EPA may reasonably establish subcategories based on a "class" whenever EPA finds that there is a "group, set, or kind" of unit (boiler, incinerator, etc.) marked by common attributes.
EPA has exercised its discretionary authority to create subcategories in many prior MACT rulemaking proceedings. For example, EPA previously created subcategories when EPA set the MACT emissions standards for industrial boilers, electric utility steam generating units, and municipal waste combustors.
EPA created these subcategories because EPA wanted to account for the differences between source types, the types of fuel used, the size of the regulated units, and other factors. In EPA's "Notice of
Regulatory Finding on the Emissions of Hazardous Air Pollutants from Electric Utility Steam Generating
Units" [Federal Register (FR), December 20, 2000], EPA stated:
In developing standards under Section 112(d) to date, the EPA has based subcategorization on considerations such as: the size of the facility, the type of fuel used at the facility, and the plant type. The EPA may also consider other relevant factors such as geographic conditions in establishing subcategories.
In EPA's 2004 MACT proposal for electric utility steam generating units (Utility MACT) (FR, January 30,
2004), EPA stated that it has broad discretion to create subcategories based on these same criteria (i.e., size of the facility, type of fuel used, and plant type) [p. 4664]. In addition, "EPA also is free to consider other relevant factors, such as geographic factors, process design or operation, variations in emission profiles, or differences in the feasibility of application of control." [p. 4664]. In the Utility MACT,
EPA exercised its discretion by proposing to create five separate subcategories for coal-fired electric utility boilers [p. 4666]. Four of the proposed subcategories were based on the type of coal burned
(i.e., bituminous/anthracite, sub-bituminous, lignite, and coal refuse). The fifth subcategory was based on the type of process used by the utility to convert coal into electricity (i.e., integrated gasification combined cycle technology).
In EPA's 2008 MACT proposal for mercury cell chlor-alkali plants (73 FR 33258; June 11, 2008), EPA noted that "EPA's broad authority to establish categories and subcategories of

industry sources is firmly established, and has been recognized as entitled to substantial deference by the U.S. Court of Appeals for the D.C. Circuit and the U.S. Supreme Court." [p. 33273]. In defense of its decision to create a subcategory for mercury cell chlor-alkali plants, EPA stated that "we have a long history of using subcategorization….

Subcategories, or subsets of similar emission sources within a source category, may be defined if technical differences in emissions characteristics, processes, control device applicability, or opportunities for pollution prevention exist within the source category. This policy is supported by Section 112(d)(1), the legislative history, our prior rulemakings, and judicial precedent." (emphasis added) [Id.]

Most recently in EPA's 2010 MACT proposal for industrial boilers (FR, June 4, 2010), EPA stated that the

CAA allows EPA to divide source categories into subcategories based on differences in class, type or size

[p. 32016]. EPA states:

For example, differences between given types of units can lead to corresponding differences in the nature of emissions and the technical feasibility of applying emission control techniques. The design, operating, and emissions information that EPA has reviewed indicates differences in unit design that distinguish different types of boilers. Data indicate that there are significantdesign and operational differences between units that burn coal, biomass, liquid, and gaseous fuels. Boiler systems are designed for specific fuel types and will encounter problems if a fuel with characteristics other than those originally specified is fired…. The design of the boiler or process heater, which is dependent in part on the type of fuel being burned, impacts the degree of combustion. Boilers and process heaters emit a number of different types of HAP emissions. Organic HAP are formed from incomplete combustion and are influenced by the design and operation of the unit. The degree of combustion may be greatly influenced by three general factors: Time, turbulence, and temperature. Within the basic unit types there are different designs and combustion systems that, while having a minor effect on fuel-related HAP emissions, have a much larger effect on organic HAP emissions. Therefore, we decided to further subcategorize based on these different unit designs but only in proposing standards for organic HAP emissions.

EPA has previously used criteria such as furnace heat release rate in developing New Source Performance Standards (NSPS) subcategories for boilers. For example, Title 40, Part 60 of the Code of Federal Regulations (40 CFR 60), Subpart Db, contains separate NO_x limits for low heat release rate boilers and high heat release rate boilers burning fuel oil. For purposes of Subpart Db, a high heat release rate is defined as greater than 70,000 Btu/hr-ft3 and a low heat release rate as less than or equal to 70,000 Btu/hr-ft3.

Another example of EPA using subcategories to set emission standards involved the NSPS for municipal waste combustors (MWCs) in 40 CFR 60, Subpart Ea. In this rulemaking, EPA set new standards for two categories of MWC unit types. In the 1995 emission guidelines, EPA identified three distinct types of MWC units that burn refuse-derived fuel (RDF), as follows: (1) RDF stoker, (2) pulverized coal/RDF mixed fuel-fired combustor, and (3) spreader stoker coal/RDF mixed fuel-fired combustor. Recently, EPA identified two additional types of RDF-fired MWC designs that do not fit within the three types of RDF combustors defined in the regulations. Since none of the three previous subcategories of RDF municipal waste combustors correctly describe the design or operation of these particular units, EPA recognized a need to add combustor types that would adequately describe and set CO emission limits for these

combustors. The EPA therefore added definitions for “spreader stoker RDF-fired combustor/100 percent coal capable” and “semi-suspension RDF-fired combustor/wet RDF process conversion.” This latter subcategory was defined as follows:
Semi-suspension refuse-derived fuel-fired combustor/wet refuse-derived fuel process conversion means a combustion unit that was converted from a wet refuse-derived fuel process to a dry refuse-derived fuel process, and because of con

Response: Please refer to the preamble for discussion of a combined grate/suspension firing subcategory. This subcategory includes bagasse units however is based on design features, and is not specific to fuel type. Bagasse boilers that have a fuel cell combustor design will be covered under the fuel cell category,

Comment: The Clean Air Act also provides EPA with broad discretion to subcategorize within the Boiler source category based on size, type, and class of source to help ensure that the emission limits are determined by the best performing similar sources and that the emission standard can be ultimately achieved in practice.

Then within the proper subcategory, EPA has the discretion to use a method for setting emission standards based on what real world best performing units actually achieve so that the units setting the bar for the rest of the subcategory will not have additional emission control obligations.

If the EPA were to use the discretion provided in the Clean Air Act, it could significantly alleviate the burden of this rule without compromising the environmental benefits that Congress intended. Flexible approaches in the Boiler MACT rule that appropriately address the diversity of units, operations, sectors, and fuels could prevent severe job losses and billions of dollars in unnecessary regulatory costs.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Comment: Back-up Boilers. The proposed rule does not include a subcategory for limited use units or a de minimis applicability threshold for small/limited use units.

A number of the Maine Mills operate liquid and/or gaseous fossil fuel-fired unit that operate at a 10% annual capacity factor or less. These units typically operate only when the primary units are down due to malfunction or maintenance (e.g., annual mill outages). Many of the events that trigger the need to operate the back-up units are unpredictable. For example, AF&PA estimates that it will cost $10 million to upgrade a relatively small package boiler used primarily during mill shutdowns and to start up the Mill's primary boilers. This is a huge capital investment for very little environmental improvement. These standby boilers should be treated differently than boilers that run all year. It is simply not cost effective to install multi-million dollar add-on pollution control (such as an Electrostatic Precipitator) for a source that operates at 10% capacity or less annually. It would also be difficult to meet the testing requirements for these units. The Mills would likely have to schedule testing and operate the boilers only for the purpose of testing, even if they are not needed from an operational standpoint. Such an approach is not desirable from an environmental or business perspective.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Entergy Services, Inc. strongly supports the creation of a limited use subcategory for electric generating stations auxiliary boilers that are used for supplying startup steam. These EGU auxiliary boilers typically operate for short periods of time, have limited capacity factors, and are often classified as "major sources" based solely on their location at a generating station. The infrequent operation of auxiliary boilers results in minimal emissions and makes the application of pollution controls and other requirements of the proposed regulation impractical.

It would be extremely difficult for an auxiliary boiler to meet an emission standard based on a 30-day rolling average since they do not run for an extended time period. In addition, operating merely for the purposes of testing would result in an estimated 10-20% increase in the number of hours an auxiliary boiler operates per year and would result in a corresponding increase in actual emissions. The proposed requirements are clearly impractical and excessive in light of the limited number of hours these relatively small boilers operate each year. Thus, Entergy recommends establishing a "limited use" subcategory for auxiliary boilers operating no more than 500 hours per year. This subcategory should be exempted from the requirements of the Proposed Rule except for reasonable recordkeeping requirements aimed at demonstrating annual operating hours.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: TEP believes EPA's approach for establishing MACT standards for auxiliary boilers is unnecessary and may actually have the unintended consequence of increasing emissions for the following reasons:

Due to the extremely limited use of these boilers (in TEP's case less than 0.1- percent of maximum annual heat input), hazardous air pollutant emissions from these boilers do not pose a threat to human health or the environment.

The cost to comply with the standards proposed by EPA would be excessive for these boilers especially when calculated on a "$/ton of pollutant removed" basis, again because of the limited use. While TEP has not conducted a detailed cost analysis, it is reasonable to conclude that for a facility regulated by the proposal, that operates for five hours or less, the cost associated with controlling the limited emissions from such a facility is not justifiable.

Demonstrating compliance with an emission standard through stack testing, or performing an annual tune-up to comply with the work practice standard would in our case require us to operate our auxiliary boilers more than we would otherwise, thereby resulting in more HAP emissions than would occur without a standard. EPA recognized the nonsensical nature of such a requirement by affirming in the proposed rule that “It would be inconsistent with the emission reductions goals of the CAA, and of section 112 in particular, to adopt requirements that would result in an overall increase in HAP emissions” [75 FR 32025].

CAA 112(h)(1) allows the EPA to establish a “design, equipment, work practice, or operational standard, or combination thereof” if in its judgment it is not feasible to prescribe and enforce an emission standard. For the reasons noted above, TEP believes that such an approach is appropriate for auxiliary boilers regardless of the fuel they burn. Due to the range of operating hours for limited use boilers, EPA should establish separate subcategories for limited use boilers, and set MACT standards for such equipment using the provisions of §112(d)(4), when appropriate. UARG, in their comments, provided the legal and rational basis under which EPA can and should create subcategories for limited use boilers, and use §112(d)(4) when appropriate. TEP believes that if EPA undertook a §112(h)(1) approach, they would conclude that the appropriate standard for limited use boilers approaching 10-percent of maximum annual heat input is a work practice for all fuel types as suggested in UARG’s comments.

However, for very limited use boilers (those whose heat input is less than 1-percent of the annual maximum) even an annual tune-up is not appropriate as pointed out above. For such very limited use boilers, EPA should establish a standard with no additional controls or requirements, other than monitoring annual hours of operation.

Comment: EPA Should Consider Other Subcategories for Industrial Boilers, Such As Utility Auxiliary Boilers .Section 112(d)(1) of the CAA allows the Administrator to distinguish among "classes, types, and sizes of sources" in establishing MACT standards. In providing EPA discretion to create subcategories, §112(d)(1) does not restrict subcategorization to cases where the "class", "type" or "size" factors affected HAP emissions. The provision merely requires EPA to establish regulations for each category or subcategory on the schedules set out in § 112. FCG appreciates EPA’s effort to create several subcategories in the proposed IB MACT rule. However, EPA should have created additional subcategories. A limited use subcategory should be created for lBs that are operated infrequently or at low capacity because of their specialized nature and use.

FCG members operate at least 6 natural gas-fired and 2 oil-fired auxiliary boilers that will be subject to the IB MACT rule because they are not steam generating units that produce electricity. These auxiliary boilers operate infrequently or in a warm standby mode and are used for startup and emergency operations to support the larger electric utility generating units. As a result, the HAP emissions from these auxiliary boilers are very low.

Under the proposed rule, the natural gas-fired auxiliary boilers are subject to work practice standards requiring an annual tune up. By contrast, the proposed IB MACT rule requires oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not produce environmental benefits.

FCG urges EPA to exempt these operations or create a limited use subcategory for auxiliary boilers subject only to limited work practice standards. The limited use subcategory could have a 10% capacity factor threshold based on 10% of the maximum hourly heat input of the boiler multiplied by 8760 hours per year. Alternatively, distillate oil-fired boilers that operate in a warm standby mode at less than 10mmBtu/hour a majority of the time would also be subject only to work practice standards.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: The level of emissions of HAPs anticipated from well-performing units will differ substantially depending on the fuel that is being combusted. Accordingly, NACAA agrees that the large subcategories identified by EPA in its ICI Boiler MACT proposal – coal-fired, biomass-fired, liquid-fired and gas-fired – are reasonable and warranted by the differences in technology and expected performance, given the nature of the fuel consumed. EPA acknowledges that the properties of the fuel being combusted contribute significantly to the level of HAP emissions.["[B]ased on recently obtained information, we now understand that factors other than the controls (e.g., waste mix and combustion conditions) affect HMIWI performance, and those emission reduction strategies must be accounted for in MACT floor determinations." 73 Fed. Reg. at 72,970, 72,975. See also 74 Fed. Reg. at 51,377-79] However, the proposed rules fail to properly address this fundamental point in several important ways.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type.

Comment: Industrial boilers should not be regulated in the same manner as electric utility boilers because of the differences in boiler size, fuel mix, application, design, operation, and the higher relative cost of emissions control. Although industrial boilers far outnumber electric utility boilers, industrial boilers produce a fraction of the steam that utility boilers produce and consume a fraction of the amount of fossil fuels that utility boilers consume. Industrial boilers also use their fuel more efficiently than utility boilers when the boilers produce both heat and power to support mill operations and do not experience the line losses that happen when electricity is transferred to utility customers. Industrial boilers in our industry also experience frequent load swings over the course of an operating day that utility boilers do not typically experience, and they typically burn more variable fuel types than utility boilers.

Response: See response to comment EPA-HQ-OAR-2002-0058-2795.1, excerpt 1 for additional subcategory for small municipal utilities or subcategorizing according to sector.

Comment: APPA also asks that EPA retain the limited use subcategory as finalized in the 2004 Boiler MACT rule. The D.C. Circuit Court decision vacating the 2004 rule did not undermine the justification set forth by EPA in support of a limited use subcategory. APPA members operate boilers in varying configurations, with some electric generating units used to backup primary units to ensure reliable electricity generation at all times. These backup units typically operate less than 10% of the time and in response to the scheduled and unscheduled downtime for primary units. These units may also be part of the standby capacity of a transmission network that must be reliably available to support the electric grid when need is determined by the transmission operator. These units must be operated periodically to ensure they will be reliably available upon demand to support the grid. APPA encourages EPA to adopt a limited use subcategory and/or exemptions that acknowledge the unique challenges associated with monitoring and measuring emissions from these sources. For instance, these units spend a considerable percentage of their time in periods of startup and shutdown during which control devices and/or monitoring equipment are not available or reliable. Compliance with the full-use MACT standard is not feasible for these units during these rapid and often unpredictable startup modes.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: In the document, "Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, commercial, and Institutional Boilers and Process Heaters – Draft (April 2010)," EPA does not address the impact of the proposed rules on the electric generating industry. Electric generating stations frequently have process (i.e., non-EGU) boilers used for supplying start-up steam. In many cases, because these units are sporadically used and have capacity factor limits, they are only identified as major sources due to their location at the EGU facility. Emissions from these units in the context of a power generating station are minimal. The proposed rule will have a large impact on the ability to operate these relatively small sources. The below table shows 2009 reported emissions from the electric generating unit (boiler) at Cheswick Generating Station compared with the emissions from the distillate oil-fired auxiliary (ICI) boiler.

[see pdf for table]

The proposed rule would impose the following requirements upon an Aux Boiler that has operated an average of 131 hrs per year (from 2005 to 2009):

* Install operate and maintain CO and oxygen CEMS and data acquisition and handling systems.
* Comply with a CO standard on a 30-day rolling average basis.
* Test annually for PM and dioxin/furan, and potentially test annually for HCl and mercury if compliance cannot be demonstrated through fuel-based methods. Assuming compliance can be demonstrated through fuel-based methods, the proposed rule would require at least 15 hours of performance testing per year (three 1-hour PM runs and three 4-hour dioxin/furan runs). If testing for all pollutants is required, the test duration increases to at least 24 hours per year. These times do not include start-up and stabilization. For the subject boiler at Cheswick, operating merely for the purposes of testing results in 10-20% increase in annual operating hours.

Previously, EPA chose to limit emissions from sources operated in non-continuous and infrequent manners by providing a category that restricts operation of these sources to a 10% annual capacity factor. This limited-use subcategory is still necessary and appropriate. In the final rule, EPA must classify ICI boilers by limited or unlimited use and these two subcategories should not be subject to the same requirements. Requiring emissions controls and onerous monitoring for infrequently operated sources is unduly burdensome and doesn't provide a significant contribution to emission reductions sought through this rule.

EPA should establish a Limited Use Category that is exempt from the emissions limits, CEMS, and stack testing requirements. Qualification for the Limited Use Category should be limited to 10% annual capacity factor.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Additional subcategories are needed for new source standards.

The proposed new source standards are unrealistic and, if left unchanged, could seriously endanger the nation's long-term prospects for growth in the manufacturing sector. Reports we hear from suppliers of boilers and air pollution control systems are that they will not be able to supply commercial guarantees to meet the proposed standards. Additional subcategories which focus on the regional fuel supplies (Powder River Basin, Illinois Basin, Central Appalachian, etc) are needed to allow future boilers to be installed across the nation. For example, the top performer used to set the HCl standard for new coal-fired boilers is a boiler which burn sub-bituminous coal, which inherently has much lower chlorine content than eastern coals. A facility on the east coast should not have to meet standards that can be met only by burning a fuel only obtained from hundreds if not thousands of miles away.

Response: See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 61 for additional subcategory based on regional fuel availability or geographic location.

Comment: An additional subcategory that EPA needs to establish is one for "limited use" units. Because limited use boilers do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers can vary significantly from those of a similar boiler operating in a steady state. A capacity utilization factor of 10% was chosen for the previous boiler MACT final rule as the best means of defining a limited use unit. This definition is equally appropriate for the current rule. Also, given the limited and sporadic operation of emergency and auxiliary boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should require work practices in lieu of emission limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Additionally, EPA's approach to subcategorizing the boilers and process heaters in the Gas 1 subcategory for purposes of establishing the potential floors in the preamble fails to account for units designed and operated to minimize emissions of oxides of nitrogen (NOx) to comply with state and federal permit limits. Units operated to keep NOx levels low will have higher emissions of CO. Thus, CO emissions from these units will be higher than boilers not designed or operated to keep their NOx emissions low and in compliance with permit limits. The CO floor level in the preamble for Gas 1 units ignores these design issues and any emission limits based on the potential CO floor level in the preamble would be difficult, if not near impossible, for these boilers to achieve while also meeting the required NOx permit limits. EPA has discretion to account for design characteristics when setting floors and has failed to do so.

Response: See response to comment EPA-HQ-OAR-2002-0059-2702.1, excerpt 68 for additional subcategory to distinguish between units with low NOx burners.

Comment: NESCAUM also recommends that EPA create a "limited use" boiler category, which should include units used for less than 200 hours per year or a boiler that comprises less than 10% of annual use with caveats to ensure that facilities do not aggregate many small boilers to avoid compliance with emission limits. These boilers may represent back-up or start-up boilers and should be exempted only if they use 15 ppm ultra-low sulfur content oil.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 17

Comment: In the original Boiler MACT, EPA included a limited use subcategory with less stringent emissions limits fitting the non-routine use of these combustion units, their low annual emissions and the resource thriftiness of the regulation as the cost of rarely used controls was avoided. The primary criterion to qualify for this limited use subcategory was having a federally enforceable annual average capacity factor of equal to or less than 10 percent (63.757 in 69 FR 55218).

EPA’s proposed Boiler MACT does not address limited use boilers, although at 63.7491(i) EPA would exempt “temporary” boilers that meet certain criteria including burning gas or liquid fuel, being mobile and being located on site for no more than 180 consecutive days. However, we operate a small number of boilers including gas and solid fuel-fired boilers that are run intermittently that would not qualify as temporary boilers; but these stationary units are operated infrequently or for short periods of time, and are maintained for service as emergency, back-up or replacement during maintenance outages of the primary boiler(s) or for winter supplemental heat supplies as needed. We believe EPA should develop a subcategory for these types of boilers and establish work practices to regulate their emissions instead of applying emission limits developed for or similar to those for boilers running continuously. The annual emissions of these units are low and installing and operating additional controls will not be feasible for this class of boilers. The MACT floor for these limited use boilers should be maintenance work practices because emission limitations are infeasible. We refer EPA to the extensive AWC and AF&PA technical discussions describing these types of units and their emission profiles and the legal and policy rationales for subcategorizing and managing the emissions of this class of boiler using work practices.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: NACAA supports the development of subcategories in MACT rule development, where such subcategories are based on meaningful differences in anticipated fuels and unit designs. Because NACAA's technical team identified significant differences in the anticipated emission profiles of wood-fired and coal-fired units, the NACAA Model Permit Guidance separated EPA's solid-fuel category into two subcategories, but, seeing no clear technical difference supporting EPA's limited use subcategory, deleted it.
In the vacated ICI Boiler MACT rule, EPA had established four categories – solid-fuel, liquid-fuel, gas-fuel and limited-use boilers. In the 2000 CISWI rule there was but one category – incinerators. The proposed ICI Boiler MACT rule has 11 subcategories while the proposed CISWI rule would have five subcategories. In support of the explosion in the number of subcategories EPA explains the differences in design between, for example, a coal-fired stoker boiler and a coal-fired PC boiler. However, large boilers do not come off an assembly line[56 Even mass-produced automobiles will exhibit design differences within and between models and manufacturers.] and last for up to 50 years. Almost every large boiler will have differences in design from every other large boiler. Even smaller boilers will have differences in design from small boilers produced by other manufacturers. Accordingly, it is insufficient to simply identify design differences. Where EPA seeks to establish additional subcategories it must explain why those differences matter and point to information in the record that supports its conclusion. In particular, we note that EPA's Boiler MACT categories are based on the nature of the fuel that is consumed while the proposed CISWI rule categories are based on the purpose of the combustion, not the fuel. EPA should identify a consistent rationale for establishing new subcategories.

Response: See preamble for discussion of new subcategories added since proposal and new justification in support of a limited use subcategory. The universe of affected boilers and process heaters is much larger and more diverse than the affected units under the CISWI rulemaking. EPA has the authority to determine the appropriate subcategories for each source category under Section 112 and the basis of subcategorization between multiple source categories do not need to be consistent. The Agency individually examines the available data and characteristics of each source category.

Comment: EPA's proposed CO standards for the Gas 2 subcategory and liquid fired boilers are not appropriate for limited use boilers.

Although variability impacts concern all boilers, certain types of boilers are affected more than others. These include limited use boilers such as boilers serving solely or primarily to provide heat during startups, boilers used to supply intermittent steam needs such as a boiler that is idle or shutdown except for periods when the facility is operating at peak loads, and boilers which are serving in a reserve capacity in which they are operating at minimal operating rates except in extraordinary circumstances. For example, a boiler which is used solely during facility startups could spend a large minority of operating time under cold startup conditions or highly variable load conditions. To illustrate, if a boiler is used solely for a startup use, then it may only be fired for 1 to 2 days. Load is dependent totally on the need of the facility and could (and probably will) vary from minimal firing to maximum firing over very short periods. As a result, regardless of the averaging period, the unit could never meet any of the CO limitations for any large boiler subcategory defined under this MACT since the unit will operate at a significant period with elevated CO concentrations.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: One additional subcategory that EPA needs to establish is one for "limited use" units. While the prior Boiler MACT rule treated units with average capacity factors of 10% or less separately, the proposed rule does not continue that approach. Instead, it presumes that limited use units are just like those operated full-time which burn a similar fuel. Limited use sources are like temporary boilers (which are exempt from the rule) in that they operate intermittently and for shorter periods of time (e.g., small package boilers that are only used during mill outages, a backup boiler that runs when other units are being fixed, or a peaking unit used to supplement electric generation during particularly hot summer days). Compared to most boilers, these units spend a far greater percentage of their time starting up and shutting down. (The impact of meeting the proposed limits during periods of startup and shutdown are discussed in greater detail in section XVIII of these comments.) As a result, their emissions profiles differ from sources which operate in efficient steady-state manners. For example, they are likely to experience higher CO levels as the boiler heats up due to incomplete combustion. Similarly, many pollution control technologies are either difficult to use or ineffective during startup and shutdown periods and would be cost prohibitive to install and use for only short periods of time during a year. These are just the sort of "class" and "type" distinctions which merit consideration for subcategorization under §112(d)(2).
Because limited use boilers do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers can vary significantly from those of a similar boiler operating in a steady state. 75 FR 32023 ("Combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit's load (steam production) decreases."). Given their short run times, there are also technological limitations on how effectively emissions from these units can be controlled, particularly for organic HAP emissions. See Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 67 (February 25, 2004) ("[W]e could not identify any control technologies that would reduce organic HAP emissions [for limited use boilers]. Therefore, while larger units may emit more than smaller units, we have not identified any appropriate technology or method that could be used to reduce organic HAP emissions."). Finally, since "limited use boilers, when called upon to operate, must

respond without failure and without lengthy periods of startup," National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 FR 55218, 55232 (September 13, 2004).a significantly larger percentage of their annual operation will be devoted to maintenance and readiness testing than other commercial, industrial, or institutional boilers. These differences justify the creation of a subcategory for limited use boilers and process heaters.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: In March of this year, EPA provided a similar subcategory in its final rule promulgating national emission standards for existing compression-ignition reciprocating internal combustion engines ("CI RICE") with a site rating of less than or equal to 500 brake horsepower. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 FR 9648 (March 3, 2010).
In that Rule, EPA recognized that stationary existing CI RICE should be divided into non-emergency and emergency categories "in order to capture the unique differences between these types of engines." Id. at 9650. Like the limited use boilers described in EPA's September 13, 2004 rule, EPA recognized that these emergency CI RICE are required to operate infrequently and for relatively short periods of time and must be kept in working order during prolonged periods of time when they are not operating.
EPA cited as justification for its emergency unit subcategorization an earlier memorandum titled Subcategorization and MACT Floor Determination for Stationary Reciprocating Internal Combustion Engines ?500 HP at Major Sources, Docket No. EPA-HQ-OAR-2008-0708-0006 (January 21, 2009). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 74 FR 9698, 9705 (March 5, 2009). This memorandum, in turn, incorporated by reference the rationale found in the memorandum Subcategorization of Stationary Reciprocating Internal Combustion Engines ?500 HP, Docket No. EPA-HQ-OAR-2005-0030-0012 (May 15, 2006), which enumerated four reasons for creating a subcategory for emergency CI RICE:
1. Emergency use units are used when electric power from the local utility is interrupted or becomes unreliable. The duration of the power outages is entirely beyond the control of the source, and, when they do occur (except in the case of a major catastrophe) they rarely last more than a few hours, often only a few minutes.
2. Emissions from these units are expected to be low on an annual basis; emissions occur only during emergency situations or for a very short time to perform maintenance checks and operator training. State and local regulators generally have not required emission controls for emergency power/limited use units.
3. Add-on catalytic control devices that are most applicable to reduce HAP from stationary RICE would be less effective on an annual basis for emergency use units, since emergency use units

generally operate for brief periods. Therefore, a greater percentage of the emergency use units' operation, as compared to operation of peaking or baseload engines, will occur during catalyst warm-up, when the catalyst's effectiveness will be lower.
4. Emergency use units operate for very few hours per year. A survey conducted by the California Air Resources Board indicated that emergency engines are operated about 30 hours per year. Also, the National Fire Protection Association requires 30 minutes per week (27 hours per year) to maintain and test emergency engines. The recently finalized Airborne Toxic Control Measure in California allows districts to approve up to 100 hours per year for maintenance and testing of emergency engines.
Id. at 5-6. While these criteria focus on an "emergency use" subcategory, it is important to note that the limited duration of the use, not the purpose for using the RICE is the key issue. For example, the same rule also creates a subcategory for "black start" engines (engines used to start a turbine generator), which operate during both "emergency and high demand days." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 FR 55218 at 9662.

These same criteria justify the establishment of a limited use boiler MACT subcategory. First, limited use boilers are put into service only during maintenance outages, unexpected failures of the main boiler, or "when electric power from the local utility is interrupted or becomes unreliable" and some of these events are "entirely beyond the control of the source." Id. at 5. Second, because of their limited use during the year, "[e]missions from these units are expected to be low on an annual basis." Id. Third, for this same reason, a greater percentage of a limited use boiler or process heater's annual operations will be during startup and shutdown, when emissions controls are less effective. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 FR at 32023. Finally, like emergency CI RICE, limited use boilers operate for only a small portion of the year, typically "10 percent of the year or less." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 FR at 55232.
Like emergency and black start CI RICE, limited use units should be placed into a subcategory that recognizes the unique challenges that would be faced monitoring and controlling emissions from these units.

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 163

Comment: The unique operating characteristics of limited use boilers, there are practical reasons for creating a limited use subcategory. As noted by Judge Williams in Sierra Club v. EPA, "Section 112(d)(1) authorizes the Administrator to 'distinguish among classes, types, and sizes of sources within a category or subcategory' . . . . [O]ne legitimate basis for creating additional subcategories must be the interest of keeping the relation between ‘achieved’ and ‘achievable’ in accord with common sense and the reasonable meaning of the statute. Sierra Club v. EPA, 479 F.3d 875, 884-85 (D.C. Cir. 2007) (Williams, J., concurring).

Without subcategorization for limited use boilers, these infrequently operated units will need to comply with the same emission limits set by units that operate on a continuous basis. As noted above, “combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit’s load (steam production) decreases.” National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 FR at 32023. Limited use boilers will therefore be operating for a significantly greater percentage of their time during periods of inefficient operation.

While EPA has already attempted to address this problem through the current MACT floor analysis by addressing the reduced efficiency of load-following units through allowances for variability, (See MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 9-10 (April 2010)) this problem is further amplified for limited use boilers, which EPA did not address in its MACT floor analysis, due to EPA’s decision to include periods of startup and shutdown in determining compliance with MACT. As found by EPA, this was justified because “the standards that we are proposing are daily or monthly averages. Continuous emission monitoring data obtained from best performing units, and used in establishing the standards, include periods of startup and shutdown. Boilers, especially solid fuel-fired boilers, do not normally startup and shutdown more the [sic] once per day. Thus, we are not establishing a separate emission standard for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards.” Id. at 32013. Continuous emission monitoring data is not available for all pollutants in the database. To the extent that emission limits are based on stack test data that does not consider SSM events, emission information based on an operator’s knowledge and engineering calculations can be used to incorporate SSM variability into the MACT Floor analysis. Moreover, EPA found that “[p]eriods of startup, normal operations, and shutdown are all predictable and routine aspects of a source’s operation.” Id. Neither of these findings reasonably applies to limited use boilers. First, as discussed above, these boilers cannot practically make measurements over a monthly average given their limited utilization. Second, emergency and backup uses are by definition neither predictable nor routine.

By their very nature, limited use boilers must spend a larger percentage of time in startup, shutdown, or other reduced-efficiency operating conditions than either base-loaded or load-following units. EPA should not require limited use boilers to comply with standards set by the best operated of these more efficient units.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: EPA also describes a subcategory of small boilers of all kinds. That subcategory, for sources burning any fuel at a rate less than 10 MMBtu per hour, while purportedly based on "size" of source, is justified by the Agency only on assertions that "the standard reference methods for measuring emissions of mercury, CO..., D/F, HCl ... and PM...are generally not able to accurately sample small diameter (less than 12 inches) stacks. ... Units that have capacity below 10 million MMBtu per hour generally have [such small diameter] stacks...[a]lso, many existing small units do not currently have sampling ports and a platform." 75 Fed. Reg. 32,024. In fact, this distinction is really one of costs – EPA further asserts that the costs to demonstrate compliance with technology based limits at these units "would have a significant adverse effect on these facilities" which EPA says would vary by facility size (i.e., smaller facilities would be less likely to be able to bear the costs). Id.

Comment: EPA has developed subcategories of boilers under the proposed rule by fuel type, and in some cases, boiler type. We believe that it is appropriate to develop subcategories based on these criteria, as it recognizes the differences in boiler design, operation, and emissions. For example, a solid-fired unit having the combustion occur on a grate has different challenges for optimizing the fuel-air ratio than that of a unit in which the combustion occurs in suspension. Combustion on a grate is subject to piling and smoldering that cannot simply be controlled by increasing the amount of excess air, yet can cause CO emissions to spike unexpectedly.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type.
See response to comments EPA-HQ-OAR-2002-0058-2916, excerpt 2 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 54 for subcategories for based on design type, and for cyclone, firetube, and hybrid watertube-firetube boilers.

Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 145

Comment: EPA has broad discretion to establish subcategories of sources. Section 112 provides EPA with explicit authority "to establish subcategories under this section, as appropriate." § 112 (c)(1); see also §112 (c)(5) ("… the Administrator may at any time list additional categories and subcategories of sources[.]"). Indeed, § 112 establishes a presumption in favor of the creation and modification of categories and subcategories in the course of the Agency's regulatory program, by mandating that EPA "shall from time to time, but no less often than every 8 years, revise, if appropriate, in response to public comment or new information, a list of all categories and subcategories of major sources[.]" §112(c)(1).
Section 112(c)(1)'s language empowering EPA "to establish subcategories … as appropriate" without the inclusion of criteria limiting the Agency's ability to do so confers a broad grant of authority. The D.C. Circuit previously has interpreted the inclusion of the phrase "as appropriate" in a more limiting statutory mandate as conferring substantial discretion. Consumer Federation of America v. U.S. Dept. of Health and Human Services, 83 F.3d 1497 (D.C. Cir. 1996).
At issue was a provision of the Clinical Laboratory Improvement Amendments of 1988, which directed HHS to establish qualifications for laboratory technicians that "shall, as appropriate, be

different on the basis of the type of examinations and processes being performed[.]" Id. at 1503. The court found that, even though the statutory mandate at issue – using the word "shall" – was phrased in a way generally interpreted to impose a mandatory duty to differentiate qualifications based on different types of tests, the inclusion of the words "as appropriate" removed the mandatory nature of this provision and introduced a significant amount of agency discretion in its implementation. Id. To hold otherwise, concluded the court, would treat the statutory terms "as appropriate" as mere surplussage, thereby violating a basic canon of statutory construction. Id. In the CAA context, the mandate conferred by §112 to establish subcategories "as appropriate" similarly provides substantial discretion for EPA to create subcategories on any reasonable basis. Nothing in the Act or applicable caselaw suggests otherwise.

While EPA has nearly unfettered discretion to create subcategories as appropriate, the CAA provides ample authority for EPA to distinguish among groups of sources within a source category or subcategory in setting a MACT standard. The statute provides that EPA "may distinguish among classes, types and sizes of sources within a category or subcategory" when establishing MACT standards. 42 U.S.C. § 7412(d)(1) (emphasis added). Congress' use of the broad terms "class," "type," and "size" shows that EPA is intended to have broad discretion in the appropriate factors that warrant distinguishing among sources, and EPA's proposed subcategories fall squarely within the meaning of "types" and "sizes."

It is a well-established canon of statutory construction that courts "give the words of a statute their ordinary, contemporary, common meaning, absent an indication Congress intended them to bear some different import." Williams v. Taylor, 529 U.S. 420, 431, 120 S.Ct. 1479, 1487-88, 146 L.Ed.2d 435 (2000). Accordingly, we turn to the standard definitions of "class," "type" and "size." Webster's Third New International Dictionary Unabridged (1993) defines "class" to mean "a group, set or kind marked by common attributes or a common attribute." It defines "type" as "qualities common to a number of individuals that serve to distinguish them as an identifiable class or kind," further clarifying that "'[t]ype', 'kind' and 'sort' are usually interchangeable" and that "'kind' in most uses is likely to be very indefinite and involve any criterion of classification whatsoever." To the extent that EPA may distinguish among sources within a category or subcategory on the basis of "any [reasonable] criterion of classification whatsoever," and may create subcategories as appropriate, the CAA strongly supports EPA's authority to create subcategories of industrial boilers as proposed.

Response: The EPA thanks the commenters for their support and recognonition of EPA's authority to create subcategories based on legislative history, case law and the CAA.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 146

Comment: The legislative history makes clear that Congress intended EPA to distinguish among classes, types and sizes of sources under three core circumstances: when differences among sources affect (1) the feasibility of air pollution control technology; (2) the effectiveness of air pollution control technology; and (3) the cost of control.

The Senate Report clarifies that the Administrator should:
“take into account factors such as industrial or commercial category, facility size, type of process and other characteristics of sources which are likely to affect the feasibility and effectiveness of air pollution control technology. Cost and feasibility are factors which may be considered by the Administrator when establishing an emission limitation for a category under section 112. The proper definition of categories, in light of available pollution control technologies, will assure maximum protection of public health and the environment while minimizing costs imposed on the regulated community. However, in limited circumstances where a group of sources may share the characteristics of other sources in the category, the Administrator may establish subcategories for such sources.” S. Rep. No. 228, 101st Cong., 1st Sess 166.
Thus, in the view of the Senate, the standard for establishing categories and subcategories is essentially the same, although the Administrator is cautioned not to make too rampant use of subcategories.
The House Report similarly provides: “EPA may distinguish among classes, types and sizes of sources within a category or subcategory. . . . In the determination of MACT for new and existing sources, consideration of cost should be based on an evaluation of the cost of various control options. The Committee expects MACT to be meaningful, so that MACT will require substantial reductions in emissions from uncontrolled levels. However, MACT is not intended to require unsafe control measures, or to drive sources to the brink of shutdown.” House Rep. No. 101-490, Part 1, at 328.
In sum, while Congress intended the MACT program to achieve significant emissions reductions, it also intended EPA to be cognizant of the costs of control, and to ensure that the program did not cause significant economic hardship. One primary mechanism for achieving this goal is through the use of subcategories; subcategorization enables the Agency to account for the fact that distinctions among classes, types and sizes of sources may have a very real impact on the feasibility of a given control technology, the effectiveness of that control technology, and the cost of control.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA’s authority to create subcategories.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 147

Comment: The only case to interpret the “classes, types and sizes” language supports this interpretation. Sierra Club v. Costle, 657 F.2d 298 (D.C. Cir. 1981), recognized the broad discretion this language confers on EPA to create what in effect are subcategories of sources with differentiated emission standards. This decision interpreted identical statutory language found in the New Source Performance Standards (NSPS) provisions of § 111 of the CAA. Under the “classes, types and sizes” language, the Sierra Club court upheld a variable NSPS SO2 reduction requirement that was tied to a source’s existing SO2 emissions levels which, in turn, depended on the sulfur content of the facility’s fuel. The Court noted that “[t]he required finding

that must underlie a variable standard is much broader than a mere determination that uniformity is not achievable. Rather, EPA has the discretion to vary the standard upon finding that such a departure (from uniform control) does not undermine the basic purposes of the Act." Id. at 321. On this basis, the Court expressly upheld EPA's subcategorization of coal-fired power plants based on the sulfur content of fuel, finding that "[c]ertainly the text of the statute nowhere forbids a distinction based on sulfur." See id. at 319. More generally, the Sierra Club decision confirms EPA's discretion to set differentiated emissions standards for groups of sources within a category – i.e, for subcategories – even in instances where the strictest standard may be achievable by all sources.
The Report further provides that "Nothing in this language authorizes the establishment of a category based wholly on economic grounds, nor is there any implication that individual facilities may be granted categorical waivers … based on assertions of extraordinary economic effect." Id. In other words, the cost of control is an appropriate basis for distinguishing among sources so long as it is not the only basis that distinguishes among those sources.
The Court's analysis in Sierra Club has obvious relevance to an analysis of the authority granted to EPA through CAA § 112. Section 112 employs the same language as Section 111 in defining when EPA may promulgate distinct emission standards for sources within a category or subcategory. The Supreme Court consistently has held that "when administrative and judicial interpretations have settled the meaning of an existing statutory provision, repetition of the same language in a new statute indicates, as a general matter, the intent to incorporate its administrative and judicial interpretations as well." Bragdon v. Abbott, 524 U.S. 634, 645 (1998). Therefore, § 112, which adopted § 111's terms almost ten years after the D.C. Circuit issued the Sierra Club decision, must be understood to carry the settled meaning given to those terms by Sierra Club.

Response: See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 61 for additional subcategory based on regional fuel availability or geographic location.
See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Comment Excerpt Number: 148

Comment: EPA's past practice has been consistent with this interpretation of the Act. The Agency has subcategorized sources in numerous industrial categories. From this experience, it is possible to distill several principles that have guided the Agency's decision making with regard to creation of subcategories. First, EPA has determined that subcategorization is appropriate where sources use different processes, and those processes result in different types or concentrations of uncontrolled HAPs. Here, for example, the suite of HAPs emitted by solid-fueled boilers differs from that emitted by liquid-fueled boilers, which in turn differs from that emitted by gas-fueled boilers. For example, the types of metals emitted by solid-fueled boilers differs from the types of metals emitted by liquid-fueled boilers– and gas-fueled boilers typically emit little metals, but may emit more organic HAPs. See 68 Fed. Reg. at 1670. Thus, subcategorization based on fuel type is appropriate because the different types of boilers emit different types of HAPs.

Response: The EPA disagrees with commenter's suggestion to further subcategorize by fuel type. Although the EPA recognizes the variation in emissions between different fuel types, many units burn a mixture of fuel types and EPA determined that its combustor design-based classifications for organic HAP pollutants appropriately distinguish between operating and design characteristics of boilers that burn a single fuel type. The EPA also considers that variability has been incorporated into the MACT floor analysis because the emission limits developed for the MACT floor level of control incorporate boilers using various fuels and variations of control devices.

Comment: The Agency has subcategorized sources based on size, where size differences affect the performance of control technologies, such as where more frequent start up and shut down makes it more difficult for smaller sources to maintain the same level of control as larger sources. That is also the case here. There are fundamental differences in the design of small boilers, as compared to large boilers. Moreover, smaller units often are used in swing load mode, whereas larger units more typically are base-loaded. These smaller boilers have more frequent start ups and shut downs that impact the performance of control technology, and hence the achievability of the standard. Thus, subcategorization of boilers based on size – or infrequent utilization – also is consistent with EPA's past precedent and is appropriate because of the impact of these factors on the ability of these sources to maintain the same level of control as larger sources.

Response: See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.

Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 150

Comment: Furthermore, the Agency has subcategorized sources where differences among sources affect the applicability of control technology. For example, EPA created subcategories in the 1999 polyether polyols production MACT standard, finding that "[s]ubcategorization was necessary due to the distinctively different nature of the epoxide and THF processes and its effect on the applicability of controls." Similarly, in the 1998 flexible polyurethane foam production MACT standard, EPA found that "[s]ubcategorization was necessary to reflect major variations in production methods, and/or HAP emissions that affect the applicability of controls." Based on similar rationales, EPA created subcategories in the Group I polymers and resins MACT and the primary aluminum production MACT, and proposed to create subcategories in the polyurethane foam production MACT. Here, for example, fabric filters may be an appropriate control technology to capture metals from coal-fired boilers, but are not appropriate for use on oil-fired boilers because the soot blinds the bags of the fabric filter, and is also a fire hazard. Thus, subcategorization based on fuel type is appropriate because the type of fuel affects the applicability of control technology.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 61

Comment: Imposing emission limits on liquid-fired boilers and process heaters, versus work practice requirements for most gas-fired boilers and process heaters, will tend to drive sources to replace liquid-fired units with natural gas-fired units. However, some facilities do not have this option. For instance, some facilities in Alaska and those on isolated islands (e.g., Hawaii and the Virgin Islands) have no option to use imported gaseous fuels rather than liquid fuels to meet their fuel balance needs and in most of these cases, even the choice of liquid fuels is quite restricted.

Refineries and crude loading facilities located on islands or remote locations, such as Alaska, have unique configurations and constraints that mainland refineries and loading facilities do not. One of the key constraints is that islands and remote locations cannot physically access natural gas pipelines. This makes the burning of liquid fuels (produced on site or purchased locally) an unavoidable part of doing business in those locations, as EPA observes in the rule preamble. Moreover, the dual fired heaters used at many island/remote facilities are a very different design than EPA apparently contemplated in establishing subcategories and this design also affects the combustion chamber design.

In these situations, facilities are also limited in what liquid fuels they can use. They may have only one practical supplier of fuel oil. For refineries that is typically the refinery itself. The HAP metals and chlorine content of those liquid fuels is set by the refinery crude slate and process. These facilities do not have an option to seek out lower metal or chloride fuels and must use what is produced or available locally. In his concurring opinion in the Brick MACT case, Judge Williams stated that EPA's ability to create subcategories for sources of different classes, size, or type (CAA section 112(d)(1)) may provide a means out of the situation where the floor standards are achieved for some sources, but the same floors cannot be achieved for other sources due to differences in local raw materials whose use is essential. Such an approach would allow EPA to address the special problems of facilities in remote locations where access to natural gas and alternate liquid fuels is non-existent or extremely limited.

Because of their very different properties, fuel oils cannot be combusted in the same burner elements as gas fuels. They can be simultaneously combusted in a burner equipped with both oil and gas burner elements, which changes combustion dynamics and is an operating mode not apparently recognized by EPA in the development of this proposal.

At refineries without natural gas supplies, fuel gas produced by units like Fluid Catalytic Cracking units and Delayed Coking units can constitute up to 60% of the total refinery fuel gas production. When those units experience upsets or planned or unplanned shutdowns or slowdowns, fuel oil usage will increase to balance the energy supply. Slowdowns can occur for a variety of reasons, such as unfavorable economics, maintenance or fuel quality limitations. Refineries and other facilities typically have planned shutdowns for major maintenance of individual units, which can occur on 3 to 6 year intervals, depending on the unit. Unplanned unit shutdowns occur due to unpredictable unit malfunction. Whether planned or unplanned, shutdowns or slowdowns can greatly affect the amount of fuel gas and fuel oil that must be burned to maintain an energy balance.

In addition to shutdowns and slowdowns, fuel gas producing units can experience daily variations in their gas production by as much as 20% in one hour. One example of this is Delayed Cokers, which are batch processes. Delayed Cokers have cycle times between 12 and 18 hours, and the amount of gas produced varies by time in the cycle. Another example is daily variation in fuel gas production due to ambient temperature differences between night and midday, particularly for warm temperature climates such as the Caribbean or Hawaii.

Other operational factors can also significantly change the amount of fuel gas available. For example, feedstock quality changes or feed rate changes to gas producing units will affect the amount of gas produced. The effect is that the facility must switch from gas to oil, or vice versa, to balance the fuel needs of the facility.

There is a particular problem with meeting CO limits for refineries without natural gas access. A critical factor in low CO operation is a stable, consistent operation that maintains combustion conditions conducive to complete combustion. While refineries are typically dynamic operations and may experience rate turndowns, island and remote location facilities have operational issues relating to fuel oil burning that go well beyond typical refineries. For the reasons discussed above, large daily and episodic variations in fuel gas production, gas composition and heating value, and fuel demand changes results in large variations in fuel oil consumption for each fuel-oil burning unit. These swings are made manually by switching burners and/or burner tips from gas to oil or vice-versa and then manually adjusting excess air. One or more burners can be switched over a period of hours to adjust the fuel balance. Switching burners from oil to gas requires step processing to prevent surging the refinery fuel gas system pressure and releasing fuel gas into the flare system. This is not a precise science and the nature of these manual adjustments makes it difficult to optimize oxygen levels in the heater or boiler around a 3% excess oxygen target during this switching. These changes can also result in flame impingement on the heater tubes or in the boiler firebox. The result will be higher CO and less efficient combustion. EPA failed to take these types of variations into account in setting the MACT floors for liquid burning units. For CO for example, EPA relied on stack test data as opposed to CEM data to come up with a proposed limit. A stack test will not reflect burning condition variations due to fuel swings as facilities that were tested were not in island/remote locations and will hold a unit steady during the test.

Subcategorization has been used to address special situations involving small groups of facilities and that approach could be used here to address this concern. For instance, in the stationary combustion turbine NESHAP, a much more homogeneous source category than boilers and process heaters, eight subcategories were established, including a subcategory to address stationary combustion turbines operated on the North Slope of Alaska (defined as the area north of the Arctic Circle (latitude 66.5° North)). The special situation at remote refineries has also been addressed in the Part 60 rules. For instance, subpart KKKK of part 60 establishes a separate sulfur content limit for distillate used for power generation turbines in Hawaii.

Recommendation: Create a subcategory for boilers and process heaters in locations without access to natural gas and with limited access to alternate liquid fuels and only apply work practice requirements to boilers and process heaters in such locations.

Response: See preamble for discussion of the new non-continental subcategory.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 105

Comment: The data fail to include a representation of the many units that run in standby mode or at significantly turned down rates most of the time. This situation is common for standby and emergency boilers, boilers whose demand varies substantially by season, process heaters where demand varies significantly with changing process operations, and process heaters which have high demand only intermittently. For instance, in some catalyst operations, feed heaters operate at very low rates when the catalyst is fresh, but ramp up to higher rates as the catalyst ages, perhaps over a period of years. Other process heaters may operate at very low rates except during process startups when certain special operations occur (e.g., catalyst regenerations) or for certain process line-ups or production of certain products.

Response: See the preamble for revisions made for limited use boilers.

Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 1

Comment: Luminant has 18 distillate oil- and natural gas- fired auxiliary boilers used for startup that will be directly impacted by this rule. These auxiliary boilers have heat input ratings from approximately 20 mmBtu to 480 mmBtu and perform startup steam functions, including providing sealing steam to the primary turbine and boiler feed pump turbine glands which prevent air leakage into, and steam leakage from, the turbine cylinders. Once the main utility boiler can reliably provide this sealing steam,the auxiliary boiler can be removed from service. Therefore, the auxiliary boilers have a very limited use and are in a transitional state of operation most of that operating time.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Affiliation: Whirlpool Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-2403.1
Comment Excerpt Number: 4

Comment: “Stand-by” Boilers
A Whirlpool facility has a Gas 1 stand-by boiler that is normally used for short periods, once or twice a year. This unit serves as a back-up for the other units. In 2009, the unit had zero hours of operation. Whirlpool requests an exemption to the rule for Gas 1 boilers in this 10 to 100 MMBtu range when used less than 10% of the time in a calendar year. We request that these units be governed under the same rules as the less than 10 MMBtu boilers as long as they qualify as a stand-by unit.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 4

Comment: Section 112(c) of the CAA authorizes EPA to establish a list of all categories and subcategories of major sources, “as appropriate,” and § 112(d) provides that EPA “may distinguish among classes, types, and sizes of sources within a category or subcategory in establishing” MACT standards. 42 U.S.C. § 7412(c), (d). EPA has exercised this broad authority and has proposed to subcategorize boilers and process heaters by unit design and further by combustion systems. See 75 Fed. Reg. 32,006, 32,017 (June 4, 2010).

Luminant supports EPA's subcategorization based on both unit design and on combustion method. EPA correctly recognizes that "there are significant design and operational differences between units that burn coal, biomass, liquid, and gaseous fuels," and that "[b]oiler systems are designed for specific fuel types and will encounter problems if a fuel with characteristics other than those originally specified is fired." Id. Further, EPA is correct that "because different types of units have different emission characteristics which may influence the feasibility or effectiveness of emission control, they should be regulated separately, (i.e., subcategorized)." Id. EPA's stated reasons for subcategorizing also support development of at least two additional subcategories, as discussed below.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 5

Comment: EPA should include a subcategory for low capacity startup boilers. Luminant has a number of low capacity, auxiliary startup boilers that would be impacted by this proposed rule. For example, Luminant has two distillate-fired boilers that have each averaged approximately 75 annual operating hours for the past 10 years. The proposed subcategories do not account for the unique characteristics of these boilers. Without such a subcategory, the NESHAP would require low-capacity-factor boiler operators to expend inappropriately large amounts of time and expense with an inversely proportional actual reduction in emissions. And, in fact, in some cases, merely completing the required testing would add 20 to 30% to the total emissions for that boiler in a year. That is counterproductive to achieving emissions reductions and, because much of the steam generated during the required testing would be wasted, counter to good energy policies.

EPA has already determined that these auxiliary ("limited use") boilers should have their own subcategory. See 68 Fed. Reg. 1660, 1670 (Jan. 13, 2003) (original proposed rule). Specifically, EPA stated that
[a] review of the information gathered on boilers also shows that a number of units operate as backup, emergency, or peaking units that operate infrequently. Back-up or emergency units only operate if another boiler that is the regular source of energy or steam is not operating (for example due to a shutdown for maintenance or repair). Peaking units operate only during peak energy use periods, typically in the summer months. The boiler database indicates that these infrequently operated units typically operate 10 percent of the year or less. These limited use boilers, when called upon to operate, must respond without failure and without lengthy periods of startup. While these are potential sources of emissions, and it is appropriate for EPA to address them in the proposal, the Agency believes that their use and operation are different compared to typical industrial, commercial, and institutional boilers. Consequently, we decided that such limited use units should have their own subcategory.Id. (emphasis added). Yet, although both the old and new rule recognize the special circumstance of boilers with heat input

capacity of less than 10 mmBtu/hr, the new rule does not similarly recognize the inefficiency of regulating limited-use boilers, which have very small capacity factors. Cf. 69 Fed. Reg. 55,218, 55,268 (Sept. 13, 2004) (defining “limited use” subcategories to include boilers or process heaters with a rated capacity of greater than 10 mmBtu/hr and “a federally enforceable annual average capacity factor of equal to or less than 10 percent.”). EPA should add a subcategory for low capacity startup boilers such as those operated by Luminant.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Mary Graham
Commenter Affiliation: Charleston Metro Chamber of Commerce
Document Control Number: EPA-HQ-OAR-2002-0058-2732.1
Comment Excerpt Number: 9

Comment: An additional subcategory that EPA needs to establish is one for "limited use" units. Because limited use boilers do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers can vary significantly from those of a similar boiler operating in a steady state. A capacity utilization factor of 10% was chosen for the previous boiler MACT final rule as the best means of defining a limited use unit. This definition is equally appropriate for the current rule. Also, given the limited and sporadic operation of emergency and auxiliary boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should require work practices in lieu of emission limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 13

Comment: Limited use units are those units that operate a very limited amount of time on an annual basis, i.e., less than 10 percent or 20 percent of the time annually. The proposed rule does not address limited use units. In essence, an affected source that operated a limited amount of time would have to meet the same limits as a source that operates year-round. EPA addresses the rationale for and development of work practice standards for small boilers and process heaters [<10 million British thermal units per hour (MMBtu/hr) heat input]. EPA cites the technological and economic limitations and impacts of imposing emission limits, stack testing requirements, etc., on these small boilers.

Many of these same arguments are applicable to limited use units. Although some limited use units may be more amenable to stack testing, many of these units are not equipped with stack sampling facilities, and for many it would not be technologically feasible to stack test (i.e., sampling ports would not meet minimum criteria; platforms would not be able to be installed without significant cost, etc.). Also, due to their limited operation (presumably as a backup to another boiler), it would be difficult to schedule a stack test on these units. CO and PM CEMS would be very costly to install for little use or benefit.

The FSI therefore requests that work practice standards be set for limited use units, in the same manner as for small units.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Donald R. Schregardus
Commenter Affiliation: Department of Defense
Document Control Number: EPA-HQ-OAR-2002-0058-2763.1
Comment Excerpt Number: 15

Comment: It is recommended that EPA reassess the establishment of a CO limit for oil-fired boilers, especially existing boilers, and base the MACT floor on a more representative subset of boilers currently in operation that takes into account the potential background levels of CO in the combustion air.
As proposed, all new oil-fired boilers and all existing oil-fired boilers greater than 10 MMBtu/hr are subject to emission limits. The final rule should differentiate requirements between emergency and nonemergency oil-fired boilers. Emergency boilers, like emergency generators, operate primarily during routine maintenance/testing. In many cases, subjecting emergency boilers to the same testing and monitoring requirements as nonemergency boilers to demonstrate compliance with emission limits would increase their operating time and result in little, if any, air quality benefit.

The hospital at a DoD facility in Alaska has three 19 MMBtu/hr oil-fired boilers that produce steam to heat the facility in the event of a utility outage. Because the military installation is a major source facility, the hospital's emergency boilers are subject to the major source version of the proposed rule. The three oil-fired boilers are permitted (Title V) to operate 600 hours, combined, during any consecutive 12-month period. Each boiler is subject to and complies with New Source Performance Standards, 40 CFR §60, Subpart Dc. The average consecutive 12-month run time during 2010 is 14 hours per boiler (emergency plus maintenance/testing). A conservative estimate for stack testing one boiler is eight hours. The annual stack test alone would increase each boiler's average consecutive 12-month run time from 14 hours to 22 hours. With added monitoring and/or need to retest, it is feasible that the rule would cause each boiler to double its annual run time.

Establish a subcategory for emergency use, oil-fired boilers and establish work practice standards in lieu of application of the currently proposed emission limits for these units. Similar to the alternative requirements for emergency utility equipment within the Stationary Reciprocating Internal Combustion Engine (RICE) NESHAP, enforcing work practice standards for emergency use boilers within the Boiler MACT would promote efficient operating conditions while minimizing the risk of increasing operating time and emissions.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 30

Comment: In this proposal, sources have been subcategorized by fuel fired and, for solid fuels, further subcategorized by equipment design. Subcategorization has been used very sparingly for other purposes (e.g., to distinguish <10 MMBTU/hr boilers and process heaters from >10 MMBTU/hr units). Many special issues that could have been dealt with by subcategorization have, therefore, not been addressed and cause many problems in the proposal. For instance by not subcategorizing boilers and process heaters below 1 or 5 MMBTU/hr as a separate subcategory, the proposal would wastefully and for no benefit make very small units subject to the tune-up requirements. We have tried to point out in our comments situations where further subcategorization would be helpful and we suggest the Agency greatly increase the use of this approach to address those situations (e.g., limited use; turndown, startup and shutdown, faculties with no access to natural gas).

It is worth noting that the Stationary Combustion Turbine MACT has successfully used subcategorization to address special situations. That rule established eight subcategories of turbine (a much more homogeneous source category than boilers and process heaters0 as follows: (1) Emergency stationary combustion turbines, (2) stationary combustion turbines which burn landfill or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis or where gasified MSW is used to generate 10 percent or more of the gross heat input to the stationary combustion turbine on an annual basis, (3) stationary combustion turbines of less than 1 MW rated peak power output, (4) stationary lean premix combustion turbines when firing gas and when firing oil at sites where all turbines fire oil no more than 1000 hours annually (also referred to herein as ??lean premix gas-fired turbines“), (5) stationary lean premix combustion turbines when firing oil at sites where all turbines fire oil more than 1000 hours annually (also referred to herein as ??lean premix oil-fired turbines“), (6) stationary diffusion flame combustion turbines when firing gas and when firing oil at sites where all turbines fire oil no more than 1000 hours annually (also referred to herein as ??diffusion flame gas-fired turbines“), (7) stationary diffusion flame combustion turbines when firing oil at sites where all turbines fire oil more than 1000 hours annually (also referred to herein as ??diffusion flame oilfired turbines“), and (8) stationary combustion turbines operated on the North Slope of Alaska (defined as the area north of the Arctic Circle (latitude 66.5° North)).

Similarly, the Reciprocating Internal Combustion Engine MACT has 9 subcategories, as follows: (1) Stationary RICE with a site-rating of 500 brake HP or less, (2) emergency stationary RICE,

(3) limited use stationary RICE, (4) stationary RICE that combust landfill gas or digester gas equivalent to 10 percent or more of the gross heat input on an annual basis, and (5) other stationary RICE. We further divided the last subcategory into four subcategories: (1) 2SLB stationary RICE, (2) 4SLB stationary RICE, (3) 4SRB stationary RICE, and (4) CI stationary RICE.

Recommendation: Use further subcategorization to address special situations, such as limited use boilers and process heaters; turndown, startup and shutdown operations, and boilers and process heaters located at facilities without access to natural gas.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 46

Comment: CIBO Strongly Supports EPA’s Proposal to Create Subcategories of lndustrial Boilers and Process Heaters.
CIBO strongly supports EPA’s proposal to subcategorize industrial boilers and process heaters based on the physical state of the fuel burned. CIBO agrees with EPA’s conclusion that "there are significant design and operational differences between units that burn coal, biomass, liquid, and gaseous fuels" and that "[b]oiler systems are designed for specific fuel types and will encounter problems if a fuel with characteristics other than those originally specified is fired." 75 FR 32017. These subcategories therefore reflect significant technological differences with corresponding differences in the nature, composition, and controllability of HAP emissions, as well as the cost of control. CIBO similarly supports EPA’s ability to subcategorize further among units firing fuel of the same physical state based on size and extent of use. The design and construction of large and small units reflect further technological differences that affect the nature, composition, and controllability of HAP emissions.

Response: See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.
See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA’s authority to create subcategories.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 48

Comment: EPA has Abundant Legal Authority to Create Subcategories as Proposed.

EPA has broad discretion to establish subcategories of sources. Section 112 provides EPA with explicit authority "to establish subcategories under this section, as appropriate." § 112(c)(I); see also § 112(c)(5) (" ...the Administrator may at any time list additional categories and subcategories of sources[.],,). Indeed, § 112 establishes a presumption in favor of the creation and modification of categories and subcategories in the course of the Agency's regulatory program, by mandating that EPA "shall from time to time, but no less often than every 8 years, revise, if appropriate, in response to public comment or new information, a list of all categories and subcategories of major sources." § 112(c)(I). Section 112(c)(I)'s language empowering EPA "to establish subcategories ... as appropriate" without the inclusion of criteria limiting the Agency's ability to do so confers a broad grant of authority.

The D.C. Circuit previously has interpreted the inclusion of the phrase "as appropriate" in a more limiting statutory mandate as conferring substantial discretion. Consumer Federation of America v. U.S. Dept. of Health and Human Services, 83 F.3d 1497 (D.C. Cir. 1996) (Consumer Federation). At issue in Consumer Federation was a provision of the Clinical Laboratory Improvement Amendments of 1988 (CLIA), which directed HHS to establish qualifications for laboratory technicians that "shall, as appropriate, be different on the basis of the type of examinations and processes being performed." Consumer Federation, 83 F.3d at 1503.

The court found that, even though the statutory mandate at issue-using the word "shall"-was phrased in a way generally interpreted to impose a mandatory duty to differentiate qualifications based on different types of tests, the inclusion of the words "as appropriate" removed the mandatory nature of this provision and introduced a significant amount of agency discretion in its implementation. Consumer Federation, 83 F.3d 1497. To hold otherwise, concluded the court, would treat the statutory terms "as appropriate" as mere surplussage, thereby violating a basic canon of statutory construction. Consumer Federation, 83 F.3d 1497. In the CAA context, the mandate conferred by § 112 to establish subcategories "as appropriate" similarly provides substantial discretion for EPA to create subcategories on any reasonable basis. Nothing in the Act or applicable case law suggests otherwise.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 49

Comment: EPA Has Broad Discretion to Distinguish Among Classes, Types and Sizes of Sources, Even Within Subcategories.
While EPA has nearly unfettered discretion to create subcategories as appropriate, the CAA provides ample authority for EPA to distinguish among groups of sources within a source category or subcategory in setting a MACT standard. The statute provides that EPA "may distinguish among classes, types and sizes of sources within a category or subcategory" when

establishing MACT standards. 42 U.S.C. § 7412(d)(I). Congress's use of the broad terms "class," "type," and "size" shows that EPA is intended to have broad discretion in the appropriate factors that warrant distinguishing among sources, and EPA's proposed subcategories fall squarely within the meaning of "types" and "sizes." It is a well-established canon of statutory construction that courts "give the words of a statute their ordinary, contemporary, common meaning, absent an indication Congress intended them to bear some different import." Williams v. Taylor, 529 U.S. 420, 431 (2000) (quotations omitted).

Accordingly, we turn to the standard definitions of "class," "type" and "size." Webster's Third New International Dictionary Unabridged (1993) defines "class" to mean "a group, set or kind marked by common attributes or a common attribute." It defines "type" as "qualities common to a number of individuals that serve to distinguish them as an identifiable class or kind," further clarifying that "[t]ype", "kind" and "sort" are usually "interchangeable and that "kind" in most uses is likely to be very indefinite and involve any criterion of classification whatsoever." To the extent that EPA may distinguish among sources within a category or subcategory on the basis of "any [reasonable] criterion of classification whatsoever," and may create subcategories as appropriate, the CAA strongly supports EPA's authority to create subcategories of industrial boilers as proposed.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Comment: Congress Contemplated and Approved Subcategorization.
The legislative history makes clear that Congress intended EPA to distinguish among classes, types and sizes of sources under three core circumstances: when differences among sources affect (1) the feasibility of air pollution control technology; (2) the effectiveness of air pollution control technology; and (3) the cost of control: The Senate Report clarifies that the Administrator should: take into account factors such as industrial or commercial category, facility size, type of process and other characteristics of sources which are likely to affect the feasibility and effectiveness of air pollution control technology. Cost and feasibility are factors which may be considered by the Administrator when establishing an emission limitation for a category under section 112. The proper definition of categories, in light of available pollution control technologies, will assure maximum protection of public health and the environment while minimizing costs imposed on the regulated community. However, in limited circumstances where a group of sources may share the characteristics of other sources in the category, the Administrator may establish subcategories for such sources. S. Rep. No. 228, 101st Cong., 1st Sess 166.

Thus, in the view of the Senate, the standard for establishing categories and subcategories is essentially the same, although the Administrator is cautioned not to make too rampant use of subcategories. The House Report similarly provides: "EPA may distinguish among classes, types and sizes of sources within a category or subcategory.... In the determination of MACT for new and existing sources, consideration of cost should be based on an evaluation of the cost of various control options. The Committee expects MACT to be meaningful, so that MACT will require substantial reductions in emissions from uncontrolled levels. However, MACT is not intended to require unsafe control measures, or to drive sources to the brink of shutdown." House Rep. No. 101-490, Part 1, at 328. In sum, while Congress intended the MACT program to achieve significant emissions reductions, it also intended EPA to be cognizant of the costs of control, and to ensure that the program did not cause significant economic hardship. One primary mechanism for achieving this goal is through the use of subcategories; subcategorization enables the Agency to account for the fact that distinctions among classes, types and sizes of sources may have a very real impact on the feasibility of a given control technology, the effectiveness of that control technology, and the cost of control.

Comment: Variation of Emission Standards on the Basis of Fuel Type is Valid.
The only case to interpret the "classes, types and sizes" language that supports this interpretation. Sierra Club v. Costle, 657 F.2d 298 (D.C. Cir. 1981) recognized the broad discretion this language confers on EPA to create what in effect are subcategories of sources with differentiated emission standards. This decision interpreted identical statutory language found in the New Source Performance Standards (NSPS) provisions of § 111 of the CAA. Under the "classes, types and sizes" language, the Sierra Club v. Costle court upheld a variable NSPS S02 reduction requirement that was tied to a source's existing S02 emissions levels which, in turn, depended on the sulfur content of the facility's fuel. The Court noted that "[t]he required finding that must underlie a variable standard is much broader than a mere determination that uniformity is not achievable. Rather, EPA has the discretion to vary the standard upon finding that such a departure (from uniform control) does not undermine the basic purposes of the Act." Sierra Club v. Costle, 657 F.2d at 321 (quotations omitted). On this basis, the Court expressly upheld EPA's subcategorization of coal-fired power plants based on the sulfur content of fuel, finding that "[the text of the statute nowhere forbids a distinction based on sulfur." Sierra Club v. Costle, 657 F.2d at 319.

More generally, the Sierra Club v. Costle decision confirms EPA's discretion to set differentiated emissions standards for groups of sources within a category (i.e., for subcategories) even in instances where the strictest standard may be achievable by all sources. The court's analysis in

Sierra Club v. Costle has obvious relevance to an analysis of the authority granted to EPA through CAA § 112. Section 112 employs the same language as § 111 in defining when EPA may promulgate distinct emission standards for sources within a category or subcategory. The Supreme Court consistently has held that "when administrative and judicial interpretations have settled the meaning of an existing statutory provision, repetition of the same language in a new statute indicates, as a general matter, the intent to incorporate its administrative and judicial interpretations as well." Bragdon v. Abbott, 524 U.S. 634, 645 (1998). Therefore, § 112, which adopted § 111's terms almost ten years after the decision in Sierra Club v. Costle, must be understood to carry the settled meaning given to those terms by Sierra Club.

Comment: EPA's Past Practice Regarding Subcategorization is Consistent with the Proposed Subcategories.
EPA's past practice has been consistent with this interpretation of the Act. The Agency has subcategorized sources in numerous industrial categories. From this experience, it is possible to distill several principles that have guided the Agency's decision making with regard to creation of subcategories. First, EPA has determined that subcategorization is appropriate where sources use different processes, and those processes result in different types or concentrations of uncontrolled HAPs. Here, for example, the suite of HAPs emitted by solid-fueled boilers differs from that emitted by liquid-fueled boilers, which in turn differs from that emitted by gas-fueled boilers. For example, the types of metals emitted by solid-fueled boilers differs from the types of metals emitted by liquid-fueled boilers, and gas-fueled boilers typically emit little metals, but may emit more organic HAPs. Thus, subcategorization based on fuel type is appropriate because the different types of boilers emit different types of HAPs. The Agency also has subcategorized sources based on size, where size differences affect the performance of control technologies.

That is also the case here. Thus, subcategorization of boilers based on size, or infrequent utilization, also is consistent with EPA's past precedent and is appropriate because of the impact of these factors on the ability of these sources to maintain the same level of control as larger sources. Furthermore, the Agency has subcategorized sources where differences among sources affect the applicability of control technology. For example, EPA created subcategories in the 1999 polyether polyols production MACT standard, finding "Subcategorization was necessary due to the distinctively different nature of the epoxide and THF processes and its effect on the applicability of controls." Similarly, in the 1998 flexible polyurethane foam production MACT standard, EPA found that "Subcategorization was necessary to reflect major variations in production methods, and/or HAP emissions that affect the applicability of controls." Based on similar rationales, EPA created subcategories in the Group I polymers and resins MACT and the primary aluminum production MACT, and proposed to create subcategories in the polyurethane foam production MACT. Subcategorization based on fuel type is appropriate because the type of fuel affects the applicability of control technology.

EPA also has created subcategories in numerous cases where differences among sources affected the performance of control technology and, hence, the achievability of the MACT standard. For example, in the steel pickling MACT, EPA excluded specialty steel because the technology that is effective for removing acid gas (HCl) emissions from carbon steel manufacturing "may not be as effective" for removing acid gas (H2S04) emissions from specialty steel manufacturing. Similarly, the phosphoric acid manufacturing MACT subcategorized the submerged combustion process and the vacuum evaporation process because the "submerged combustion process is not amenable to the same level of control as is the vacuum evaporation process." In the leather finishing operations MACT, EPA "observed differences in achievable emission levels between the types of leather products produced ... [and therefore] we have established four different performance standards for the various leather products produced." And in the proposed secondary aluminum production MACT, EPA "examined the processes, the process operations, and other factors to determine if separate classes of units, operations, or other criteria have an effect on air emissions from emission sources, or the controllability of those emissions." In sum, EPA’s proposed subcategories are amply supported by the language of the statute, the legislative history, applicable case law and the Agency’s own past practices.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA’s authority to create subcategories.

Comment Excerpt Number: 53

Comment: Need limited use subcategory for liquid or gas 2 units based on 10% annual Capacity factor or 1,000 hours/year as a threshold.
EPA should establish a subcategory for "limited use" units due to their significant differences from steady-state units. Limited use units should have a rated heat input greater than 10 MMBtu/hr with an annual average capacity factor of 10 percent or less. These units operate for short periods of time during the year and as such may experience relatively little SSM. The short run times would likely exacerbate the effect of startup/shutdown on 30 day averages. Because limited use units do not operate regularly, their emissions differ from average boilers operating for longer periods of time or near their design capacity. EPA has recognized that "units operate most efficiently when operated at or near their design capacity." 75 FR 32023-24. Based on their operating schedule, limited use units may or may not operate at or near their design capacity, but if they do it is for limited periods of time. Considering this, limited use units may operate for a

greater percentage of their total operating time inefficiently as compared to steady state units operating near design capacity.

Additionally, the short operating times of limited use units results in difficulties in effectively controlling emissions. As EPA noted in a 2004 response to comments document , based on the operating schedules of limited use units the agency could not identify a control technology for controlling organic HAP emissions. See EPA, Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP, at 67 (Feb. 25, 2004). Considering these differences based on the operating schedule of limited use units, EPA should establish a subcategory for limited use boilers and process heaters. The subcategory should be defined to include units with a capacity utilization factor of 10 percent; or, by a 1,000 hours operating per year threshold.

Furthermore, EPA should adopt a work practices standard for the limited use subcategory. First, EPA's has acknowledged that there is no proven control technology for organic HAP emissions from limited use units. Second, limited use units, such as emergency and backup boilers, cannot be tested effectively due to their limited operating schedules. This is due to the fact that there is often no time to conduct performance tests on a unit operating in a limited capacity and because most EPA test methods require a unit to operate in a steady state. See Proposed 40 CFR 63.7520(d). Based on existing test methods, limited use units would have to operate for the sole purpose of being subjected to emissions testing. Such a result is counter to the general intent behind the CAA. EPA should therefore use its authority under section 112(h) and adopt a work practices standard for limited use units and not subject the subcategory to emissions testing or monitoring.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 54

Comment: EPA Should Create Additional Subcategories.
While CIBO supports EPA's efforts in creating subcategories, EPA has not sufficiently considered the vast array of units and their differences. Units including cyclone-fired boilers do not clearly fit in any of the proposed subcategories. These units vary to such an extent that achieving the emission standard for CO and dioxin/furan in any of the existing subcategories would likely not be feasible. EPA should consider creating a subcategory for units like cyclone-fired boilers that do not fit in other subcategories. Alternatively, EPA should provide clarification as to what subcategory they fall into and the emission standards they are required to meet. Furthermore, CIBO suggests that EPA create subcategories for coal-fired boilers so there is split between units rated at > 1000 MMBtu and units rated at < 1000 MMBtu. EPA should also create a subcategory for fire-tube boilers, including hybrids with water and fire tubes. These

units tend to burn biomass and there combustion is so different they should be classified as small.

Response: See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.
See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size. See response to comment EPA-HQ-OAR-2002-0058-2916.1, excerpt 3 for subcategorizing firetube boilers. EPA determined that insufficient data and techical rationale were provided for a separate cyclone subcategory. According to the survey, 42 boilers checked the "cyclone" combustor design. However, most of these units checked another type of combustor design, so there were only 12 units (10 coal and 2 biomass) that were uniquely classified as cyclone boilers, but are currently classified in the stoker subcategory. These units range between 190 and 640 mmBtu/hr for coal-fired units and 4 to 160 mmBtu/hr for the two biomass units. There are limited data available for cyclone boilers, for example there are only two biomass cyclone boilers with available test data.

Comment: Should the Agency be able to identify specific gases that, because of their composition (e.g., chlorine content), result in significant HAP emissions and, where the emissions from their combustion can be adequately characterized and it is feasible to control them, it could establish emission or fuel standards for those species when they are combusted in a boiler or process heater using the 112(d)(3) process. In that case, the Agency could establish a narrow subcategory as a legal basis for regulating such gases.

The majority opinion in the Brick MACT case does not address the possibility of subcategorization to address differences in the HAP content of raw materials. However, in his concurring opinion Judge Williams stated that EPA‘s ability to create subcategories for sources of different classes, size, or type (CAA section 112 (d)(1)) may provide a means out of the situation where the floor standards are achieved for some sources, but the same floors cannot be achieved for other sources due to differences in local raw materials whose use is essential. (Id. At 88485.9)

Recommendation: Where a HAP in fuel is emitted to the atmosphere through a boiler or process heater and it is feasible to characterize those emissions and where control is possible, the Agency should establish narrow subcategories to address those specific HAPs through 112(d) processes.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type.

Comment: Additional subcategories are needed for new source standards.
The proposed new source standards are unrealistic and, if left unchanged, could seriously endanger the nation's long-term prospects for growth in the manufacturing sector. Reports we hear from suppliers of boilers and air pollution control systems are that they will not be able to supply commercial guarantees to meet the proposed standards. Additional subcategories which focus on the regional fuel supplies (Powder River Basin, Illinois Basin, Central Appalachian, etc) are needed to allow future boilers to be installed across the nation. For example, the top performer used to set the HCl standard for new coal-fired boilers is a boiler which burn sub-bituminous coal, which inherently has much lower chlorine content than eastern coals. A facility on the east coast should not have to meet standards that can be met only by burning a fuel only obtained from hundreds if not thousands of miles away.

Response: See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 61 for additional subcategory based on regional fuel availability or geographic location.

Comment: Include additional fuel oil burning flexibility in the final rule. Work practice standards are more appropriate for fuel oil burning at refinery locations and remote locations without access to natural gas. If EPA decides to proceed to set HAP emission limits on refinery oil units, the ten-percent allowance needs to be made on the collection of heaters and boilers subject to the standards instead of the individual pieces of equipment.

Response: See preamble for discussion of a non-continental unit subcategory.

See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 56

Comment: These comments relate primarily to refineries that combust residual and distillate fuel oil (this term includes distillate range intermediates combusted in some facilities) in process heaters and boilers, but also relate to other oil burning sources such as Alyeska‘s crude oil loading facility. Most oil combustion in the petroleum sector is in locations that are islands or in more remote parts of the United States, since it is those areas where natural gas is not available to balance the fuel supply generated at the location. It is important to note that these facilities burn oil because they must do so, even though it imposes much more complicated operating procedures AND it is significantly more costly than burning natural gas, were it available. This is the case even for combustion of residual fuel oil, which is less costly than ultra low sulfur diesel or No. 2 fuel oil.

Response: See preamble for discussion of a non-continental unit subcategory.

Comment: EPA's approach to subcategorizing the boilers and process heaters in the Gas 1 subcategory for purposes of establishing the potential floors in the preamble fails to account for units designed and operated to minimize emissions of NOx to comply with state and federal permit limits. Units operated to keep NOx levels low will have higher emissions of CO due to the need to minimize excess air to minimize thermal NOx. Thus, CO emissions from these units will be higher than boilers not designed or operated to keep their NOx emissions low and in compliance with permit limits. The CO floor level in the preamble for Gas 1 units ignores these design issues and any emission limits based on the potential CO floor level in the preamble would be difficult, if not near impossible, for these boilers to achieve while also meeting the required NOx permit limits. EPA has discretion to account for design characteristics when setting floors and should do so if work practices are not used.

Response: EPA has adjusted the CO limits, see preamble for a discussion of the revised CO limits. EPA has not promulgated any limits for the gas 1 subcategory.

Comment: Combustion systems for industrial boilers and process heaters are designed first to accomplish a specific duty converting chemical energy to heat to produce steam for process heat and/or electricity generation, pre-heating a hydrocarbon feed for a process reactor, cracking and reforming hydrocarbons, etc. Boilers and process heaters typically have two main sections: a furnace or firebox; and a convective heat exchange section. Combustion of the fuel takes place within the combustion chamber (furnace or firebox). Tubes are carefully placed along the walls or in other arrangements in the furnace to receive large amounts of heat radiating from the flames and surrounding surfaces spread over just the right amount of surface area to accomplish the furnace duty: boil water, crack hydrocarbons, etc. The combustion chambers and burners are designed to fit the flames within the furnace without impinging on the tubes, while maintaining complete combustion, low emissions and oxidizing atmospheres. Roughly 50 to 70 percent of the total heat exchanged in a boiler or process heater occurs in the furnace, depending on the design. Combustion products and gases leave the radiant furnace at temperatures of approximately 1200 to 2000 0F. At these temperatures, radiative heat transfer is lower and convective heat transfer is more efficient. Gases from the furnace then pass through tightly packed tube banks to maintain higher gas velocities for more efficient heat transfer. Gases typically leave the convective heat exchanger at temperatures of approximately 500 to 800 0F.

Industrial boiler designs vary with size, fuel and steam use. Smaller units may be packaged, meaning complete, shop-assembled units that are small enough to transport complete by truck or rail. This can result in longer, narrower combustion chambers to limit the overall width of the unit for transport. Larger units may be field erected, where sections or modules are shipped to the site and final construction and assembly occurs at the facility. The shape, size and temperatures of combustion chambers vary tremendously among designs, depending on duty and fuels (e.g., Figure below). Because of these variations, the combustion environment also varies in terms of temperatures, residence time and mixing. Burners are designed for specific applications to complete combustion and fit the flames within the furnace without impinging on the furnace walls and tubes while delivering heat and producing low emissions efficiently.

[See submittal for image of examples of the variety of different process heater furnace configurations. [Footnote: Baukal, C.E. and Schwartz, R.E. The John Zink Combustion Handbook, CRC Press, Danvers, MA, 2001.]]

Comment: Low-NOx burner (LNB) designs for gas-fired boiler applications manipulate the mixing and stoichiometry within the flame to minimize thermal NOx formation. Staged combustion burner designs establish a fuel-rich zone for the initial phase of combustion, and then add air at a later stage in the outer regions of the flame. In the initial phase of fuel-rich combustion, there is not sufficient oxygen available to form significant amounts of NOx, and in the secondary phase, the flame is much cooler, which also inhibits thermal NOx formation. Ultralow NOx gas burners may also induce recirculation of combustion products into the initial and intermediate combustion stages, decreasing peak flame temperatures and reducing oxygen availability. "Lean premix" burners premix a portion of the fuel and air and initially combust under fuel-lean conditions, adding the balance of fuel and air downstream in a staged manner. This reduces peak flame temperatures in the initial combustion stage that lead to "prompt NOx" formation while also minimizing thermal NOx formation. These improvements in NOx emissions typically are accompanied by narrower limits of fuel-air ratio and turndown for safe operation (to maintain flame ignition stability). However, low-NOx and ultralow-NOx burners often operate with CO emission up to 10 ppmvd in the upper part of the load range. At mid loads, the CO begins to increase near 50 ppmvd, and at low loads, it may exceed 100 ppmvd. These low-NOx burners will not be able to achieve CO emissions as low as 2 ppmvd while maintaining safe operating conditions.

EPA recognizes this effect in its emission calculation guidance. The Agency explains:

"The presence of CO in the exhaust gases of combustion systems results principally from incomplete fuel combustion. Several conditions can lead to incompletecombustion, including insufficient oxygen (O2) availability; poor fuel/air mixing; cold-wall flame quenching; reduced combustion temperature; decreased combustion gas residence time; and load reduction (i. e., reduced combustion intensity). Since various combustion modifications for NOx reduction can produce one or more of the above conditions, the possibility of increased CO emissions is a concern for environmental, energy efficiency, and operational reasons."

AP 42 Section 1.3-4 EMISSION FACTORS 9/98

Comment: 63.7499 lists the subcategories of boilers and process heaters to which the proposed rule applies. We have a general concern with the subcategory list relative to gas and liquid combustion.

On page 30216 of the preamble, EPA explains the data were sufficient for determining that a distinguishable difference in performance exists based on unit design type. Therefore, because different types of units have different emission characteristics which may influence the feasibility or effectiveness of emission control, they should be regulated separately (i.e. subcategorized). Accordingly, we propose to subcategorize boilers and process heaters based on unit design in order to account for these differences in emissions and applicable controls.

While we agree with the Agency‘s conclusion that there are differences in emissions and applicable controls for gas- and liquid-fired boilers and process heaters, we do not believe unit design is the best way to distinguish among these differences. Many boilers and process heaters are designed to burn multiple fuels and many units that were originally designed for one fuel now burn a different fuel. In general, a boiler or process heater designed for a particular gas or liquid can change to another gas or liquid with relatively minor changes, at the most burner and feed system changes. Any boiler or process heater designed to burn Gas 1 (Natural Gas/Refinery Gas) can also burn Gas 2 (Other Gas) or vice-versa and many units originally designed to burn liquids have been modified to burn gas. Thus, the design fuel does not reflect the current fuel situation for gases and liquids. For units designed to burn both liquids and gases, the unit‘s design provides no basis at all for assigning the unit between the gas and liquid subcategories. Thus, many questions arise from using design as the basis for subcategory assignment for these fuels.

We believe the reasonable basis for distinguishing between gas and liquid subcategories is the fuel they actually burn. Except as discussed in the next paragraph, we recommend using the past calendar years as the basis with appropriate consideration of potential changes in subcategory, as discussed in our next comment. Using any type of rolling basis or a time period of less than a year would be a recordkeeping and compliance nightmare with no real regulatory advantage. A calendar year basis is consistent with the basis used for assigning storage vessels and distillation units under Subpart CC.

Recommendation: Base subcategory assignment on the fuels burned in the previous calendar year rather than on the design basis for the unit.

Response: See final rule and preamble for discussion of how units are assigned to subcategories and provisions available to switch subcategories.

Comment: Industrial boilers that have specialized uses and are therefore operated less frequently should be listed in a separate subcategory. Such auxiliary boilers are often operated primarily during plant startups, and as such emit very low levels of HAPs. These boilers should be categorized as those with a 10 percent capacity factor for the maximum hourly heat input, and should be subject to a work practice standard under Section 112(h) of the CAA.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 10

Comment: Small municipal utilities serve a unique and essential role in both the electric industry as a whole and in their communities. As such, these boilers are easily distinguishable from the mass of other boilers and process heaters covered by the Proposed Rule. Both the many benefits provided by small municipal generators and the unique restrictions and challenges they face justify EPA's use of section 112(d)(1)'s subcategorization authority. Local generating facilities are an important component of the mix of electric power suppliers in existence today. They provide numerous, unique benefits to the public including:
Reducing power grid congestion and boosting reactive power;
Increasing the reliability of the electric system;
Increasing the ability of the electric system to meet peak demand;
Providing valuable protection against wholesale electricity price spikes;
Mitigating the impact of regional power failures;
Meeting demand in transmission-constrained "load pocket" areas;
Reducing the vulnerability of the electric grid;
Supplying power to important municipal functions;
Providing high quality jobs to local residents;
Keeping funding in local communities which, in turn, enhances the local economy;
Supplying ideal test sites for the implementation of new energy production technologies;
Increasing energy efficiency through reduction of line losses; and
Enhancing "yardstick competition," thus allowing better assessments of the performance of others in the industry.

These many unique benefits of municipal power generation are sufficient to justify subcategor. However, the unique restrictions and challenges laced by these uenerators further con lirtit the need for a municipal utility subcategory. Such restrictions include:
Legal restrictions prohibiting Ohio municipal generators from selling more than 33% of their kilowatt hours outside municipal limits;
Practical requirements that municipal generators dedicate a portion of their capacity to municipal functions;
The inability of municipal power generators to spread capital and operating costs over broad customer bases;
Constraints on the ability of local communities to finance major capital projects;

Major diseconomies of scale with respect to pollution control equipment on these small electric units, vis-à-vis larger utility units;
Many small municipal electric utility boilers are operated on a "peaking" basis, far less than their operating capacity, forcing these municipalities to spread major capital compliance costs over an even smaller amount of sales; and
Unique political pressures as municipally owned entities.
In addition to the legal constraints that uniquely impact small municipal power generators, the Proposed Rule presents a serious practical problem. Many municipal generation facilities are located in the heart of small towns. Because these towns often literally "grew-up" around these facilities, there is often no way to physically accommodate the substantial expansion needed for new add-on control devices. In many cases, it will be impossible or prohibitively expensive to relocate neighboring facilities. These communities would thus be limited to attempting to retrofit their existing equipment in the limited remaining space. In some cases, retrofitting will be impossible. Where such retrofitting is possible, associated capital costs are likely to increase exponentially. In fact, in nearly all cases the sole viable option will be to shut down.

Their small entity status further distinguishes municipal utilities from the mass of other boiler operators. SBREFA recognizes small governments and small utilities as deserving of special consideration and protection from regulatory impacts. Indeed, in this rulemaking, the SBREFA Panel recommended certain accommodations for small entities - including the establishment of HBELs. Given the financial and legal constraints detailed above, those recommendations should be heeded.

Comment: Many facilities, including Minnesota forest products industries, have backup boilers that operate only when the primary units are down due to malfunction or maintenance. Typically, back-up boilers operate at 10% or less of annual capacity. The cost to upgrade a small package boiler is estimated by AF&PA to be $10 million. It is not cost-effective to add-on expensive pollution control equipment for sources that operate at 10% or less annually. In addition, testing protocols would require operation when the boilers are not needed. EPA should include a subcategory for limited use boilers, or a de minimis applicability threshold for small or limited use units.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: As EPA has recognized, "[black-up or emergency units only operate if another boiler that is the regular source of energy or steam is not operating (for example due to a shutdown for maintenance and repair)." Revised MACT Floor Analysis (Feb. 2004) (EPA-HQ-OAR-20020058-0602). Moreover, these "infrequently operated units typically operate 10 percent of the year or less" [Footnote: This number was calculated using the prior database. For completeness of the administrative record, therefore, we would request that this database be made part of the current docket.], but "[t]hese limited use units, when called upon to operate, must respond without failure and without lengthy periods of startup." 69 Fed. Reg. at 55232. EPA has already recognized that, based on these facts, "their use and operation are different compared to typical industrial, commercial, and institutional boilers" and that "such limited use units should have their own subcategory." Id. Although EPA cannot reverse that decision without a reasoned explanation, the Proposed Rule offers no information on how or why it now omits a limited use subcategory. EPA does not mention either the limited use nature of many boilers or the fact that these boilers must undergo extensive maintenance and readiness

testing despite long periods of disuse in order to "when called upon to operate . . . respond without failure and without lengthy periods of startup. 69 Fed. Reg. at 55232. AMP encourages LP A to remedy this omission by returning the limited use subcategory to the final Boiler MACT rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Failure to create a limited use subcategory is inconsistent with EPA’s decision to rely on similar factors to justify an emergency use subcategory in the recently promulgated MACT for compression-ignition reciprocating internal combustion engines ("CI RICE"). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. 9648 (Mar. 3, 2010). In that rule, EPA recognized that stationary existing CI RICE should be divided into non-emergency and emergency categories "in order to capture the unique differences between these types of engines." Id. at 9650.
Like the limited use boilers described in the 2004 Boiler MACT rule, EPA recognized that emergency CI RICE are required to operate infrequently and for relatively short periods of time,

and so must be kept in working order for prolonged periods when they are not operating. See Subcategorization of Stationary Reciprocating Internal Combustion Engines <500 HP (May 15, 2006) (EPA-HQ-OAR-2005-0030-0012). Some of the specific factors identified by EPA in this memorandum are particularly salient. For example, EPA acknowledged that these CI RICE would need to operate when "electric power from the local utility is interrupted or has become unreliable" which, with the exception of "major catastrophes" would be for short periods of time. Id. at 5. In addition, as "emissions occur only during emergency situations or for a very short time to perform maintenance checks and operator training," EPA found that "[e]missions from these units are expected to be low on an annual basis.” [Footnote: Id. While these criteria focus on an "emergency use" subcategory, it is important to note that the limited duration of the use, not the purpose for using the CI RICE is the key issue. For example, the same rule also creates a subcategory for "black start" engines (engines used to start a turbine generator), which operate during both "emergency and high demand days." 75 Fed. Reg. at 9662.]

These same factors apply to limited use boilers. First, limited use boilers are put into service only during shutdown of the main boiler or "when electric power from the local utility is interrupted or becomes unreliable,"9 neither of which generally requires the limited use boiler to operate more than a short period of time. Second, because of their limited use during the year, "[e]missions from these units are expected to be low on an annual basis." Id. Third, like emergency CI RICE, limited use boilers operate for only a small portion of the year, typically “10 percent of the year of less.”

Without a limited use subcategory, such infrequently operated units would have to comply with emission limits set by units operating on a continuous basis at or near their capacity. That is unreasonable because, as EPA has already acknowledged, "[c]ombustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit’s load (steam production) decreases." 75 Fed. Reg. at 32023. Even if a limited use boiler is called upon to operate at maximum capacity, it can take hours or days to ramp up from a cold start and a similar period of time to cool down. For a unit operating for as little as 15 hours in a month, this could be a substantial portion or even all of the time during which the boiler is operating. As a result, limited use boilers will seldom be operating at maximum capacity or maximum efficiency. Without a limited use subcategory, the regulations will be comparing these boilers to ones EPA has already recognized are operating under more efficient circumstances. This is both unreasonable and arbitrary.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: The problem is further amplified by EPA’s current decision to include periods of startup and shutdown in the MACT floor analysis. [Footnote: Continuous emission monitoring data is not available for all pollutants in the database. To the extent that emission limits are based on stack test data that does not consider SSM events, EPA is obliged to use other available

"emission information" which may include calculations based on an operator's knowledge and engineering analysis. This emission information should be used to properly incorporate SSM variability into the MACT floor analysis.] EPA found in the Proposed Rule that including these periods will be justified because "the standards that we are proposing are daily or monthly averages" and because "[b]oilers, especially solid fuel-fired boilers, do not normally startup and shutdown more [than] once per day." [Footnote: Even this appears to be a vast overstatement. Taking all boilers and process heaters reporting startups per year in
EPA's Materials Combusted Table, the average is only 44.7 per year, including small units and process heaters] Id. at 32013. Moreover, EPA found that "[p]eriods of startup, normal operations, and shutdown are all predictable and routine aspects of a source's operation." Id. These findings do not apply to limited use boilers. First, these boilers will seldom be called upon to operate during an entire 30-day period and so cannot practically average emissions over a month, even assuming that testing equipment and personnel are ready immediately upon startup. Even a daily average is insufficient for the 15-hour months that were characteristic of the Painesville limited use boiler. Second, since limited use boilers are only operated in emergencies or when another boiler is down, their use is neither predictable nor routine.
EPA should not require limited use boilers to comply with standards set by the best operated 12% of a group of more efficient units operating with the benefit of a 30-day averaging period during periods of planned usage. To do so would create a technically infeasible limit.

Document Control Number: EPA-HQ-OAR-2002-0058-2755.1
Comment Excerpt Number: 15

Comment: EPA should promulgate work practice standards for utility auxiliary boilers.

Electric utilities operate auxiliary boilers that will be subject to the IB MACT because they are not steam generating units that produce electricity. Auxiliary boilers operate infrequently – normally only during plant startups – and combust either natural gas or distillate fuel. As a result, HAP emissions from auxiliary boilers are exceedingly low and therefore do not pose any risk to public health.

Under the proposed IB MACT, gas-fired auxiliary boilers are subject to work practice standards requiring an annual tune up. By contrast, the proposed IB MACT requires oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not lead to any significant environmental benefits.

EPA should create a limited use subcategory for auxiliary boilers combusting distillate fuel that would subject those units to the same work practice standards as gas-fired units. The limited use subcategory should have a 10% capacity factor threshold. Eligibility for this subcategory would be determined based on 10% of the maximum hourly heat input of the boiler multiplied by 8760 hours per year.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 25

Comment: If considering variability in fuel quality across di Iferent types of fuel within a single subcategory is too difficult, that may be an indication that EPA should subcategorize based on fuel types down to specific fuels and materials. Additional subcategorizing within fuel groups appears particularly warranted here, given that EPA has (rightfully) ruled out fuel switching as impossible for many regulated sources.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type.

Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 57

Comment: For units with limited service such as electric utility auxiliary boilers, EPA's proposed work practice standards for units that burn natural gas may be more than is needed, but it is neither cost prohibitive nor technical infeasible. On the other hand, the proposed compliance provisions appear unreasonable for limited use boilers that burn distillate oil.19 First, the cost for sources with oil-fired auxiliary boilers to install and maintain the control equipment (and potentially monitoring equipment) necessary to meet the proposed emissions standards would be excessive, particularly for a unit that may operate with an annual capacity factor less than 10%. In fact, many electric utilities will likely retire such boilers and lease temporary boilers for unit start-up, which are exempt under the proposed rule, rather than invest in the controls necessary to meet the proposed limits. This provides no environmental gain since emissions from the temporary boilers would be the same if not worse than the existing boilers. Second, because the demand for an auxiliary boiler to operate is almost impossible to forecast, it is almost a certainty that each auxiliary boiler would have to be operated some time during each year for the sole purpose of emission testing. Such an outcome would result in a number of unintended, negative consequences: (1) unnecessary air pollutants would be generated; (2) unnecessary carbon emissions would occur; and (3) a valuable and not unlimited resource (low sulfur diesel fuel) would be wasted.

RMB recommends that EPA create a separate subcategory for limited use, oil-fired boilers and suggests that the work practice standard currently applied to gas-fired boilers (boiler tune-up) be applied in lieu of emissions standards. We believe that the application of a work practice standard is justified in this case due to the cost impact.

RMB notes that the vacated IB-MACT rule contained several limited-use subcategories, including new/reconstructed limited use solid fuels, new/reconstructed limited use liquid fuels, and new/reconstructed limited use gaseous fuels, and existing limited use solid fuel. [Footnote: Limited use subcategories were not necessary for existing gas and liquid fire units because EPA had determined that the MACT floor for these units was "no emissions reductions."] The limited use subcategory in the vacated rule applied to sources with an annual capacity factor of 10% or less, such as auxiliary boilers at electric power plants. While EPA embraced the use of limited-use subcategories in the vacated rule, they have not provided any justification for eliminating these subcategories in the proposed rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Document Control Number: EPA-HQ-OAR-2002-0058-2963.1
Comment Excerpt Number: 1

Comment: TVA, as well as most other utilities, operates auxiliary boilers that will be subject to the proposed IB MACT rule because they do not generate steam for producing electricity. In TVA's case these auxiliary boilers are used for startups to provide steam for steam-driven equipment such as fans and pumps until the main boiler comes on line. In other instances auxiliary boilers may be utilized to provide freeze protection when all electric generating units at a site are down. Many of these boilers operate infrequently with some not being used for years. All of TVA's auxiliary boilers are fired by natural gas or No. 2 fuel oil. Two have heat input capacities >250 MMBtu/hr, two are >100 MMBtu, seven are >10 MMBtu/hr and three are <10 MMBtu/hr.

In the proposed rule units burning natural gas are only required to perform a tune-up and the distillate fuel oil units are subject to emissions testing, monitor installations, emissions averaging and reporting. These additional requirements for distillate fuel units are unnecessary and produce little, if any, environmental benefit for limited use boilers.

It is recommended that EPA establish a limited use subcategory for distillate fuel boilers that are operated only occasionally and regulate these units under the same work practice standards proposed for gas-fired units. Distillate fuel units meeting this limited use definition should have a 10% capacity factor threshold, based on 10% of the maximum hourly heat input of the boiler on an annual (8760 hours) basis.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 1

Comment: Subcategory for Municipally- Owned Electric Units: EPA should create an additional subcategory of covered units for municipally-owned electric units, because of the unique technical and institutional issues associated with these units. Only electric utilities have an obligation to serve under law, unlike other industry sectors. Public power systems are distinct from investor-owned utility systems because public power systems are (with a very few exceptions) small, non-profit, local government entities that are covered by the protections of the Small Business Regulatory Enforcement Fairness Act, including the recommendations of the Small Business Advocacy Panel convened for this EPA rulemaking. Further, because public power systems tend to rely heavily or exclusively on one generating plant for most or all of its electric generation and service, those public power units are essential for electric reliability in their jurisdictions. Moreover, public power entities provide electricity on a cost-of-service basis without any profit markup. which means that the costs of difficult MACT compliance will be borne directly by the customers of these struggling Michigan economies.

The different structures, characteristics and functions of public power systems and their small electricity generating units make these units distinct from non-public power systems, and this justifies the creation of an additional MACT sub-category for municipally-owned and — operated electricity generating units that, without a subcategory, will suffer disproportionate impacts from this rule. For this municipal utility sub-category, EPA should develop reasonable emissions limitations and standards based on the best-performing sources within that subcategory — particularly monitoring flexibility and health-based limitations for acid gases as recommended by the Small Business Advocacy Panel.

Response: The EPA sees no technical or legal justification for creating a separate subcategory for small municipal utilities or subcategorizing according to sector. Boilers at municipal utilities fire the same type of fuels, have the same type of combustor designs, and can use the same type of controls as other units in the large subcategory. We would also like to clarify that subcategories were developed based on combustor design and not on industrial sector. Also, had we gone beyond-the-floor, we would have considered cost in the final determination. Since we did not go beyond-the-floor level of control, cost did not play a role in the analysis. See response to comments Document Control Number: EPA-HQ-OAR-2002-0058-2601 Comment Excerpt Number: 3 for assessment of economic impact.
EPA thanks the commenters for providing their statements of potential effects of the rule to small communities. EPA has incorporated several monitoring flexibilities and work practices into the rule to help reduce the burden on certain small entities.

Commenter Affiliation: U.S. Small Business Administration
Document Control Number: EPA-HQ-OAR-2002-0058-2916
Comment Excerpt Number: 2

Comment: EPA Should Have Adopted Additional Subcategories

SERs recommended that EPA adopt the following subcategories for boilers:

Fuel type (including coal rank, bagasse, biomass by type, and oil by type);
Boiler design type (e.g. fluidized bed, stoker, fuel cell, suspension burner);
Duty cycle;
Geographic location;
Boiler size;
Burner type (with and without low-NOx burners);
Process heaters;
Limited use boilers.

Subcategorization as outlined above was a primary flexibility concern of the SERs during the SBREFA panel. The panel report states that, "SERs commented that subcategorization is a key concept that could ensure that like boilers are compared with similar boilers so that MACT floors are more reasonable and could be achieved by all units within a subcategory using appropriate emission reduction strategies." [Footnote: SBAR Panel Report at 22.] While the Panel did recognize that the entire list of potential subcategorizations asked for by SERs was not practicable because of overlap in the categories, EPA should have proposed some additional subcategories as recommended by the panel. EPA has almost complete discretion to establish any subcategories "as appropriate." [Footnote: Section 112(c)(1) of the Clean Air Act. EPA may distinguish among classes, types and sizes of sources within a category. House Report No. 101-

490, Part 1 at 328.] Without the additional subcategories, it increase the cost and difficulty for many small sources to meet emissions standards when they are placed in a category that is driven by the efficiency of very different boiler units running on different fuels, under different duty cycles, and most likely designed for very different purposes. In many cases, forcing boilers into categories where they do not belong will require costly investments to meet standards that are simply not achievable for certain boiler and fuel types, while yielding small or insignificant environmental benefits. In particular, it is very hard to justify why limited use boilers should be subject to the same standards as other boilers. [Footnote: This contrasts strongly with the treatment of the recent MACT standards adopted for limited use reciprocating diesel and spark ignition engines, promulgated by the Agency in 2010, creating a separate category for limited use engines and emergency use engines (e.g engines that run less than 24 hours per year). EPA does not explain the disparate treatment.] EPA did include a "limited use" subcategory for boilers with average capacity factors of 10% or less in the 2004 boiler rule.

Response: See response to comments EPA-HQ-OAR-2002-0058-2916, excerpt 2 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 54 for subcategories based on design type, and for cyclone, firetube, and hybrid watertube-firetube boilers.
See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.
Please refer to the preamble for discussion of the limited use subcategory.
See response to comment EPA-HQ-OAR-2002-0058-1841.1, excerpt 2 for bagasse boiler subcategory.
See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 148 for further subcategorization by fuel type.
See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 61 for additional subcategory based on regional fuel availability or geographic location.
See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.
See response to comment EPA-HQ-OAR-2002-0058-2912, excerpt 2 for separate subcategories for process heaters and boilers.

Commenter Name: David Z. Skolasinski
Commenter Affiliation: Cliffs Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-2881.1
Comment Excerpt Number: 2

Comment: Establishing Emission Limits For Large Heating Boilers Is Unnecessary And The Requirement For Demonstrating Compliance With Emission Limits Is Impractical
Cliffs operates a number of both large and small oil-fired heating boilers at its mining facilities. The boilers provide heat to mine facility buildings including offices, ore processing facilities, maintenance shops, warehouses, and other similar types of buildings. The boilers typically operate during October through May of each year. During this period, the boilers provide heat to

the buildings on an as needed basis. Cliffs requests that EPA reconsider the establishment of emission limits and associated stack testing for seasonally operated, large (10 MMBtu/hr or greater) oil-fired and possibly also solid fuel fired heating boilers and instead require only annual tune-ups similar to those for large gas-fired boilers. The rationale for this request and recommendation is set forth below.

Depending on the boiler design and type of oil burned, the boilers operate in one of two ways. In one case the boilers operate similar to a furnace in a residential home. When the building temperature drops to a predetermined level the boiler turns on and operates until the desired temperature in the building is achieved and then the boiler shuts off. During the fall, spring, and occasional warm winter periods, the boilers typically operate on a cycle of 15 minutes on followed by 45 minutes off. During the colder winter months the boilers typically operate on a cycle of 15 minutes on followed by 20 minutes off.
Boilers that burn heavier liquid fuel such as No. 6 oil remain on continuously but operate at some percent of capacity depending on the level .of heat called for in the buildings. During the fall and spring months the boilers may operate at only 25% capacity while during the winter months they may operate at 75% - 100% of capacity. However, the daily operating rate of the boiler is adjusted manually depending on the weather and the heat requirements in the building, and the operating rate typically also varies between day and night. There are also times especially in the fall and spring when occasional warm days occur that the boiler operations are reduced to essentially an idle. In all cases, any heat produced must be delivered to the building heating system.

Response: The EPA sees no technical or legal justification for creating a separate subcategory for seasonal units. However, a limited use subcategory has been created for units operating less than 876 hours per year. It was developed to represent a specific type of boiler, those used as backup, emergency, or peaking units that operate infrequently. The subcategories at proposal and in the final rule are based on differences in fuel states, combustor types, and use of boilers and process heaters. If a seasonally operated boiler meets the definition of a limited use unit, it would fall under this subcategory. The EPA, however, sees no justification for changing the limited use capacity factor. A review of the information gathered on boilers also shows that a number of units operate as backup, emergency, or peaking units that operate infrequently. The boiler database indicates that these infrequently operated units typically operate 10 percent of the year or less. These limited use boilers, when called upon to operate, must respond without failure and without lengthy periods of startup. Since their use and operation are different compared to typical industrial, commercial, and institutional boilers, we decided that such limited use units should have their own subcategory.

Commenter Name: Ann W. McIver
Commenter Affiliation: Citizens Energy Group
Document Control Number: EPA-HQ-OAR-2002-0058-2875.1
Comment Excerpt Number: 2

Comment: Citizens believes that the use of subcategories is appropriate and supports EPA’s decision to identify subcategories in the proposed rule. Combustion design and type of combustor, as well as fuel, influence the emissions produced during combustion. However, Citizens requests that EPA add a subcategory for limited use boilers and process heaters to the previously identified subcategories.
In the 2004 final rule, EPA promulgated a limited use subcategory. This subcategory was defined generally as units with annual average capacity factors less than ten percent (10%). Within the universe of potentially affected units, many are operated as stand-by or redundant capacity. Such units are reserved for use during periods when circumstances mandate the need to provide steam in order to preserve conditions within the distribution system. These boilers are often equipped with coils to maintain internal metal temperatures, as well as boiler drum pressure and temperature, to allow for quick response following the combustion safety purge.

Citizens believes that the justification for the limited use subcategory continues to exist, and that the promulgation of a limited use subcategory will not compromise the environmental benefits associated with this rulemaking.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 2

Comment: Subcategorize Boilers and Process Heaters. Boilers typically are designed differently than process heaters, operate differently, have historically been regulated differently and typically have higher heat duties. Additionally, boilers all operate in a narrow range of firebox temperatures, while process heaters operate over a very wide range, resulting in a much broader range of emissions from process heaters than from boilers.

Typically process heaters are smaller than boilers, since process heater duty is matched to the process need, while boiler duty is matched to site steam demands. Because heat distribution is critical in process heaters, they typically have many smaller burners and those burners can be located in the floor, the walls or even in the roof. Because they have many burners and lower total firing, oxygen control is typically not as sophisticated on a process heater as on a boiler. Process heaters can and do vary substantially in operating rate, but over longer time spans than boilers, because process heat demands do not vary as quickly as steam demands.

Process heaters are designed for the process that they support. One key variable is firebox (bridgewall) temperature, which can vary in different processes by 600 or more degrees because of the heat needed for a particular type of process. Design differences in process heaters to support the functions of different units lead to differences in residence time and temperature, both of which have a significant impact on emissions.

It is clear from simple inspection that combustion conditions in boiler and process heaters are not the same and that there emissions and control approaches are not be the same. It is obvious that there should be separate subcategories for each of these combustion unit types for each fuel category.

Response: The EPA does not see justification for creating a separate subcategory for both process heaters and boilers. Most process heaters are firing refinery gas, which is covered under the work practice standard. Therefore there is not a utility in separating this subcategory as neither subcategory is subject to emission limits and insufficient remaining data to establish separate MACT floors for boilers vs. process heaters.

Comment: Section 112(d)(1) of the CAA allows the Administrator to distinguish among "classes, types, and sizes of sources" in establishing MACT standards. In providing EPA discretion to create subcategories, § 112(d)(1) does not restrict subcategorization to cases where the "class", "type" or "size" factors affected HAP emissions. The provision merely requires EPA to establish regulations for each category or subcategory on the schedules set out in § 112. Tampa Electric appreciates EPA's effort to create several subcategories in the proposed IB MACT rule. However, EPA should have created additional subcategories. A limited use subcategory should be created for IBs that are operated infrequently or at low capacity because of their specialized nature and use.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Units greater than 100 MMbtu/hr must install a CO monitor and demonstrate compliance on a 30-day rolling average. As explained above TVA has two limited use boilers >100 MMBtu/hr that are run infrequently. These boilers typically run only for short durations in transient mode when CO emissions would be expected to be at the higher end of a unit's emission range between startup and shutdown. Without the limited use subcategory recommended above these units would likely have to be run many additional days just to get the rolling average to be below the limit. Also without the limited use subcategory these two units would be required to have CO and oxygen monitors and would need to be run unnecessarily just to perform required emissions testing, monitor maintenance and QA checks.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Our 1996 oil-fired boiler is an auxiliary or intermittent back-up boiler used to supplement steam supply during maintenance downs or other situations when the mill needs a little extra steam. These rules would require the installation of the same amount of multiple

pollution-control devices as our main hog fuel boiler to meet the proposed limits. Even if we can find a supplier to provide the pollution-control equipment, this cost is prohibitive. Shutting down our newest boiler will result in reduced stability of steam delivered throughout the mill, increased strain on the other steam units, constrained planned maintenance on other parts of the mill, and curtailed production.
Our oil-fired boiler is fueled by Reprocessed Fuel Oil (RFO) which is an on-spec product that was developed with Washington State to reduce the amount of petroleum-based products disposed of in landfills and storm drains.

Much like the Gas 1 category, EPA has ample justification to create a subcategory for intermittent boilers andjor boilers that run on clean liquid fuels that could be subject to work practices and other alternative approaches rather than stringent HAP limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 3

Comment: We believe that it is important for the proposed rule to set standards consistent with the Clean Air Act determination methodology. Because of the large number and variability of affected sources, more source categories than currently proposed by EPA would improve the rule and allow EPA to more successfully apply the methodology and address the differences between source types, sizes, and fuels.

Response: The EPA has created additional subcategories for limited-use units, combined grate/suspension firing units, and non-continental units. Please refer to the preamble for discussion of these new subcategories.
Section 112(d)(1) of the CAA states “the Administrator may distinguish among classes, types, and sizes of sources within a category or subcategory” in establishing emission standards. Thus, we have discretion in determining appropriate subcategories based on classes, types, and sizes of sources. We used this discretion in developing subcategories for the industrial, commercial, and institutional boilers and process heaters source category.
Through subcategorization, we are able to define subsets of similar emission sources within a source category if differences in design, processes, APCD viability, or opportunities for pollution prevention exist within the source category. We first subcategorized boilers and process heaters based on the physical state of the fuel (solid, liquid, or gaseous), which will affect the type of pollutants emitted and controls applicable, and the design and operation of the boiler, which influences the formation of fuel-based HAP emissions. We then further subcategorized boilers and process heaters based combustor design, which will affect the operation of the unit which in turn influences the formation of organic HAP emissions.

Our distinctions are based on technological differences in the equipment. The EPA contends that neither the subcategories nor MACT floor analysis was conducted considering costs, either in the proposed rule or in the final rule.

Comment: Xcel Energy supports the inclusion of a de minimis category based on hours of operation. Many boilers in this category, especially liquid-fueled boilers, are only operated for a limited number of hours each year. For such limited-use boilers, conducting annual stack tests could represent a significant portion of the unit's total operating time. It makes no sense to require extensive testing and monitoring for units that are rarely used. We suggest that units that operate for less than 500 hours per year be exempt from the monitoring and testing requirements.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Document Control Number: EPA-HQ-OAR-2002-0058-3171
Comment Excerpt Number: 3

Comment: An additional subcategory that EPA needs to establish is one for "limited use" units. Because limited use boilers do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers can vary significantly from those of a similar boiler operating in a steady state. A capacity utilization factor of 10% was chosen for the previous boiler MACT final rule as the best means of defining a limited use unit. This definition is equally appropriate for the current rule. Also, given the limited and sporadic operation of emergency and auxiliary boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should require work practices in lieu of emission limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: 1. Clean Air Act
The overall approach taken by EPA appears to be that the only real design differences that merit subcategorization deal with fuel type. In other words, EPA seems to view process heaters and boilers throughout a wide range of industries as basically the same thing and the design differences between them as being insignificant and as not giving rise to differences in emissions of HAPS, taking comfort from what appears to be a broad array of data. This broad brush approach appears to be inconsistent with Section 112(c)(1) of the Clean Air Act

Section 7411 of the Clean Air Act establishes the New Source Performance Standards program. As regards boilers, Section D and subsequent amendments distinguish both on size, heat release, type of liquid fuel used and design. Importantly, for reasons that will be discussed below, NSPS Db includes separate standards for "non-continental" units. Many of these distinctions do not appear anywhere in the Boiler MACT rule. As to process heaters, they have typically been regulated on an industry by industry basis. For example, NSPS Ja regulates fuel gas combustion devices at refineries, including co-fired units.
[Footnote 4: NSPS KKKK also includes a non-continental standard]

Response: See preamble for discussion of a non-continental unit subcategory.

Comment: This same 2007 vendor proposal had a performance guarantee of 0.03 lb/MMBtu for PM when firing No. 2 fuel oil, a magnitude higher than the 0.004 lb/MMBtu being proposed. Without the limited use subcategory, meeting this proposed standard would likely require the installation of additional controls on units run very infrequently. The actual emissions reduction achieved with any such additional controls would be minimal and the cost would be substantial.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Caroline Choi
Commenter Affiliation: Progress Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2868.1
Comment Excerpt Number: 4

Comment: Section 112(d)(1) of the CAA allows the Administrator to distinguish among "classes, types, and sizes of sources" in establishing MACT standards. In providing EPA discretion to create subcategories, § 112(d)(1) does not restrict subcategorization to cases where the "class", "type" or "size" factors affected HAP emissions. The provision merely requires EPA to establish regulations for each category or subcategory on the schedules set out in § 112. Progress Energy appreciates EPA's effort to create several subcategories in the proposed 1B MACT rule and requests that EPA create additional subcategories. A limited use subcategory should be created for industrial boilers that are operated infrequently or at low capacity because of their specialized nature and use.

For example, electric utilities operate auxiliary boilers that will be subject to the IB MACT rule because they are not steam generating units that produce electricity. Auxiliary boilers operate infrequently or in a warm standby mode and combust either natural gas or distillate fuel. As a result, the HAP emissions from the auxiliary boilers are very low and do not pose a risk to public health.
Under the proposed rule, gas-fired auxiliary boilers are subject to work practice standards requiring an annual tune up. By contrast, the proposed IB MACT rule requires oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not produce significant health or environmental benefits.

Progress Energy urges EPA to create a limited use subcategory for boilers combusting distillate fuel that would subject those units to the same work practice standards as gas-fired units. The limited use subcategory could have a 10% capacity factor threshold based on 10% of the maximum hourly heat input of the boiler multiplied by 8760 hours per year. Alternatively, distillate oil-fired boilers that operate in a warm standby mode at less that 10 mmBtu/hour a majority of the time could also be subject only to work practice standards.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 4

Comment: Moreover, the data presented by EPA is insufficient to reach any conclusion about differences between types of units or even as to fuel types and EPA appears to have skipped over the technical step of trying to assess legitimate design differences between units in favor of data crunching and ICR requests to find units with design characteristics that result in lower emissions, rather than looking for legitimate unit design differences and then crafting a testing program. We disagree with the "one size fits all" view and believe that significant differences do exist in the design of process heaters and boilers and that EPA policy and the Clean Air Act support subcategorization.

Heaters and boilers should be subcategorized by industry, location and even by unit type or size, because design and operating differences are relevant to emissions of HAPS from those units and such categorization and subcategorization is consistent with Section 111 and 112(c)(1) of the Clean Air Act.

Response: See response to comments EPA-HQ-OAR-2002-0058-2916, excerpt 2 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 54 for subcategories based on design type, and for cyclone, firetube, and hybrid watertube-firetube boilers.

See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 61 for additional subcategory based on regional fuel availability or geographic location.

See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.

See response to comment EPA-HQ-OAR-2002-0058-2795.1, excerpt 1 for additional subcategory for small municipal utilities or subcategorizing according to sector.

Comment Excerpt Number: 4

Comment: EPA's September 13, 2004 rule included a "limited-use" subcategory for units with average capacity factors of 10% or less, however the proposed rule does not continue that approach. Instead, it presumes that limited use units are just like those operated full-time which burn a similar fuel.
Limited use sources operate intermittently and for shorter periods of time (e.g., small package boilers that are only used during mill outages, a backup boiler that runs when other units are being fixed, or a peaking unit used to supplement electric generation during particularly hot summer days). Compared to most boilers, these units spend a far greater percentage of their time starting up and shutting down. As a result, their emissions profiles differ from sources which operate in efficient steady-state manners. For example, they are likely to experience higher CO levels as the boiler heats up due to incomplete combustion. Similarly, many pollution control technologies are either difficult to use or ineffective during startup and shutdown periods and would be cost prohibitive to install and use for only short periods of time during a year. These are just the sort of "class" and "type" distinctions which merit consideration for subcategorization under §112(d)(2).

A capacity utilization factor of 10% was chosen for the previous boiler MACT final rule as the best means of defining a limited use unit (69 FR at 55223). This definition is equally appropriate for the current rule. Given the limited and sporadic operation of emergency and backup boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should require work practices in lieu of emission limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 4

Comment: EPA should add a subcategory for ICI Boilers with capacity factors less than 10 percent.
FGCO has a number of liquid fired (No. 2 fuel oil) ICI boilers with rated heat inputs greater than 10 mmBtu/hr subjecting them to the proposed ICI Boiler MACT limits. These industrial-sized boilers are used very infrequently to provide a source of steam to power steam driven auxiliaries for much larger electric generating units (EGU) during the start-up process. When the EGU achieves steady-state operation (which is typically a matter of hours), the steam supply is switched over from the auxiliary boiler to the EGU, and the auxiliary boiler is shut down.

None of these auxiliary boilers has operated more than 10 percent of the time on an annual basis and in most cases they operate much less than 5 percent. Some units are even limited by Title V requirements to less than 5 percent annual operation. To impose these ICI Boiler emission limits on limited use boilers is unnecessary, exceedingly costly, provides very nominal environmental benefit at best, and may even result in less efficient power plant operation and more emissions for the following reasons.

First, these auxiliary boilers are generally used to power steam-driven auxiliary equipment for overall system efficiency purposes. (It is more efficient to use steam-driven auxiliaries than electric motors because you eliminate the efficiency losses associated with converting the energy in the steam to electricity and then powering an electric motor to drive the pump or fan.) This improves the overall efficiency of the EGU and results in less overall emissions per unit of output. The imposition of extremely stringent ICI Boiler emission limits on these limited use auxiliary ICI boilers may force the power plant to retire the auxiliary boiler and convert the steam driven auxiliary equipment to electric motors. Likewise, where these auxiliary boilers are utilized to augment plant heating when the larger EGU is shut down, the facility may elect to install less efficient electric heating, since the power supply is readily available. In effect, EPA may force the shutdown auxiliary boilers and reduce the efficiency of power plant operation.

Second, operation of these limited use auxiliary boilers at a power plant occurs at largely random intervals associated most frequently with unplanned outages and startups of larger EGUs. As such, it may be impossible to predict when the auxiliary boiler will be in operation and the unit may have to be artificially scheduled to operate to conduct periodic compliance demonstrations or calibrate monitoring equipment. Starting up one of these auxiliary boilers, consuming fuel and producing emissions just to demonstrate compliance will likely also increase overall emissions from the facility and is counterproductive and a poor use of resources.

Third, starting the auxiliary boiler to demonstrate compliance when the larger EGU is operating leaves the auxiliary boiler with no place to send its steam for meaningful use and benefit. In most instances, the auxiliary boiler will be forced to vent its steam to the atmosphere for the duration of the compliance demonstration or calibration. This would be an absolute waste of fuel and the auxiliary boiler would be creating emissions for the sole purpose of demonstrating compliance. In certain instances, the auxiliary boiler may not even have a means to vent the steam to the atmosphere since this mode of operation is so counterintuitive and may have never been contemplated.

These counterintuitive, unintended consequences argue against applying stringent ICI Boiler MACT limits on infrequently used auxiliary boilers at an EGU. Accordingly, EPA should add a subcategory for ICI Boilers located at EGUs with capacity factors less than 10 percent to avoid increased emissions and reduced efficiency from both the EGU and their auxiliary boilers.

Comment: Work Practice Standards Should Apply to Limited Use and Small Boilers. MP commends EPA's decision to apply work practice standards to gas-fired boilers. These work practice standards should be expanded to oil-fired limited-use and small boilers, such as utility auxiliary boilers. HAP emissions from limited-use and small boilers firing distillate fuel are exceedingly low and do not pose a risk to public health. Applying stringent emission limits to these boilers could result in expensive compliance costs with no meaningful environmental benefits. Since these emissions would be low, EPA should create a separate subcategory for these limited-use boilers, and apply the same work practice standards currently proposed for gas-fired boilers.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: The NESHAP should appropriately class and assess types of boilers and the fuels they use when setting standards and emission limits.

The proposed rule should acknowledge the diversity and variability of top performing boilers across sectors of the economy, including differences in function, load, fuel mix and pollution control efficiencies when setting emission standards.

EPA should consider segregating boilers by size. Segregating boilers by size consistent with the size ranges in the NSPS rules for boilers (Subparts D, Db, and Dc) may be a reasonable approach.

Response: See response to comment EPA-HQ-OAR-2002-0058-2798.1, excerpt 9 for subcategorizing according to NSPS rule's heat input size structure.

Commenter Name: Kathryn M. Cunningham
Commenter Affiliation: Consumers Energy Company
Document Control Number: EPA-HQ-OAR-2002-0058-2904.1
Comment Excerpt Number: 5

Comment: Consumers operates a number of its boilers/heaters on a limited basis due to cold weather conditions. For example, one of the distillate oil fired boilers that contributed to the ICR Part II, operates at a capacity of less than 10%. When it does operate, it is at variable load ranges, depending on ambient temperature. It is used to heat a molten sulfur storage tank and also for building heat. The ICR testing was not done at variable load ranges and thus did not capture actual emissions that the boiler may typically emit. Due to the limited use of this boiler, it is impossible to meet the emission limits as proposed - even on a 30 day rolling average,. Consumers is advocating for an exemption from the emission limits for boilers with limited use — less than 10% capacity. Consumers believes the work practice standard should apply to these boilers instead of the emission limits.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Section 112(d)(1) of the CAA allows the Administrator to distinguish among "classes, types, and sizes of sources" in establishing MACT standards. This subcategorization language mirrors earlier language found in CAA § 111. In providing EPA discretion to create subcategories, § 112(d)(1) does not restrict subcategorization to cases where the "class," "type" or "size" factors affect HAP emissions. The provision merely requires EPA to establish regulations for each category or subcategory on the schedules set out in § 112. Indeed, EPA has not previously subcategorized under § 111 based solely on emission effects. For example, under § 111 EPA has subcategorized boilers on the basis of size (heat input) or the type of fuel burned (coal, oil or gas). These subcategorization decisions were based on feasibility and/or cost considerations, not on the level of emissions.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

See response to comment EPA-HQ-OAR-2002-0058-2987.1, excerpt 3 for basis of subcategorization.

Commenter Name: Sheila C. Holman
Commenter Affiliation: North Carolina Department of Environment and Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-2798.1
Comment Excerpt Number: 9

Comment: In the proposed rule, the only sub-categorization based on heat input size is a 10 MM Btu/hr threshold. The proposed MACT for existing sources greater than 10 MM Btu/hr includes add-on control devices such as scrubbers, ESPs, sorbent injections systems, etc., which have significant capital and operating costs. The cost and cost-effectiveness (dollars per emission amount reduced) is highly dependent on heat input size, and larger combustion sources are more highly controlled than smaller sources. This fact is manifested by EPA's New Source Performance Standards Subpart Dc for Industrial Boilers. While it may be technically-feasible to install a wet scrubber on a 250 MM Btu/hr coal fired-boiler, the cost of such control on a 15 MM Btu/hr boiler is not economically feasible for most facilities. To avoid forcing small units to retrofit add-on controls that have not been demonstrated to be cost effective, NC DAQ recommends using a similar heat input size structure with progressively more stringent standards as in 40 CFR. 60, Subpart Dc: (1) less than 30, (2) 30100, (3) greater than 100, (with all categories in units of MM Btu/hr, but raising the threshold from 10 to 30 MM Btu/hr as suggested above).

EPA should further subcategorize the MACT standards based on heat input size for solid fuel fired boilers and heaters. In order to evaluate and help justify further sub-categorization, EPA should:

Size-segregate the source populations,

Rank HAP emissions by sources for each size category

Identify the emission control technologies in each category,

Characterize the extent of existing emission controls in each category,

Estimate the cost-effectiveness of adding emission controls for each category.

Rank each category's control cost-effectiveness for each HAP.

Response: See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.

Commenter Name: Christopher S. Colman
Commenter Affiliation: Hovensa LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 10

Comment: Process Heaters in the refining industry (and in other industries as well) must be designed for the process that they support. One key variable is temperature, which can vary in different processes by 600 or more degrees because of the heat needed for a particular type of process. For example, a delayed coking unit operates at relatively high temperatures to thermally crack heavy residuals into lighter products. Conversely, a Platformer (Catalytic Reforming) uses a very unusual heater design tailored to the catalytic reforming process and also incorporates smaller heaters between reactors. Design differences in process heaters to support the functions of different units lead to differences in residence time and temperature. Another design difference that changes CO emissions is whether air preheat is used. Air preheat improves energy efficiency, but raises NOx emissions. The NOx/CO tradeoff is well known in literature:

For these reason, it is likely that many (if not all) of the boilers in the database used to set the CO floor (e.g. DAK9) are not controlled for NOx and use standard burner designs. Similarly, higher excess oxygen levels reduce CO but increase energy usage, increasing CO_2 emissions, working directly contrary to a provision in the Boiler MACT intending to improve energy efficiency. [Footnote 9: Confirmed orally with persons knowledgeable about the DAK facility.]

Response: See response to comment EPA-HQ-OAR-2002-0058-2912, excerpt 2 for separate subcategories for process heaters and boilers.
See response to comment EPA-HQ-OAR-2002-0059-2702.1, excerpt 68 for additional subcategory to distinguish between units with low NOx burners.

Commenter Name: Roy W. Wood
Commenter Affiliation: Eastman Kodak Company
Document Control Number: EPA-HQ-OAR-2002-0058-2917.1
Comment Excerpt Number: 12

Comment: Kodak urges EPA to create a "limited use" category for existing fuel oil-fired auxiliary boilers that requires a work practice standard in lieu of an emission standard. Many auxiliary boilers at industrial facilities are greater than 10 million Btu/hour and burn fuel oil, but operate for only limited time periods to provide steam and/or electricity when a primary boiler unit is not operational. Kodak's Eastman Business Park site in Rochester, New York has four such units which are only operated when one of the larger coal fired units is off-line. Since they are frequently not needed for months at a time, they are also fired for short periods on a monthly basis to maintain operational readiness. Auxiliary boilers typically operate less than 10% of their annual capacity factor (less than 870 hours per year). Requiring a work practice standard (similar to that allowed for existing natural gas boilers) would effectively reduce emissions of HAP for this category of boilers. Expensive boiler modifications to switch fuel to natural gas or to meet emission standards will not result in significant HAP reductions. For these reasons Kodak urges EPA to create a "limited use" category that applies a work practice standard in lieu of an emission standard for fuel oil-fired auxiliary boilers located at major sources of HAP. This category would apply only where these sources are limited to 870 hours per year as a federally enforceable permit condition.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Christopher S. Colman
Commenter Affiliation: Hovensa LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 14

Comment: For purposes of CO emissions, boilers fall into two major types—field erected and package boilers. Package boilers are smaller and are size limited so that they can be shipped and installed on site. Package boilers are particularly important to island based facilities such as HOVENSA because they can be shipped to islands and installed without as much construction, which is a much higher cost in the Virgin Islands as will be discussed below. As these boilers reach their maximum size (~250 mmbtu/hr), the firebox becomes constrained causing CO to increase at higher loads. Larger boiler designs may also have a vertical air flow regime which allows for the incorporation of flue combustion or overfire air, which have the effect of lowering NOx and CO. As is the case with many NSPS rules, we recommend that boilers be subcategorized by size. Boilers at refineries, particularly those without natural gas, may be expected to have higher load variability as is the case with process heaters.

Response: See response to comment EPA-HQ-OAR-2002-0058-2818.1, excerpt 18 for subcategorizing according to heat input size.

Commenter Name: Wayne J. Galler and Deborah A. Phillips
Commenter Affiliation: Georgia Industry Environmental Coalition, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2882.1
Comment Excerpt Number: 15

Comment: GIEC suggests that EPA develop a separate subcategory for "limited use" boilers with no numerical emission limits. In the 2004 Boiler MACT Rule, EPA treated boilers that operated with average capacity factors of 10% or less separately from all other boilers. Many industrial operations utilize "limited use boilers for cold startups and intermittently for short periods of time such as for facility outages, or as a backup boiler that runs when other units are being repaired, or a peaking unit used to supplement electric generation during particularly hot summer days_ Compared to most boilers, these units spend a far greater percentage of their time starting up and shutting down. As a result, their emissions profiles differ from sources which operate in efficient steady-state manners_ For example, they are likely to experience higher CO levels as the boiler heats up due to incomplete combustion. Similarly, many pollution control technologies are either difficult to use or ineffective during startup and shutdown periods and would be cost prohibitive to install and use for only short periods of time during a year These are just the sort of "class" and "type" distinctions which merit consideration for subcategorization under Section 112(d)(2) of the Act.

EPA provided a separate category for emergency use engines under the. RICE MACT (40 CFR 63 Subpart ZZ77-March 3, 2010) with work practice standards in lieu of numerical emission limits. GIEC believes EPA should follow a similar path for "limited use" boilers under the final Boiler MACT Rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Christopher S. Colman
Commenter Affiliation: Hovensa LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 17

Comment: Because design and operating differences are relevant to emissions of HAPS from refinery process heaters, particularly as regards CO and steady state operations, they should be separately subcategorized. This approach is exactly that used by EPA in proposing a separate work practice for metal finishing furnaces:

"These individual burners are operated to cycle on and off to maintain the proper temperatures throughout the various zones of the process heater. Thus, due to their design, these process heaters rarely operate in a steady-state condition due to burners constantly starting up and shutting down. This results in emissions characteristics different from the process heaters used in other industries."

Our comment is also consistent with input from SERs. ("SERs commented that EPA should subcategorize based on fuel type, boiler type, duty cycle, and location")

Response: See response to comment EPA-HQ-OAR-2002-0058-2912, excerpt 2 for separate subcategories for process heaters and boilers.

Commenter Name: Richard L. Killion
Commenter Affiliation: Babcock and Wilcox Power Generation Group
Document Control Number: EPA-HQ-OAR-2002-0058-2722.1
Comment Excerpt Number: 17

Comment: MACT emission limit subcategories for existing equipment should take into consideration the existing combustion technologies of the existing equipment.

However, new equipment should be subdivided by fuel type only. Having limits on new units subdivided into combustion technology precludes the development of new technologies that may not exist today, and could inadvertently encourage technologies that allow higher emissions.

Response: Subcategories were developed to consider design and operating conditions of various types of boilers and process heaters. Although combustor design varies, many of the designs are related to the type of fuels combusted at the units and were not selected to promote ineffficient technologies. See the preamble for how EPA allowed units to switch subcategories. EPA determined that combustor-designed based subcatetoreis are appropriate.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 18

Comment: Electric utilities that operate auxiliary boilers will be subject to the IB MACT rule because they are not steam generating units that produce electricity. Auxiliary boilers operate infrequently normally during plant startups and combust either natural gas or distillate fuel. As a result, the HAP emissions from the auxiliary boilers are exceedingly low and do not pose any risk to public health.

Under the proposed rule, gas-fired auxiliary boilers are subject to work practice standards requiring an annual tune-up. By contrast, the proposed IB MACT rule requires oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not produce environmental benefits.

EPA should create a limited use subcategory for boilers combusting distillate fuel that would subject those units to the same work practice standards as gas-fired units. The limited use subcategory should have a 10% capacity factor threshold. Eligibility for this subcategory would be determined based on 10% of the maximum hourly heat input of the boiler multiplied by 8760 hours per year.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Chris Korleski
Commenter Affiliation: Ohio EPA

Comment Excerpt Number: 18

Comment: The proposed rule defines a single emission limit applicable by boiler type over a very broad capacity range of either greater or less than 10 mmBTU/hr. It has been our experience that there are distinct combustion characteristics for the same type of boiler at additional capacity thresholds that may affect the emissions of organic HAP emissions (refer to discussion on carbon monoxide emission limit). For example, liquid fuel-fired boilers in the range of 100 to 150 mmBTU/hr or larger are multiple burner systems, whereas smaller boilers are typically single burner systems. In similar fashion, differences in combustion configuration are expected for process heaters through different size ranges and by types of application. Another example is coal-fired stoker boilers which in range in size from 50 mmBTU/hr to over 500 mmBTU/hr. This difference in stoker boiler size greatly affects the characteristics of combustion, the rate of heat absorption, boiler residence time, etc., all of which affect combustion characteristics of the sources. Clear distinctions in combustion characteristics for different types of boilers are identified in EPA's documents of Achievable Control Technology for NOx controls. The same concept should apply to the MACT standards.

Response: The EPA sees no legal justification establishing a separate subcategory based on the size of the unit. In the final rule EPA did not develop a separate subcategory for small boilers but instead identified that units less than 10 mmBtu/hr qualify for a work practice under Section 112(h) of the CAA. See the preamble for further discussion of how the threshold of 10 mmBtu/hr was selected for the work practice standard.

The EPA does not see justification for creating a separate subcategory for medium sized units. The EPA does not view medium sized boilers as being different than larger boilers. Combustor designs, applicable air pollution control devices, fuels used, and operation are similar for large and medium units. While actual pollution controls used and monitoring equipment may be different, the CAA does not allow EPA to subcategorize on these parameters.

Comment: Within the universe of potentially affected units, many are operated as stand-by or redundant capacity, reserved for use during periods when circumstances mandate the need to provide steam in order to preserve conditions within the distribution system. These boilers are often equipped with coils to maintain internal metal temperatures, as well as boiler drum pressure and temperature, to allow for quick response following the combustion safety purge.

IDEA recommends that EPA provide for these sorts of operating scenarios in the final rule by establishing a limited use subcategory for liquid or gas 2 units based on 10% annual capacity factor or 1,000 hours/year as a threshold. These units operate for short periods of time during the year and as such may experience relatively little SSM. The short run times would likely exacerbate the effect of startup/shutdown on 30 day averages. Because limited use units do not operate regularly, their emissions differ from average boilers operating for longer periods of time or near their design capacity.

EPA has recognized that "units operate most efficiently when operated at or near their design capacity." 75 FR 32023-24. Based on their operating schedule, limited use units may or may not operate at or near their design capacity, but if they do it is for limited periods of time. Considering this, limited use units may operate for a greater percentage of their total operating time inefficiently as compared to steady state units operating near design capacity.

In addition, the short operating times of limited use units results in difficulties in effectively controlling emissions. As EPA noted in a 2004 response to comments document, based on the operating schedules of limited use units the agency could not identify a control technology for controlling organic HAP emissions. See EPA, Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP, at 67 (Feb. 25, 2004). Considering these differences based on the operating schedule of limited use units, EPA should establish a subcategory for limited use boilers and process heaters. The subcategory should be defined to include units with a capacity utilization factor of 10 percent; or, by a 1,000 hours operating per year threshold.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: 1. General
HOVENSA, as an island based refinery, has unique configurations and constraints that mainland refineries do not. One of the key constraints is that HOVENSA cannot physically access natural gas pipelines. This makes the burning of liquid fuels (produced on site) an unavoidable part of doing business in St. Croix, as EPA observes in the rule preamble. There are many other constraints, either deriving from oil burning or remote location that affect the design, configuration and operation of heaters and boilers at HOVENSA and other non-continental refineries, such that their unique characteristics merit a specific subcategory. Moreover, the dual fired heaters used at HOVENSA are a very different design than EPA apparently contemplated in establishing subcategories and this design also affects the combustion chamber design. We urge EPA to adopt a remote /island location subcategory, as it did in the CISWI rule for smaller remote facilities, because of these inherent design and operating constraints.

Response: See preamble for discussion of a non-continental unit subcategory.

Comment: CAA §112(c)(1) instructs EPA to establish “categories and subcategories” of sources for regulation under Section 112. CAA §112(d)(1) then further provides that EPA “may distinguish among classes, types and sizes of sources within a category or subcategory” when establishing MACT standards. These provisions vest EPA with the clear authority to group like units for purposes of establishing emissions limitations. EPA's subcategorization decisions, however, must turn on legitimate "class" "type" or size" distinctions as required by §112(d).

The legislative history explains what Congress meant when it authorized EPA to distinguish among sources by "class" "type" or "size." The relevant Senate Report indicates that EPA should: [T]ake into account factors such as industrial or commercial category, facility size, type of process and other characteristics of sources which are likely to affect the feasibility and effectiveness of air pollution control technology. Cost and feasibility are factors which may be considered by the Administrator when establishing an emission limitation for a category under Section 112 . . . where a group of sources may share the characteristics of other sources in the category, the Administrator may establish subcategories for such sources. S. REP. NO. 228, 101st Cong., 1st Sess. 166 [JA 1426] (emphasis added).

That language has two key implications. First, it confirms that Congress' use of the broad concepts of "class" "type" or "size" was meant to allow subcategorization based on (and require consideration of) a broad array of factors. That is particularly true given Congress' open-ended statement that EPA should consider "other characteristics of sources" when grouping them for purposes of establishing emissions limits. Second, this statement confirms that, while cost issues alone may not be sufficient to require subcategorization, costs are relevant to subcategorization decisions. See also, Id. (indicating that subcategorization "wholly on economic grounds" is inappropriate) (emphasis added). By clarifying that individual facilities may not be granted categorical waivers "based on assertions of extraordinary economic effect," id., the Senate Report confirms that the threat of severe economic consequences on a subgroup sharing other common attributes supports subcategorization.[A related House Report confirms that cost implications are relevant to all facets of MACT regulation by providing that "MACT is not intended to require unsafe control measures, or to drive sources to the brink of shutdown." HOUSE REP. NO. 101-490, Part 1, at 328. Preliminary of control technology, (2) effectiveness of control technology, and (3) costs of control. Where those factors are present, subcategorization is warranted.] Thus, §112(d)(2) authorizes (and requires) EPA to consider differences in "commercial category, facility size, type of process and other characteristics" that may affect: (1) feasibility of control technology, (2) effectiveness of control technology, and (3) costs of control. Where those factors are present, subcategorization is warranted.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Comment: 2. No Natural Gas-Oil Burning Required

The primary fuel burned at HOVENSA, as noted above, is the gas produced by the different process units. Because there is no natural gas pipeline, HOVENSA has no choice but to burn liquid fuels to maintain a fuel/heat balance. HOVENSA has no outlet or storage for the hydrocarbon gas it generates and so this fuel gas must be burned in onsite combustion units. A refinery will burn all of the fuel gas it produces, but by design, the fuel gas produced at a refinery is less than the energy required to operate the refinery, otherwise the refinery would be required to flare the fuel gas.
The characteristic that HOVENSA and other remote oil burning refineries share is that they do not have a natural gas supply, which is functionally equivalent to refinery fuel gas from an operational and heater/boiler design perspective. The result is that HOVENSA must supplement the fuel gas with residual or distillate fuel oil. Because of their very different characteristics, fuel oils cannot be combusted in the same burner elements as gas fuels. They can be simultaneously combusted in a burner equipped with both oil and gas burner elements, which changes combustion dynamics and is an operating mode not apparently recognized by EPA as discussed below. The inability to obtain natural gas removes the option of being able to burn only gaseous fuels as a compliance strategy and burning fuel oil as a supplemental fuel makes complying with this proposed MACT unfairly onerous for HOVENSA and similarly situated major facilities.

Response: See preamble for discussion of a non-continental unit subcategory.

Comment: Currently, the proposed rule does not have a subcategory for backup or emergency use boilers. These boilers do not operate on a regular schedule and typically operate for only short periods of time. As a result, emissions profiles for these boilers can vary significantly from those of a similar boiler operating in a steady state. See id. at 32,023 ("Combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit's load (steam production) decreases."). Given their short run times, there are also technological limitations on how effectively emissions from these units can be controlled, particularly for organic HAP emissions. See Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 67 (February 25, 2004) ("[W]e could not identify any control technologies that would reduce organic HAP emissions [for limited use boilers]. Therefore, while larger units may emit more than smaller units, we have not identified any appropriate technology or method that could be used to reduce organic HAP emissions."). Finally, since "limited use boilers, when called upon to operate, must respond without failure and without lengthy periods of startup,"[24 National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed.Reg. 55,218, 55,232 (September 13, 2004).] a significantly larger percentage of their annual operation is be devoted to maintenance and readiness testing than other commercial, industrial, or institutional boilers. These differences justify the creation of a limited use category for emergency and backup boilers.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: The Limited Use Subcategory Should be Based on a Capacity Utilization of 10%. For CI RICE, "[t]here is no time limit on the use of emergency stationary engines in emergency situations." Id. at 9654. This is a reasonable provision, since an emergency RICE must continue to operate as long as an emergency persists. This provision should similarly apply to limited use boilers. In addition, however, EPA recognized in the final CI RICE MACT rule that these units also need to operate in other, non-emergency situations, including for maintenance and participation in demand response programs. As a result, EPA allocated time within each operating year (100 hours) for emergency CI RICE to operate in non-emergency situations for what EPA referred to as "maintenance checks and readiness testing." Id. at 9654. In addition, EPA allocated 50 hours of each unit's maintenance and readiness time for other non-emergency uses, including at least 35 hours for non-financial uses and up to 15 hours for participation in emergency demand response programs, where the unit would be needed to provide power to a "regional transmission organization or equivalent balancing authority" and the "transmission operator has determined there are emergency conditions that could lead to a potential electrical blackout." Id. Examples of such conditions were also provided by EPA, including "unusually low frequency, equipment overload, capacity or energy deficiency, or unacceptable voltage level." Id.
Given the importance of demand response programs to averting blackouts and other emergencies, the State of Ohio recently went even further, expanding the definition of "emergency" in its permit-by-rule exemptions from MACT for emergency generators less than 50 horsepower to include:Conditions where a regional transmission organization notifies electric distributors that an emergency exists or may occur and it is necessary to implement emergency procedures for voluntary load curtailments by customers within Ohio, in response to unusually low frequency, equipment overload, capacity or energy deficiency, unacceptable voltage levels, or other emergency conditions leading to a potential electrical blackout. . . . Proposed Amendment to OAC 3745-31-03 (June 7, 2010); Executive Order 2010-07S (June 7, 2010) (adopting proposed amendment).

As stated by Governor Strickland, "[i]n the event of an electrical grid failure that could result in widespread electrical blackouts, Emergency Load Response Programs allow emergency generator operators to temporarily utilize their generators without the need to obtain a permit to help prevent those blackouts. Allowing the use of emergency generators in such circumstances protects public health and welfare." Executive Order 2010-07S at ¶4. Further, Ohio has exempted all emergency electrical generators operating less than 500 hours per rolling 12-month period from obtaining a permit to install. See Proposed Amendment to OAC 3745-31-03.

For these same reasons, EPA should consider both the necessity of maintenance and readiness testing, as well as participation in emergency demand response programs and other "non-emergency" uses in setting the parameters for a limited use subcategory. While limits based on hours of operation like those used in the CI RICE MACT are one option, another and potentially easier standard to administer would be to rely on capacity utilization. Boilers, unlike RICE, cannot start up or shut down quickly, making it difficult for boiler operators to run a boiler for only a set number of hours. An hours-of-operation limit, therefore, would be less practical than a limit based on capacity utilization. Moreover, as EPA noted in the Proposed Rule, some emissions from boilers are not dependent on operating parameters such as hours operated, but rather on the fuel consumed. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed.Reg. at 32017 (discussing fuel-dependent HAP). A capacity utilization factor of 10% was chosen for the previous boiler MACT final rule as the best means of defining a limited use unit. See National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed.Reg. at 55223. This definition is equally appropriate for the current rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: 6. Fuel Availability
HOVENSA has only one practical supplier of fuel oil, which is the refinery itself. The HAP metals content of the fuels particularly for residual fuel oil, is a direct result of the crude slate used at HOVENSA. That is because residual fuel oil (except for slurry oil, production of which is discussed above) is typically the bottom fractions from either atmospheric crude distillation units, vacuum units or visbreakers. These bottom fractions have high boiling points and, except for mercury, metals in the crude oil will tend to stay with these fractions. At HOVENSA, residual fuel used in heaters and boilers, which must be low sulfur residual fuel oil (<1% S, and expected to be required to be <.5% in the future, eliminating use of low metals slurry oil), is primarily produced in Crude and Vacuum units on the west side of the HOVENSA refinery from relatively low sulfur crude. However, other units (including those used to process heavy sour crudes) may contribute to the residual oil blending pool, which may contribute blending components that are higher in metals. 31
HOVENSA processes a large number of crude types as compared to state-side refineries because of its island location:

There is no crude supply pipeline to St. Croix/HOVENSA. Many mid-continent refineries are tied to production from a specific area and see fewer crude types.

All crude is supplied by ship and the physical size of crude ships is limited by what is available in the world and manageable by load/discharge ports

Unless located in close geographic location to the Caribbean, the crude ship travel time can be longer than the refinery processing time for the amount of crude on a ship

The physical collection rate of the specific crude out of the ground can be less than the actual processing rate at HOVENSA

The commercial availability of specific crude types in the world in the quantities necessary for HOVENSA

The metals content varies substantially between different crude oils that are presently being used at the refinery to produce residual fuel oil. (See submittal for table of trace metals in various crudes).

Many other types of crude have historically been processed at HOVENSA, which are equally likely to show metals variability. Although HOVENSA does not presently have data on mercury in its crude oils or residual fuel oils, an excellent paper by Wilhelm and Spitz, Impact of Mercury on Crude Oil Quality, outlines expected variations in mercury content in various crude oils from Alberta, reporting orders of magnitude differences, as do other papers by this same author. Even light sweet crudes can have high mercury levels; Belanak from Indonesia has been reported to have 100 to 350 ppb. The sampling data in Attachment 2 shows nickel content for .3%S residual fuel to be approximately 31- 41 ppm, which is somewhat higher than nickel content of other .3%S resides in this database. HOVENSA does not even have the theoretical possibility to seek out lower metal fuels from other suppliers and must use what is produced or available at the refinery. (See submittal for sampling data)

EPA discussed in the preamble the Brick MACT case which considers this issue:
The majority opinion in the Brick MACT case does not address the
possibility of subcategorization to address differences in the HAP content of raw materials. However, in his concurring opinion Judge Williams stated that EPA's ability to create subcategories for sources of different classes, size, or type (CAA section
112(d)(1)) may provide a means out of the situation where the floor standards are achieved for some sources, but the same floors cannot be achieved for other
sources due to differences in local raw materials whose use is essential. (Id. At 884)
We believe that this opinion clearly allows EPA to establish a subcategory for remote/island facilities in this rule because they have the same potential issue of being unable to meet the Boiler MACT rule because of the local fuels available.

[Footnote 33: As noted above, mercury does not necessarily concentrate in residual fuel oil, because of its relative volatility.]
[Footnote 34: Platts Oilgram News, July 11, 2005]
[Footnote 35: HOVENSA plans on additional sampling. As noted above, HOVENSA anticipates that it will be prohibited from combusting low metals slurry oil in the future because of its sulfur content.]

Response: See preamble for discussion of a non-continental unit subcategory.

Comment Excerpt Number: 37

Comment: One additional subcategory that merits consideration is for “limited use” units. While the prior Boiler MACT rule treated units with average capacity factors of 10% or less separately, the proposed rule does not continue that approach. Instead, it presumes that limited use units are just like those operated full-time which burn a similar fuel. Limited use sources operate intermittently and for shorter periods of time (e.g., a backup hospital boiler that runs when other units are being fixed or a peaking unit used to supplement electric generation during particularly hot summer days). Compared to most boilers, these units spend a far greater percentage of their time starting up and shutting down. As a result, their emissions profiles differ markedly from sources which operate in efficient steady-state manners. For example, they are likely to experience higher CO levels as the boiler heats up due to incomplete combustion. Similarly, many pollution control technologies are either difficult to use or ineffective during startup and shutdown periods. These are just the sort of “class” and “type” distinctions which merit consideration for subcategorization under §112(d)(2). Given the limited and sporadic operation of emergency and backup boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should be limited by work practices in lieu of an emission floor.

The limited use subcategory adopted in EPA’s 2004 Boiler MACT final rule should be carried forward to the proposed rule.

The previous version of EPA’s Boiler MACT recognized that boilers used for emergencies or as backup boilers should be placed in a subcategory due to the limited and unscheduled nature of their use. See National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. 55218, 55232 (September 13, 2004). EPA recognized that “[t]he boiler database indicates that these infrequently operated units typically operate 10 percent of the year or less,” however, “[t]hese limited use boilers, when called upon to operate, must respond without failure and without lengthy periods of startup.” Id. Continued recognition of this subcategory is both supported by recent EPA action and practically justified.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: A limited use subcategory is supported by EPA's recent similar treatment of emergency and black start compression ignition engines.

In March of this year, EPA provided a similar subcategory in its final rule promulgating national emission standards for existing compression-ignition reciprocating internal combustion engines ("CI RICE") with a site rating of less than or equal to 500 brake horsepower. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. 9648 (March 3, 2010).

In that Rule, EPA recognized that stationary existing CI RICE should be divided into non-emergency and emergency categories "in order to capture the unique differences between these types of engines." Id. at 9650. Like the limited use boilers described in EPA's September 13, 2004 rule, EPA recognized that these emergency CI RICE are required to operate infrequently and for relatively short periods of time and must be kept in working order during prolonged periods of time when they are not operating.

EPA cited as justification for its emergency unit subcategorization an earlier memorandum titled Subcategorization and MACT Floor Determination for Stationary Reciprocating Internal Combustion Engines ?500 HP at Major Sources, Docket No. EPA-HQOAR-2008-0708-0006 (January 21, 2009). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 74 Fed. Reg. 9698, 9705 (March 5, 2009). This memorandum, in turn, incorporated by reference the rationale found in the memorandum Subcategorization of Stationary Reciprocating Internal Combustion Engines ?500 HP, Docket No. EPA-HQ-OAR-2005-0030-0012 (May 15, 2006), which enumerated four reasons for creating a subcategory for emergency CI RICE:

1. Emergency use units are used when electric power from the local utility is interrupted or becomes unreliable. The duration of the power outages is entirely beyond the control of the source, and, when they do occur (except in the case of a major catastrophe) they rarely last more than a few hours, often only a few minutes.

2. Emissions from these units are expected to be low on an annual basis; emissions occur only during emergency situations or for a very short time to perform maintenance checks and operator training. State and local regulators generally have not required emission controls for emergency power/limited use units.

3. Add-on catalytic control devices that are most applicable to reduce HAP from stationary RICE would be less effective on an annual basis for emergency use units, since emergency use units generally operate for brief periods. Therefore, a greater percentage of the emergency use units' operation, as compared to operation of peaking or baseload engines, will occur during catalyst warm-up, when the catalyst's effectiveness will be lower.

4. Emergency use units operate for very few hours per year. A survey conducted by the California Air Resources Board indicated that emergency engines are operated about 30 hours

per year. Also, the National Fire Protection Association requires 30 minutes per week (27 hours per year) to maintain and test emergency engines. The recently finalized Airborne Toxic Control Measure in California allows districts to approve up to 100 hours per year for maintenance and testing of emergency engines.

Id. at 5-6. [Footnote: While these criteria focus on an "emergency use" subcategory, it is important to note that the limited duration of the use, not the purpose for using the RICE is the key issue. For example, the same rule also creates a subcategory for "black start" engines (engines used to start a turbine generator), which operate during both "emergency and high demand days." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. 55218 at 9662.]

These same criteria justify the establishment of a limited use Boiler MACT subcategory. First, limited use boilers, whether used as backup or emergency use boilers, are put into service only during unexpected failures of the main boiler or "when electric power from the local utility is interrupted or becomes unreliable" both of which are events "entirely beyond the control of the source." Id. at 5. Second, because of their limited use during the year, "[e]missions from these units are expected to be low on an annual basis." Id. Third, for this same reason, a greater percentage of a limited use boiler's annual operations will be during startup and shutdown, when emissions controls are less effective. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32023. Finally, like emergency CI RICE, limited use boilers operate for only a small portion of the year, typically "10 percent of the year or less." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. at 55232.

Like emergency and black start CI RICE, emergency and backup boilers should be placed into a subcategory that recognizes the unique challenges that would be faced monitoring and controlling emissions from these units.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Alicia Oman
Commenter Affiliation: National Association of Manufacturers
Document Control Number: EPA-HQ-OAR-2002-0058-2845.1
Comment Excerpt Number: 39

Comment: Limited use boilers cannot practically demonstrate compliance with standards set relying on continuously operating units.

In addition to the unique operating characteristics of limited use boilers, there are practical reasons for creating a limited use subcategory as well. As noted by Judge Williams in Sierra Club v. EPA, "Section 112(d)(1) authorizes the Administrator to 'distinguish among classes, types, and sizes of sources within a category or subcategory' . . . . [O]ne legitimate basis for creating additional subcategories must be the interest of keeping the relation between 'achieved' and 'achievable' in accord with common sense and the reasonable meaning of the statute." Sierra Club v. EPA, 479 F.3d 875, 884-85 (D.C. Cir. 2007) (Williams, J., concurring).

Without subcategorization for limited use boilers, these infrequently operated units will need to comply with the same emission limits set by units that operate on a continuous bases. As noted above, "combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit's load (steam production) decreases." National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32023. Limited use boilers will therefore be operating for a significantly greater percentage of their time during periods of inefficient operation.

While EPA has already attempted to address this problem through the current MACT floor analysis by addressing the reduced efficiency of load-following units through allowances for variability. [Footnote: See MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 9-10 (April 2010).] this problem is further amplified for limited use boilers, which EPA did not address in its MACT floor analysis, due to EPA's decision to include periods of startup and shutdown in determining compliance with MACT. As found by EPA, this was justified because "the standards that we are proposing are daily or monthly averages. Continuous emission monitoring data obtained from best performing units, and used in establishing the standards, include periods of startup and shutdown. Boilers, especially solid fuel-fired boilers, do not normally startup and shutdown more the [sic] once per day. Thus, we are not establishing a separate emission standard for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." Id. at 32013. [Footnote: Continuous emission monitoring data is not available for all pollutants in the database. To the extent that emission limits are based on stack test data that does not consider SSM events, emission information based on an operator's knowledge and engineering calculations can be used to incorporate SSM variability into the MACT Floor analysis.] Moreover, EPA found that "[p]eriods of startup, normal operations, and shutdown are all predictable and routine aspects of a source's operation." Id. Neither of these findings reasonably applies to emergency or backup boilers. First, as discussed above, emergency and backup boilers cannot practically make measurements over a monthly average given their limited utilization. Second, emergency and backup uses are by definition neither predictable nor routine.

By their very nature, emergency and backup boilers must spend a larger percentage of time in startup, shutdown, or other reduced-efficiency operating conditions than either base-loaded or load-following units. EPA should not require limited use boilers to comply with standards set by the best operated of these more efficient units.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: The limited use subcategory should be based on a capacity utilization of 10%.

For CI RICE, "[t]here is no time limit on the use of emergency stationary engines in emergency situations." Id. at 9654. This is a reasonable provision, since an emergency RICE must continue to operate as long as an emergency persists. This provision should similarly apply to limited use boilers. In addition, however, EPA recognized in the final CI RICE MACT rule that these units also need to operate in other, non-emergency situations, including for maintenance and participation in demand response programs. As a result, EPA allocated time within each operating year (100 hours) for emergency CI RICE to operate in non-emergency situations for what EPA referred to as "maintenance checks and readiness testing." Id. at 9654. In addition, EPA allocated 50 hours of each unit's maintenance and readiness time for other non-emergency uses, including at least 35 hours for non-financial uses and up to 15 hours for participation in emergency demand response programs, where the unit would be needed to provide power to a "regional transmission organization or equivalent balancing authority" and the "transmission operator has determined there are emergency conditions that could lead to a potential electrical blackout." Id. Examples of such conditions were also provided by EPA, including "unusually low frequency, equipment overload, capacity or energy deficiency, or unacceptable voltage level." Id.

Given the importance of demand response programs to averting blackouts and other emergencies, the State of Ohio recently went even further, expanding the definition of "emergency" in its permit-by-rule exemptions from MACT for emergency generators less than 50 horsepower to include:

Conditions where a regional transmission organization notifies electric distributors that an emergency exists or may occur and it is necessary to implement emergency procedures for voluntary load curtailments by customers within Ohio, in response to unusually low frequency, equipment overload, capacity or energy deficiency, unacceptable voltage levels, or other emergency conditions leading to a potential electrical blackout. . . .

Proposed Amendment to OAC 3745-31-03 (June 7, 2010); Executive Order 2010-07S (June 7, 2010) (adopting proposed amendment). As stated by Governor Strickland, "[i]n the event of an electrical grid failure that could result in widespread electrical blackouts, Emergency Load Response Programs allow emergency generator operators to temporarily utilize their generators without the need to obtain a permit to help prevent those blackouts. Allowing the use of emergency generators in such circumstances protects public health and welfare." Executive Order 2010-07S at ¶4. Further, Ohio has exempted all emergency electrical generators operating less than 500 hours per rolling 12-month period from obtaining a permit to install. See Proposed Amendment to OAC 3745-31-03.

For these same reasons, EPA should consider both the necessity of maintenance and readiness testing, as well as participation in emergency demand response programs and other “non-emergency” uses in setting the parameters for a limited use subcategory. While limits based on hours of operation like those used in the CI RICE MACT are one option, another and potentially easier standard to administer would be to rely on capacity utilization. Boilers, unlike RICE, cannot start up or shut down quickly, making it difficult for boiler operators to run a boiler for only a set number of hours. An hours-of-operation limit, therefore, would be less practical than a limit based on capacity utilization. Moreover, as EPA noted in the Proposed Rule, some emissions from boilers are not dependent on operating parameters such as hours operated, but rather on the fuel consumed. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 32017 (discussing fuel-dependent HAP). A capacity utilization factor of 10% was chosen for the previous Boiler MACT final rule as the best means of defining a limited use unit. See National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. at 55223. This definition is equally appropriate for the current rule.

Comment: EPA has broad discretion to establish subcategories of sources. Section 112 provides EPA with explicit authority "to establish subcategories under this section , as appropriate." [70 Fed. Reg. 59462 (October 12, 2005).] Indeed, section 112 establishes a presumption in favor of the creation and modification of categories and subcategories in the course of the Agency’ regulatory program, by mandating that EPA ‘shall from time to time, but no less often than every 8 years, revise, if appropriate, in response to public comment or new information, a list of all categories and subcategories of major sources."[Clean Air Act section 112 (c)(1); see also section 112 (c)(5) ("... the Administrator may at any time list additional categories and subcategories of sources."] section 112(c)(1). The fact that section 112 empowers EPA to establish subcategories without any limiting criteria confers a broad grant of authority. [Consumer Federation of America v. U.S. Dept. of Health and Human Services, 83 F.3d 1497 (D.C. Cir. 1996) (interpreting the phrase "as appropriate" in a more limiting statutory mandate as conferring substantial discretion).] Nothing in the Act or applicable case law suggests otherwise.

While EPA has nearly unfettered discretion to create subcategories as appropriate, the Act provides ample authority for EPA to distinguish among groups of sources within a source category or subcategory in setting a MACT standard. The statute provides that EPA "may distinguish among classes, types and sizes of sources within a category or subcategory" when establishing MACT standards.[42 U.S.C. section 7412(d)(1).] Congress" use of the broad terms "class," "type," and ‘size" shows that EPA is intended to have broad discretion in the appropriate factors that warrant distinguishing among sources, and EPA's proposed subcategories fall squarely within the meaning of "types" and 'sizes."

It is a well-established canon of statutory construction that courts "give the words of a statute their ordinary, contemporary, common meaning, absent an indication Congress intended them to bear some different import."70 [Williams v. Taylor, 529 U.S. 420, 431, 120 S.Ct. 1479, 1487-88, 146 L.Ed.2d 435 (2000).] The term "class" is typically defined to mean "a group, set or kind marked by common attributes or a common attribute."[Webster's Third New International Dictionary Unabridged (1993).] "Type" is defined as "qualities common to a number of individuals that serve to distinguish them as an identifiable class or kind,"[Id]. further clarifying that ""[t]ype", "kind" and 'sort" are usually interchangeable" and that ""kind" in most uses is likely to be very indefinite and involve any criterion of classification whatsoever." To the extent that EPA may distinguish among sources within a category or subcategory on the basis of "any [reasonable] criterion of classification whatsoever," and may create subcategories as appropriate, the CAA strongly supports EPA's authority to create subcategories of industrial boilers as proposed.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Comment: The legislative history makes clear that Congress intended EPA to distinguish among classes, types and sizes of sources in three circumstances: when differences among sources affect (1) the feasibility of air pollution control technology; (2) the effectiveness of air pollution control technology; and (3) the cost of control.

The Senate Report clarifies that the Administrator should:

...take into account factors such as industrial or commercial category, facility size, type of process and other characteristics of sources which are likely to affect the feasibility and effectiveness of air pollution control technology. Cost and feasibility are factors which may be considered by the Administrator when establishing an emission limitation for a category under section 112. The proper definition of categories, in light of available pollution control technologies, will assure maximum protection of public health and the environment while minimizing costs imposed on the regulated community. However, in limited circumstances where a group of sources may share the characteristics of other sources in the category, the Administrator may establish subcategories for such sources.[S. Rep. No. 228, 101st Cong., 1st Sess. 166].

Thus, in the view of the Senate, the standard for establishing categories and subcategories is essentially the same, although the Administrator is cautioned not to make too rampant use of subcategories.

The House Report similarly provides:

EPA may distinguish among classes, types and sizes of sources within a category or subcategory. . . . In the determination of MACT for new and existing sources,

consideration of cost should be based on an evaluation of the cost of various control options. The Committee expects MACT to be meaningful, so that MACT will require substantial reductions in emissions from uncontrolled levels. However, MACT is not intended to require unsafe control measures, or to drive sources to the brink of shutdown. [House Rep. No. 101-490, Part 1, at 328.]

In sum, while Congress intended the MACT program to achieve significant emissions reductions, it also intended EPA to be cognizant of the costs of control, and to ensure that the program did not cause significant economic hardship. One primary mechanism for achieving this goal is through the use of subcategories, which enables the Agency to account for the fact that distinctions among classes, types and sizes of sources may have a very real impact on the feasibility of a given control technology, the effectiveness of that control technology, and the cost of control.

Comment: The only case to interpret the "classes, types and sizes" language supports this interpretation. Sierra Club v. Costle [657 F.2d 298 (D.C. Cir. 1981).] recognized the broad discretion this language confers on EPA to create what in effect are subcategories of sources with differentiated emission standards. This decision interpreted identical statutory language found in the New Source Performance Standards (NSPS) provisions of section 111 of the CAA. Under the "classes, types and sizes" language, the Sierra Club court upheld a variable NSPS SO2 reduction requirement that was tied to a source’s existing SO2 emissions levels which, in turn, depended on the sulfur content of the facility’s fuel. The court noted that "[t]he required finding that must underlie a variable standard is much broader than a mere determination that uniformity is not achievable. Rather, EPA has the discretion to vary the standard upon finding that such a departure (from uniform control) does not undermine the basic purposes of the Act." [Id. at 321.]

On this basis, the court expressly upheld EPA’s subcategorization of coal-fired power plants based on the sulfur content of fuel, finding that "[c]ertainly the text of the statute nowhere forbids a distinction based on sulfur." [Bragdon v. Abbott, 524 U.S. 634, 645 (1998).] More generally, the Sierra Club decision confirms EPA’s discretion to set differentiated emissions standards for groups of sources within a category – i.e., for subcategories – even in instances where the strictest standard may be achievable by all sources.

The House Report further provides that "Nothing in this language authorizes the establishment of a category based wholly on economic grounds, nor is there any implication that individual facilities may be granted categorical waivers ... based on assertions of extraordinary economic effect." [id] In other words, the cost of control is an appropriate basis for distinguishing among sources so long as it is not the sole basis for distinction.

The court’s analysis in Sierra Club is relevant to an analysis of the authority granted to EPA through CAA section 112. Section 112 employs the same language as Section 111 in defining when EPA may promulgate distinct emission standards for sources within a category or subcategory. The Supreme Court consistently has held that "when administrative and judicial interpretations have settled the meaning of an existing statutory provision, repetition of the same language in a new statute indicates, as a general matter, the intent to incorporate its administrative and judicial interpretations as well." Therefore, section 112, which adopted section 111’s terms almost ten years after the D.C. Circuit issued the Sierra Club decision, must be understood to carry the settled meaning given to those terms by that decision.

EPA’s past practice has been consistent with this interpretation of the Act. The Agency has subcategorized sources in numerous industrial categories. From this experience, it is possible to distill several principles that have guided the Agency’s decision making with regard to creation of subcategories. First, EPA has determined that subcategorization is appropriate where sources use different processes, and those processes result in different types or concentrations of uncontrolled HAPs. Here, for example, the suite of pollutants emitted by solid-fueled boilers differs from that emitted by liquid-fueled boilers, which in turn differs from that emitted by gas-fueled boilers. For example, the types of metals emitted by solid-fueled boilers differ from the types of metals emitted by liquid-fueled boilers, and gas-fueled boilers typically emit little metals, but may emit more organic HAPs. [See 68 Fed. Reg. at 1670 (January 13, 2003).] Thus, subcategorization based on fuel type is appropriate because the different types of boilers emit different types of HAPs.

The Agency also has subcategorized sources based on size, where size differences affect the performance of control technologies, such as where more frequent start up and shut down makes it more difficult for smaller sources to maintain the same level of control as larger sources. That is also the case here. There are fundamental differences in the design of small boilers, as compared to large boilers. Moreover, smaller units often are used in swing load mode, whereas larger units more typically are baseloaded. These smaller boilers have more frequent start ups and shut downs that impact the performance of control technology, and hence the achievability of the standard. Thus, subcategorization of boilers based on size – or infrequent utilization – also is consistent with EPA’s past precedent and is appropriate because of the impact of these factors on the ability of these sources to maintain the same level of control as larger sources.

Furthermore, the Agency has subcategorized sources where differences among sources affect the applicability of control technology. For example, EPA created subcategories in the 1999 polyether polyols production MACT standard, finding that "[s]ubcategorization was necessary due to the distinctively different nature of the epoxide and THF processes and its effect on the applicability of controls." [64 Fed. Reg. 29421 (June 1, 1999).] Similarly, in the 1998 flexible polyurethane foam production MACT standard, EPA found that "[s]ubcategorization was necessary to reflect major variations in production methods, and/or HAP emissions that affect the applicability of controls."[61 Fed. Reg. 68407 (December 27, 1996).]
Based on similar rationales, EPA created subcategories in the Group I polymers and resins NESHAP and the primary aluminum production NESHAP, and proposed to create subcategories in the polyurethane foam production NESHAP. [See, e.g., 40 C.F.R. Part 63, Subpart III (Flexible Polyurethane Foam Production), 40 C.F.R. Part 63, Subpart LL (Primary Aluminum Reduction Plants), and 40 C.F.R. Part 63, Subpart U (Group I Polymers and Resins).] Here, for example, fabric filters may be an appropriate control technology to capture metals from coal-fired boilers, but are not appropriate for use on oil-fired boilers because the soot blinds the bags of the fabric filter, and is also a fire hazard. Thus, subcategorization based on fuel type is appropriate because the type of fuel affects the applicability of control technology.

In sum, the use of subcategorization in this rule is amply supported by the language of the statute, the legislative history, applicable case law, and the Agency's own past practices. With these principles in mind, we believe that further subcategorization is warranted.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Comment Excerpt Number: 81

Comment: EPA needs to establish a subcategory for "limited use" units. While the prior Boiler MACT rule treated units with average capacity factors of 10% or less separately, the proposed rule does not continue that approach.

Instead, EPA presumes that limited use units are just like those operated full-time which burn a similar fuel. Limited use sources operate intermittently and for shorter periods of time (e.g., small package boilers that are only used during plant outages, a backup boiler that runs when other units are being fixed, a peaking unit used to supplement electric generation during particularly hot summer days, a process heater that operates for a few hours at a time to warm up a heat transfer fluid for use in a chemical process, or a process heater that only operates intermittently in order to maintain the temperature of a process fluid in the desired range).

Compared to most boilers and process heaters, these units spend a far greater percentage of their time starting up and shutting down. As a result, their emissions profiles differ from sources which operate in efficient steady-state manners. For example, they are likely to experience higher CO levels as the boiler or process heater heats up due to incomplete combustion. Similarly, many pollution control technologies are either difficult to use or ineffective during startup and shutdown periods and would be cost prohibitive to install and use for only short periods of time during a year. These are just the sort of "class" and "type" distinctions which merit consideration for subcategorization under section 112(d)(2).

Because limited use boilers and process heaters do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers and process heaters can vary significantly from those of a similar boiler or process heater operating in a steady state. "Combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit’s load (steam production) decreases."[75 Fed. Reg. 32023.]

Given their short run times, there are also technological limitations on how effectively emissions from these units can be controlled, particularly for organic HAP emissions. EPA indicated in the response to comments on the original Boiler MACT rule that it could not identify any control technologies that would reduce organic HAP emissions for limited use boilers, and thus could not identify a technology or method to reduce organic HAP emissions. [See Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP EPA-HQ-OAR-2002-0058-0649.] Finally, since "limited use boilers, when called upon to operate, must respond without failure and without lengthy periods of startup," [National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. 55218, 55232 (September 13, 2004).] a significantly larger percentage of their annual operation will be devoted to maintenance and readiness testing than other commercial, industrial, or institutional boilers. These differences noted in the 2004 boiler rule remain valid today and justify the creation of a subcategory for limited use boilers and process heaters.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 82

Comment: In March of this year, EPA established a limited use subcategory in the rule promulgating national emission standards for existing compression-ignition reciprocating internal combustion engines ("CI RICE") with a site rating of less than or equal to 500 brake horsepower.[See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. 9648 (March 3, 2010) (RICE rule).]

In the rule, EPA recognized that stationary existing CI RICE should be divided into non-emergency and emergency categories "in order to capture the unique differences between these types of engines." [Id. at 9650.] Like the limited use boilers in this rule and EPA’s 2004 boiler rule, EPA recognized that the emergency CI RICE are required to operate infrequently and for relatively short periods of time and must be kept in working order during prolonged periods of time when they are not operating.

As justification for its emergency unit subcategorization EPA cited an earlier memorandum titled ‘subcategorization and MACT Floor Determination for Stationary Reciprocating Internal Combustion Engines ?500 HP at Major Sources", Docket No. EPA-HQ-OAR-2008-0708-0006 (January 21, 2009). [Id. at 9705.] This memorandum, in turn, incorporated by reference the rationale found in the memorandum ‘subcategorization of Stationary Reciprocating Internal Combustion Engines ?500 HP", Docket No. EPA-HQ-OAR-2005-0030-0012 (May 15, 2006), which enumerated four reasons for creating a subcategory for emergency CI RICE:

Emergency use units are used when electric power from the local utility is interrupted or becomes unreliable. The duration of the power outages is entirely beyond the control of the source, and, when they do occur (except in the case of a major catastrophe) they rarely last more than a few hours, often only a few minutes.

Emissions from these units are expected to be low on an annual basis; emissions occur only during emergency situations or for a very short time to perform maintenance checks and operator training. State and local regulators generally have not required emission controls for emergency power/limited use units.

Add-on catalytic control devices that are most applicable to reduce HAP from stationary RICE would be less effective on an annual basis for emergency use units, since emergency use units generally operate for brief periods. Therefore, a greater percentage of the emergency use units" operation, as compared to operation of peaking or baseload engines, will occur during catalyst warm-up, when the catalyst’s effectiveness will be lower.

Emergency use units operate for very few hours per year. A survey conducted by the California Air Resources Board indicated that emergency engines are operated about 30 hours per year. Also, the National Fire Protection Association requires 30 minutes per week (27 hours per year) to maintain and test emergency engines. The recently finalized Airborne Toxic Control Measure in California allows districts to approve up to 100 hours per year for maintenance and testing of emergency engines. [Id. at 5-6.] [While these criteria focus on an "emergency use" subcategory, it is important to note that the limited duration of the use, not the purpose for using the RICE is the key issue. For example, the same rule also creates a subcategory for "black start" engines (engines used to start a turbine generator), which operate during both "emergency and high demand days." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. 55218; Rice Rule, 75 Fed. Reg. at 9662.]

These same criteria justify the establishment of a limited use boiler and process heater subcategory. First, limited use boilers are put into service only during maintenance outages, unexpected failures of the main boiler, or "when electric power from the local utility is interrupted or becomes unreliable" and some of these events are "entirely beyond the control of the source. [Id. at 5.] Second, because of their limited use during the year, "[e]missions from these units are expected to be low on an annual basis." [Id.] Third, for this same reason, a greater percentage of a limited use boiler or process heater's annual operations will be during startup and shutdown, when emissions controls such as a CO catalyst are less effective. [See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32023.] Finally, like emergency CI RICE, limited use boilers and process heaters operate for only a small portion of the year, typically "10 percent of the year or less."[69 Fed. Reg. at 55232 (September 13, 2004).]

Like emergency and black start CI RICE, limited use units should be placed into a subcategory that recognizes the unique challenges that would be faced monitoring and controlling emissions from these units.

In addition to the unique operating characteristics of limited use boilers, there are practical reasons for creating a limited use subcategory. As noted by Judge Williams in Sierra Club v. EPA, 'section 112(d)(1) authorizes the Administrator to "distinguish among classes, types, and sizes of sources within a category or subcategory" . . . . [O]ne legitimate basis for creating additional subcategories must be the interest of keeping the relation between "achieved" and

"achievable" in accord with common sense and the reasonable meaning of the statute. Sierra Club v. EPA, 479 F.3d 875, 884-85 (D.C. Cir. 2007) (Williams, J., concurring). If EPA fails to establish a subcategory for limited use boilers, these infrequently operated units will be force to comply with the emission limits set by completely dissimilar units, i.e., units that operate on a continuous basis. This is contrary to the language and intent of section 112.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment Excerpt Number: 83

Comment: Combustion units operate most efficiently when operated at or near their design capacity. It is well known that combustion efficiency tends to decrease as the unit's load (steam production) decreases. Limited use units, by their nature, will therefore be operating for a significantly greater percentage of their time during periods of inefficient operation.

While EPA has already attempted to address periods of unavoidable inefficient operation in the current floor analysis by addressing the reduced efficiency of load-following units through allowances for variability, [See MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 9-10 (April 2010).]this problem is amplified for limited use boilers, which EPA did not address in its MACT floor analysis, due to EPA's decision to include periods of startup and shutdown in determining compliance with MACT. EPA justifies the inclusion of periods of startup and shutdown by proposing standards that are daily or monthly averages. EPA states:

Continuous emission monitoring data obtained from best performing units, and used in establishing the standards, include periods of startup and shutdown. Boilers, especially solid fuel-fired boilers, do not normally startup and shutdown more the [sic] once per day. Thus, we are not establishing a separate emission standard for these periods because

startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards. [Id. at 32013.], [101 Id.]

Moreover, EPA found that "[p]eriods of startup, normal operations, and shutdown are all predictable and routine aspects of a source’s operation."101 While ACC presents comments relative to the inadequacy of the averaging periods relative to startup and shutdown periods elsewhere in these comments, neither of these findings reasonably applies to limited use units. EPA should not require limited use boilers to comply with standards set by best performing units that operate continuously.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: Section 112(h) of the CAA allows EPA to promulgate a design, equipment, work practice, or operational standard, or combination thereof, if it is not feasible to prescribe or enforce an emission standard and this authority has been affirmed in the D.C. Circuit.103 [Sierra Club v. EPA, 479 F. 3d 875, 884 (D.C. Cir. 2007).] Given the limited and sporadic operation of emergency and backup boilers, as well as the technical infeasibility of imposing emission limitations on these units, EPA should establish work practices standard in lieu of emission limits for limited use units.

EPA also used its section 112(h) authority in the RICE rule to set work practices, including regularly scheduled maintenance and the cataloging of hours of operation, for emergency use engines. See RICE rule at 9655-56. As stated by EPA, "EPA believes that work practices are appropriate and justified for this group of stationary engines because the application of measurement methodology is not practicable due to technological and economic limitations."[Rice Rule, 75 Fed. Reg. at 9556.]

As further stated by EPA:

[U]sing these procedures would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.[Id. at 9661.]

Similarly, as stated in the memorandum entitled "Existing Stationary Non-Emergency CI RICE Less Than 100 HP and Existing Stationary Emergency CI RICE Located at Major Sources and GACT for Existing Stationary CI RICE Located at Area Sources" (February 15, 2010) cited in EPA's final rule:

For existing stationary CI emergency engines located at major sources, EPA determined it is not feasible to prescribe or enforce an emission standard because the application of measurement methodology to this class of engine is impracticable due to the technological and economic limitations. Emergency engines typically only operate during emergencies or during periods of routine testing and maintenance. EPA determined that application of the emissions measurement methodologies during either of these periods is not practicable. It is impracticable to test emissions from stationary CI emergency engines during periods of routine testing and maintenance using the test procedures specified in the rule because it would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ. [Memorandum from Bradley Nelson and Tanya Parise, EC/R Incorporated to Melanie King, USEPA MACT Floor Determination for Existing Stationary Non-Emergency CI RICE Less Than 100 HP and Existing Stationary Emergency CI RICE Located at Major Sources and GACT for Existing Stationary CI RICE Located at Area Sources, February 15, 2010, Document ID: EPA-HQ-OAR-2008-0708-0327.]

EPA also excluded black start units from emission regulations in the RICE rule. While these units operate whenever a turbine generator starts, and therefore are not limited to emergency operations, EPA nonetheless recognized the importance of exempting these units from numeric standards, finding that "the short time of operation for these engines (10–15 minutes per start) makes application of measurement methodology for these engines using the required procedures, which require continuous hours of operation, impracticable. Requiring numerical emission standards for these engines would actually require substantially longer operation than would occur normally in use, leading to greater emissions and greater costs."[Id. at 9662.]

As EPA found, "[t]he majority of stationary CI engines are used for emergency purposes. EPA has estimated that 80 percent of stationary CI engines are emergency engines and EPA has taken steps in the final rule to reduce the burden on owners and operators of these engines." [Id. at 9658.] Rather, the basis for promulgating work practices in lieu of emission standards is the infeasibility of prescribing or enforcing an emission standard.109[See 42 U.S.C. section 7412(h).]

Emergency, startup, and backup boilers and process heaters, like emergency and black start CI RICE, are operated for only short periods of time and cannot feasibly be tested pursuant to EPA standards. Work practices should therefore also serve in lieu of emission monitoring and control technology for emergency, startup and backup boilers. For example, under section 63.7545(d) of this proposed rule , a Notification of Intent must be submitted at least 30 days before any performance test. As a result, even if a limited use boiler were operated for an entire month after an unplanned start, there would be no time to conduct the necessary performance tests. In addition, most test methods require steady state conditions that may not be achieved during limited use operations and, once a steady state has been reached, would require the boiler to continue operating at steady state for enough time to conduct the three 4-hour test runs required by the proposed rule for most compliance tests. [See proposed section 63.7520(d). Even during regular operation, a limited use boiler would still need to operate for at least 12 hours in steady state condition in order to accommodate the variability attendant in these performance tests. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32033 (stating that EPA selected a 12 hour averaging period for demonstrating continuous compliance "to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits").] Some limited use process heaters will not be able to be operated for the amount of time necessary to accommodate an emissions test if they serve a distinct role of heating a process fluid, as the process fluid cannot be overheated.

Similarly, EPA is proposing in this rule that boilers and process heaters with heat input capacities greater or equal to 100 MMBtu/hr demonstrate that average CO emissions, on a 30-day rolling average, are at or below the proposed CO limit. This averaging period is essential to accommodating expected data variability, including SSM events.[See, e.g. National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. at 5521. See also Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 102 (rejecting a 24-hour averaging period because a 30-day rolling average "accounts for the variability in fuel characteristics (e.g., moisture, Btu content, mixture) that occur for solid fuel-fired boilers and process heaters").] Without the ability to test for 30 continuous days or thereabouts, a limited use unit cannot be expected to meet the same emission limits due to their reduced ability to accommodate data variability, and operators cannot adequately determine compliance with numeric emission limits.

The result would be a marked inability to practically measure emissions without operating these units for significant periods of time for the sole purpose of conducting emissions testing. As with the recently regulated emergency CI RICE, this would result in a new increase in emissions through the very effort to control emissions from these units. [RICE Rule, 75 Fed. Reg. at 9655-56.] Work practices are therefore the most feasible control for limited use boilers and process heaters and should be adopted in the final rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: The electric utility industry utilizes boilers that burn either natural gas or distillate oil and may be subject to EPA's proposed Subpart DDDDD. These units are called auxiliary boilers ("Aux Boilers") and typically are operated only a limit number of hours (e.g., on the order of 1,000) in a calendar year. An Aux Boiler is used to generate the steam that is necessary to bring a main electric generating unit (EGU) on line. Since many electric utility boilers use various stream-driven equipment (e.g., feed water pumps, induced draft fans, etc.), the units cannot be brought online without an independent supply of steam. If a power plant has only one EGU, then it almost certainly must use its Aux Boiler to bring the main unit online. Power plants that have multiple EGUs may also have Aux Boilers, but those Aux Boilers are often not needed because of inter-steam piping among the EGUs. That is, an EGU can be brought online utilizing the steam generated in another EGU, which is already online. Such Aux Boilers tend to have very low capacity factors.

As stated above, the electric utility industry burns either natural gas or distillate oil in their Aux Boilers. Natural gas is the fuel of choice, but all power plants do not have access to pipeline natural gas service. Therefore, these plants must rely on distillate oil. For units with limited service, like utility Aux Boilers, EPA's proposed work practice standards for units that burn natural gas may be more than is needed, but it is neither cost prohibitive nor technical infeasible. On the other hand, the proposed compliance provisions appear unreasonable for limited use boilers that burn distillate oi1.24 First, Aux Boilers are not going to and should not need to employ control technology to meet the emission limits when burning a clean fuel like ultra-low sulfur diesel (ULSD). Second, because the demand for an Aux Boiler to operate is almost impossible to forecast, it is almost a certainty that each Aux Boiler subject to proposed Subpart DDDDD would have to be operated some time during each year for the sole purpose of emission testing. Such an outcome would constitute very poor public policy because: (1) unnecessary air pollutants would be generated; (2) unnecessary carbon emissions would occur; and (3) a valuable and not unlimited resource (ULSD diesel) would be wasted. Since there is no control technology to verify the performance of, a work practice (boiler tune-up) would be a reasonable approach for limited-use boilers that burn clean fuel.

Comment: EPA should establish a subcategory specific to bagasse boilers, wholly separate from all other biomass boilers. A separate subcategory is warranted because bagasse boilers are different in kind from other biomass boilers based on fuel type and boiler design—the two criteria that EPA has offered to explain its current subcategorizations. See 75 Fed. Reg. 32,017; see also Sierra Club v. EPA, 479 F.3d 875, 885 (D.C. Cir. 2007) (Williams, J., concurring) (EPA's "authority to generate subcategories" is only "limited by the usual ideas of reasonableness").

EPA notes the following in the proposed rule: "EPA has attempted to identify subcategories that provide the most reasonable basis for grouping and estimating the performance of generally similar units using the available data. We believe that the subcategories we selected are appropriate. EPA requests comments on whether additional or different subcategories should be considered. Comments should include detailed information regarding why a new or different subcategory is appropriate (based on the available data or adequate data submitted with the comment), how EPA should define any additional/different subcategories, how EPA should account for varied or changing fuel mixtures, and how EPA should use the available data to determine the MACT floor for any new or different categories." See 75 Fed. Reg. 32,017.

The establishment of emission limits for the broad "biomass" subcategory does not accurately reflect the wide variation of emissions anticipated for the primary type of biomass fuel combusted at the Clewiston facility (bagasse). Similar source has previously been defined by EPA as: "a stationary source or process that has comparable emissions and is structurally similar in design and capacity to a constructed or reconstructed major source such that the source could be controlled using the same control technology." See 40 CFR §63.41.

There are four factors to consider when defining similar sources (or subcategories): 1) comparable emissions, 2) structurally similar in design, 3) structurally similar in size, and 4) capable of control using the same control technology.

The separation into subcategories by the broad classification of "biomass" fuel is complicated by the multi-fuel nature of many biomass boilers. FSI has submitted extensive comments on this topic. As those submissions make clear, bagasse has important differences from other biomass fuels. Most notably, bagasse contains approximately 50% moisture and has very low density (compared to other dry biomass such as hog fuel, which EPA also grouped into "biomass" fuel).

The difference in combustion of wet and dry fuel is significant. Wet fuels such as bagasse require more heat to evaporate the inherent moisture, which directly impacts the emissions of CO and PM (and the HAP for which they are surrogates). Thus, the combustion of bagasse does not result in “comparable emissions” to other forms of biomass, and bagasse has failed the first factor of being defined a similar source with other biomass. FSI’s submissions also show that bagasse boilers are designed differently than other biomass boilers. Bagasse boilers also are fully integrated with the sugar mill in the continuous milling process. These differences, as well as several others that FSI’s comments cover in depth, call for separate regulatory treatment of bagasse boilers. U.S. Sugar adopts FSI’s comments and refers EPA to FSI’s submissions.

Response: See response to comment EPA-HQ-OAR-2002-0058-1841.1, excerpt 2 for bagasse boiler subcategory.

Comment: Industrial boilers that have specialized uses and are therefore operated infrequently should be listed in a separate subcategory. Such auxiliary boilers are often operated primarily during plant startups, and as such emit very low levels of HAPs. These boilers should be categorized as those with a 10 percent capacity factor for the maximum hourly heat input, and should be subject to a work practice standard under Section 112(h) of the CAA.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Comment: EPA should establish a subcategory for "limited use" units due to their significant differences from steady-state units
In the preamble discussion, it appears that the EPA intended to provide that a natural gas-fired boiler that receives less than 10% of the annual heat-input from liquid fuels would be considered a natural gas-fired boiler for purposes of regulation under the MACT rule, and thus only subject to the annual tune-up requirements. However, the proposed restricts the use of liquid fuels to periods of testing or supply curtailment.

This is problematic and inappropriate because “plant-side” equipment may require the use of liquid fuels to provide for maintenance of natural gas systems during periods that do not constitute emergencies as narrowly defined in the proposed rule.

Response: Please refer to the preamble for discussion of the limited use subcategory.

See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment: A Limited Use Subcategory is Supported by EPA's Recent Similar Treatment of Emergency and Black Start Compression Ignition Engines. In March of this year, EPA provided a similar subcategory in its final rule promulgating national emission standards for existing compression-ignition reciprocating internal combustion engines ("CI RICE") with a site rating of less than or equal to 500 brake horsepower. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 FR 9648 (March 3, 2010).

In that Rule, EPA recognized that stationary existing CI RICE should be divided into non-emergency and emergency categories "in order to capture the unique differences between these types of engines." Id. at 9650. Like the limited use boilers described in EPA's September 13, 2004 rule, EPA recognized that these emergency CI RICE are required to operate infrequently and for relatively short periods of time and must be kept in working order during prolonged periods of time when they are not operating.

EPA cited as justification for its emergency unit subcategorization an earlier memorandum titled Subcategorization and MACT Floor Determination for Stationary Reciprocating Internal Combustion Engines ?500 HP at Major Sources, Docket No. EPA-HQ-OAR-2008-0708-0006 (January 21, 2009). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 74 Fed.Reg. 9,698, 9,705 (March 5, 2009). This memorandum, in turn, incorporated by reference the rationale found in the memorandum Subcategorization of Stationary Reciprocating Internal Combustion Engines ?500 HP, Docket No. EPA-HQ-OAR-2005-0030-0012 (May 15, 2006), which enumerated four reasons for creating a subcategory for emergency CI RICE: "Emergency use units are used when electric power from the local utility is interrupted or becomes unreliable. The duration of the power outages is entirely beyond the control of the source, and, when they do occur (except in the case of a major catastrophe) they rarely last more than a few hours, often only a few minutes".

Emissions from these units are expected to be low on an annual basis; emissions occur only during emergency situations or for a very short time to perform maintenance checks and operator training. State and local regulators generally have not required emission controls for emergency power/limited use units.

Add-on catalytic control devices that are most applicable to reduce HAP from stationary RICE would be less effective on an annual basis for emergency use units, since emergency use units generally operate for brief periods. Therefore, a greater percentage of the emergency use units' operation, as compared to operation of peaking or baseload engines, occurs during catalyst warm-up, when the catalyst's effectiveness is lower.

Emergency use units operate for very few hours per year. A survey conducted by the California Air Resources Board indicated that emergency engines are operated about 30 hours per year. Also, the National Fire Protection Association requires 30 minutes per week (27 hours per year) to maintain and test emergency engines. The recently finalized Airborne Toxic Control Measure in California allows districts to approve up to 100 hours per year for maintenance and testing of emergency engines. Id. at 5-6. [While these criteria focus on an "emergency use" subcategory, it is important to note that the limited duration of the use, not the purpose for using the RICE is the key issue. For example, the same rule also creates a subcategory for "black start" engines (engines used to start a turbine generator), which operate during both "emergency and high demand days." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed.Reg. 55218 at 9662.]

These same criteria justify the establishment of a limited use boiler MACT subcategory. First, limited use boilers, whether used as backup or emergency use boilers, are put into service only during unexpected failures of the main boiler or "when electric power from the local utility is interrupted or becomes unreliable" both of which are events "entirely beyond the control of the source." Id. at 5. Second, because of their limited use during the year, "[e]missions from these units are expected to be low on an annual basis." Id. Third, for this same reason, a greater percentage of a limited use boiler's annual operations will be during startup and shutdown, when emissions controls are less effective. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed.Reg. at 32,023. Finally, like emergency CI RICE, limited use boilers operate for only a small portion of the year, typically "10 percent of the year or less." National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed.Reg. at 55232.

For example, the City of Painesville operates one municipal utility boiler that only operates when the primary unit goes down or during periods of high demand when additional power generation is necessary to maintain the reliability of power to the City and basic services, such as police stations, fire departments, and hospitals. Between 2004 and 2008, this boiler operated for an average 583.5 hours per year, operating only during 15 months of that five-year span and for periods ranging from as little as 15.25 hours in a month to as much as 588.25 hours. This boiler would clearly meet the definition of a limited use boiler. Even assuming operation at maximum capacity throughout its entire operation, it would have emitted less than 1/10 its potential emissions but would have been in periods of startup or shutdown 15 times longer than a continuously operated boiler.

Like emergency and black start CI RICE, emergency and backup boilers like Painesville's Boiler #3 should be placed into a subcategory that recognizes the unique challenges that would be faced monitoring and controlling emissions from these units.

Commenter Affiliation: Constellation Energy
Document Control Number: EPA-HQ-OAR-2002-0058-3164
Comment Excerpt Number: 1

Comment: Constellation supports sub-categorization. Standards synthesized from different units may be impossible to meet in practice by any one unit. Boilers with different designs, such as bubbling bed or circulating fluidized bed (CFB), and associated varying control technologies, such as multi-done and Electrostatic precipitator (ESP), emit varying quantities of NOx, CO, PM, and VOCs. They also have varying fuel sources with fluctuating quality. Therefore, selecting the lowest emission limit per constituent from various different boiler units may not be an accurate reflection of any individual operating boiler. It is unreasonable to require an individual unit to meet all of the lowest limits compiled from multiple boilers of different design technologies

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA's authority to create subcategories.

Document Control Number: EPA-HQ-OAR-2002-0058-2845.1
Comment Excerpt Number: 35

Comment: The Clean Air Act provides EPA with discretion to subcategorize based on size,type and class of source.

CAA 112(c)(1) instructs EPA to establish "categories and subcategories" of sources for regulation under Section 112. CAA 112(d)(1) then further provides that EPA "may distinguish among classes, types and sizes of sources within a category or subcategory" when establishing MACT standards. These provisions vest EPA with the clear authority to group like units for purposes of establishing emissions limitations. EPA's subcategorization decisions, however, must turn on legitimate "class" "type" or size" distinctions as required by 112(d).

The legislative history explains what Congress meant when it authorized EPA to distinguish among sources by “class” “type” or “size.” The relevant Senate Report indicates that EPA should:

[T]ake into account factors such as industrial or commercial category, facility size, type of process and other characteristics of sources which are likely to affect the feasibility and effectiveness of air pollution control technology. Cost and feasibility are factors which may be considered by the Administrator when establishing an emission limitation for a category under Section 112 . . . where a group of sources may share the characteristics of other sources in the category, the Administrator may establish subcategories for such sources.

S. REP. NO. 228, 101st Cong., 1st Sess. 166 (emphasis added).

That language has two key implications. First, it confirms that Congress’ use of the broad concepts of “class” “type” or “size” was meant to allow subcategorization based on (and require consideration of) a broad array of factors. That is particularly true given Congress’ open-ended statement that EPA should consider “other characteristics of sources” when grouping them for purposes of establishing emissions limits. Second, this statement confirms that, while cost issues alone may not be sufficient to require subcategorization, costs are relevant to subcategorization decisions. See also, Id. (indicating that subcategorization “wholly on economic grounds” is inappropriate) (emphasis added). By clarifying that individual facilities may not be granted categorical waivers “based on assertions of extraordinary economic effect,” id., the Senate Report confirms that the threat of severe economic consequences on a subgroup sharing other common attributes supports subcategorization.11

Thus, 112(d)(2) authorizes (and requires) EPA to consider differences in “commercial category, facility size, type of process and other characteristics” that may affect: (1) feasibility of control technology, (2) effectiveness of control technology, and (3) costs of control. Where those factors are present, subcategorization is warranted.

Response: See response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 145 for EPA’s authority to create subcategories.

Commenter Name: Wayne Brandt
Commenter Affiliation: Minnesota Forest Industries
Document Control Number: EPA-HQ-OAR-2002-0058-3220
Comment Excerpt Number: 12

Comment: Many facilities, including Minnesota forest products industries, have backup boilers that operate only when the primary units are down due to malfunction or maintenance. Typically, back-up boilers operate at 10% or less of annual capacity. The cost to upgrade a small package boiler is estimated by AF&PA to be $10 million. It is not cost-effective to add-on expensive pollution control equipment for sources that operate at 10% or less annually. In addition, testing protocols would require operation when the boilers are not needed. EPA should include a subcategory for limited use boilers, or a de minimis applicability threshold for small or limited use units.

Response: Please refer to the preamble for discussion of the limited use subcategory.

Subcategories: Coal

Commenter Name: John C. Hendricks
Commenter Affiliation: American Electric Power
Document Control Number: EPA-HQ-OAR-2002-0058-2703.1
Comment Excerpt Number: 2

Comment: EPA Should Consider Additional Subcategories for Industrial Boilers. AEP encourages EPA to more fully use its discretion in providing for sub-categorization in determining the MACT limits. In particular, AEP would like the EPA to recognize the variability in "coal" and provide differing MACT limits for bituminous, sub-bituminous, and lignite, and recognized, as the EPA has done in the past, that there are substantial differences in the coal ranks. Boilers are designed for a specific type of coal and are unable to change fuels. The proposed limits should account more fully for this variability by adding additional subcategories. While AEP does not operate any coal fired Industrial Boilers, AEP has concerns with this approach in anticipation of the upcoming Electric Generating Unit (EGU) MACT.

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 86

Comment: While EPA did consider a wider range of units for variability in coal, variability in coal quality occurs within individual seams and within one unit's supply, which may come from different sources, and EPA's testing did not account for this difference in fuel quality. If considering variability in fuel quality across different types of fuel within a single subcategory is too difficult, that may be an indication that EPA should subcategorize based on fuel types down to specific fuels and materials. Additional subcategorizing within fuel groups may be particularly warranted here, given that EPA has (rightfully) ruled out fuel switching, which would in any event be impossible for many regulated sources. Section 112(d)(1) authorizes the Administrator to "distinguish among classes, types and sizes of sources within a category or subcategory," and the Agency's discretion in identifying these subcategories quite broad, perhaps simply "limited by the usual ideas of reasonableness." See Brick MACT, 479 F.3d at 885 (Williams, J., concurring).

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 24

Comment: Within the Boiler MACT “coal-fired” category, EPA proposes separate subcategories for stoker, fluidized bed and pulverized coal designs. However, we know of no reason why well-controlled units of these designs should differ significantly in levels of HAP emissions. EPA’s subsequent MACT floor analysis leads to calculated MACT floor levels that are often identical and are within the variability expected of such measurements, thus documenting the lack of a basis for a separate subcategory.

Response: See response to comment EPA-HQ-OAR-2002-0058-2880.1, excerpt 89.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 158

Comment: Subcategories are needed for new source coal boiler standards. The proposed new source standards are unrealistic and, if left unchanged, could seriously endanger the nation’s long-term prospects for growth in the manufacturing sector. Reports we hear from suppliers of boilers and air pollution control systems are that they will not be able to supply commercial guarantees to meet the proposed standards. Additional subcategories which focus on the regional fuel supplies (Powder River Basin, Illinois Basin, Central Appalachian, etc) are needed to allow future boilers to be installed across the nation. For example, the top performer used to set the HCl standard for new coal-fired boilers is a boiler which burns sub-bituminous coal, which inherently has much lower chlorine content than eastern coals. A facility on the east coast should not have to meet standards that can be met only by burning a fuel only obtained from hundreds if not thousands of miles away. EPA should not set new source standards that prohibit certain coal types. The US Geological Survey has a coal quality database that can be examined for coal pollutant content information. http://energy.er.usgs.gov/products/databases/CoalQual/index.htm

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

EPA disagrees that additional subcategories are needed for new sources to further incorporate fuel quality. Fuel variability was incorporated into the new source floor values when data was available for the single best performing unit.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 6

Comment: EPA should further subcategorize fuel types to include subcategories based on coal rank.
As explained above, Luminant also has an interest in the methodology behind the proposed rule as it relates to EPA's process for developing MACT standards and how that process might impact the EGU MACT standards currently under development. Again, Luminant supports EPA's subcategorization of units based on fuel type and combustion processes. For the same reasons EPA has subcategorized units based on fuel burned, EPA should create subcategories based on coal rank. Units should be further subcategorized by the geographic location from which the coal is mined. EPA has the authority to subcategorize based on coal rank and should exercise that authority, given "that there are sufficient differences in the design and operation of utility boilers utilizing the different coal ranks to justify subcategorization by major coal rank." See 70 Fed. Reg. 28,606, 28,613 (May 18, 2005) (original NESHAP for EGUs).

For example, Texas lignite features relatively high ash content that can be highly alkaline. Texas lignite also has lower levels of chloride and higher levels of mercury when compared with other coal ranks. Furthermore, the mercury content of Texas lignite can vary greatly not only from mine to mine, but from seam to seam. Lignite is a very volatile fuel and has relatively low volatile organic compound emissions but may have higher carbon monoxide emissions due to boiler design and/or low NOX controls. Thus, while units designed to burn Texas lignite may be able to meet acid gas, volatile organic HAP, and dioxin floors, they may have great difficulty in meeting overly stringent mercury and non-mercury metals floors. If EPA proceeds with setting floors for individual HAPs or HAPs categories, then subcategories need to be established for individual coal ranks and, in some cases, mining locations.

As the D.C. Circuit has explained, "[i]f factors other than MACT technology do indeed influence a source's performance, it is not sufficient that EPA considered sources using only . . . MACT controls . . . ." Sierra Club v. EPA, 479 F.3d 875, 882 (D.C. Cir. 2007) (internal citations omitted). Thus, EPA must consider non-technology factors, i.e., fuel content, that affect emission levels when developing floor limits. See id. at 883. Given the significantly different characteristics of lignite and other coal ranks, EPA should create additional subcategories for units burning each coal rank.

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Commenter Name: William A. Moore
Commenter Affiliation: Luminant
Document Control Number: EPA-HQ-OAR-2002-0058-2780.1
Comment Excerpt Number: 10

Comment: EPA's appropriate policy choice in this regard – that fuel-switching is not an appropriate control technology – logically and necessarily supports adding a lignite subcategory. Without such a subcategory, if NESHAPs are established in whole or in part upon non-lignite fuel, a lignite-burning unit would have to switch fuels to another (distantly-mined, in lieu of locally-mined) type of coal.

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 11

Comment: The Clean Air Act allows the Administrator to distinguish among “classes, types, and sizes of sources” when developing standards under Section 112. Nowhere in Section 112 does it limit EPA to only basing subcategories to instances where the class, type, or size has an effect of emissions. However, in the proposed rule, EPA has indicated that the subcategories are warranted because “differences between given types of units can lead to corresponding differences in the nature of emissions and the technical feasibility of applying emission control techniques”. While Southern Company does not disagree with this statement, we do disagree that EPA must only subcategorize if the class, type, or size has an effect on emissions.

Southern Company agrees with EPA’s decision to set a large number of subcategories in the proposed IB MACT rule; however, the number of subcategories that EPA chose is not sufficient and should be expanded to distinguish between various coal ranks. Historical testing has shown that coal rank has a significant effect on mercury and HCl emissions. EPA should further subcategorize coal-fired boilers based on coal rank (bituminous, subbituminous, lignite, etc.).

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Comment: Support for subcategorization of boilers and process heaters

AECT commends EPA for considering differences in combustion technology by creating subcategories in the lB MACT proposed rule; however, EPA should have also created subcategories by coal rank. Historical testing has shown that coal rank has a significant effect on mercury and HC1 emissions. Failure to do so confounds the practical compliance ability of any facility due to the illogical approach of setting limits based on the performance of control technology in isolation of the facility as a source.

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Comment: EPA Should Identify More Subcategories of Coal-fueled and Specialized Industrial Boilers

Section 112(d)(1) of the Clean Air Act (CAA) states that, in promulgating regulations establishing emission standards for major sources, the "Administrator may distinguish among classes, types, and sizes of sources within a category or subcategory in establishing such standards." Section 112(c)(1) also states that, while "categories and subcategories listed under this subsection shall be consistent with the list of source categories established pursuant to Section 111 of this title," nothing in that statement "limits the Administrator's authority to establish subcategories under this section, as appropriate."

In coal-fueled industrial boiler units, testing has clearly indicated that coal rank has a significant effect on the emission levels of HCl and mercury. Low-rank coals such as lignite and sub-bituminous coals have higher moisture levels and lower carbon and energy levels, whereas high-rank coals such as bituminous and anthracite colas have lower moisture levels and higher carbon and energy levels. These qualities of the various types of coal have a direct effect on the resulting HCl and mercury emissions of the boilers that use them as feedstock. Therefore, pursuant to Section 112(d)(1), multiple subcategories should be created in the coal-fueled industrial boiler category based upon the particular type of coal combusted by the unit.

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Comment: EPA created subcategories for all pollutants based on fuel type, recognizing that "design, operating, and emissions infbrmation . .. indicates differences in unit design that distinguish di Iferent types of boilers." 75 Fed. Reg. at 32016-17. EPA determined that differences between units combusting coal, biomass, liquid fuel, natural/refinery gas, and process gas impacted emissions and warranted separate subcategories and emissions limits for each fuel type. Id. at 32017. For certain HAP, EPA expressly stated that emissions are -dependent upon the composition of the fuel." Id.

AMP agrees with EPA’s conclusion that fuel is an important factor affecting emissions; however, EPA’s subcategories do not go far enough in that they fail to account for significant differences in fuel composition within each proposed fuel subcategory. EPA should further subcategorize where distinct ranks of fuel exist. That is particularly important for the coal subcategories. Coal-fired units burn well-known ranks of coal, including bituminous, sub-bituminous, lignite, and anthracite. These distinct coal types have different chemical compositions that directly impact emissions of regulated pollutants. These differences may make it impossible for units burning a particular rank of coal to meet emission limits that are based on the combustion of different coal ranks.

For example, notable differences in mercury and chlorine content exist between the various coal ranks. Sub-bituminous coal has an average mercury content that is less than half of anthracite coal and significantly less than the other fuel ranks. See Comments from Domtar Industries, Inc. at 67 Tbl. 3 (Mar. 14, 2003) (EPA-HQ-OAR-2002-0058-0387) (citing Electric Power Research Institute, An Assessment of Mercury Emissions from U.S. Coal-Fired Power Plants (Sept. 2000)). Thus, basing emission limits on data from all units regardless of coal rank would result in floors set by units that happened to be combusting low-mercury coal during testing that is not universally usable. This leaves the rest of the source subcategory without a clear pathway to attain the MACT floor emission level particularly when control technology cannot reduce the uncontrolled emission rate sufficiently to meet the MACT floor emission limit. A similar problem exists regarding HCl limits. Bituminous coal contains more than three times the average chlorine of any of the other coal ranks. Id. These differences render general MACT floors based on all coal combustion unrepresentative and would make it exceptionally difficult (and perhaps impossible) for sources that burn coal ranks with higher mercury or chlorine content to achieve the resulting limits, even when operating the same controls used at best-performing sources. {Footnote: Consider HCI at the MACT emission limit of 0.02 lb/mmBtu after scrubber controls on a sub-bituminous coal-fired unit. Assuming HCI control efficiency at 99%, the uncontrolled rate is 2.0 lb/mmBtu. A comparable bituminous coal-fired unit would be expected to have three times the uncontrolled HCI emission rate, or 6.0 lb/mmBtu. Applying scrubber controls at 99% control efficiency would yield controlled emissions of .06 lb/mmBtu, which is three times higher than the MACT floor emission rate. Compliance is unachievable through control measures.]

Nor is coal switching a viable option since coal rank goes to the heart of unit design. Coal-fired boilers are specialized units that are designed to operate effectively burning a particular type of coal. Based on its unique expertise designing and adapting boilers, Babcock & Wilcox explains that "the deposition and erosion potential of the ash are the primary design considerations driving the overall size and arrangement" of coal-fired boilers. Steam, Its Generation and Use (Babcock & Wilcox) at 21-1. That is true because:

The effective utilization of fossil fuels for power generation depends to a great extent on the capability of the steam generating equipment to accommodate the inert residuals of combustion, commonly known as ash. The quantity and characteristics of the ash inherent to a particular fuel type are major concerns to both the designer and the operator of the equipment.

Id. Ash deposition and slag deposits cause numerous problems in boilers including reduced heat absorption, increased exit gas temperature (which causes additional slagging), fouling in convection banks, and dangerous slag buildups that can become dislodged and fall, causing failure of furnace tubes and other equipment damage.

To protect against these concerns, boilers are designed to accommodate the ash creation potential of the coal that will be used. Specifically, boilers that burn sub-bituminous or lignite coals must be designed with "ample clearance . . . between the burners and furnace walls as well as the furnace hopper and arch" which are "keyed to the slagging classification of the coal." Id. at 21-15. Boilers that burn higher ash coal are larger, with increased depth "to control slagging by reducing the input per plan area" and "side space dimensions" which "depend on the fouling classification of the coal" with higher ash coals requiring wider spacing. Id. at 21-16. Further, bank depths are established in part "as a function of fouling potential. . . . " Id. In other words, boilers must be designed larger to accommodate the higher ash content sub-bituminous and lignite coals that are mined primarily in the western United States.

These key differences preclude boilers designed to burn bituminous coal from simply switching to lower grades. For example, most units located in the Midwest are designed smaller to efficiently burn the high Btu, low ash bituminous coal that is locally available. Although bituminous coal has higher average mercury content than other types of coal, these units cannot simply turn to other, lower mercury, coal ranks to meet emission limits. Rather, their design and dimensions dictate that, to operate properly and avoid fouling, they must use higher-Btu bituminous coal. That renders these units technically incapable of meeting mercury levels that can be achieved by boilers that burn sub-bituminous and lignite coal with lower average mercury content.

This is precisely the situation that Congress intended, and the courts recognized, as ripe for subcategorization to bridge the gap between what is achieved and achievable within the MACT source category. The D.C. Circuit has also recognized the importance of achievability in reviewing MACT standards and has expressly confirmed that subcategorization is an important tool to help ensure that MACT standards are achievable in practice. Sierra Club, 375 U.S. App. D.C. at 238 ("[O]ne legitimate basis for creating additional subcategories must be the interest in keeping the relation between ‘achieved’ and ‘achievable’ in accord with common sense and the reasonable meaning of the statute."). Without subcategorization according to the different coal ranks, many units will find themselves unable to meet emission limits even with installation of MACT controls. As such, subcategorization by coal rank is necessary and warranted.

Response: The EPA disagrees with the commenters suggestion to further subcategorize solid fuel units based on the type of coal burned. The EPA recognizes the variation in emissions between different coal types, as well as difference within each coal type, and differences between coal and other solid fuels. However, the EPA also does not see any justification for any further subcategorization. Although there may be variation in the amount of pollutants emitted, the type of pollutants emitted will be similar between all solid fuel units (particulate matter, metallic

HAP, and inorganic HAP). As a result, similar control technologies may be used. The EPA also considers that variability has been incorporated into the MACT floor analysis because the emission limits developed for the MACT floor level of control incorporate boilers using various fuels, various combustor types, and variations of the same control device.

Commenter Affiliation: National Association of Manufacturers
Document Control Number: EPA-HQ-OAR-2002-0058-2845.1
Comment Excerpt Number: 31

Comment: While EPA did consider a wider range of units for variability in coal, variability in coal quality occurs within individual seams and within one unit's supply, which may come from different sources, and EPA's testing did not account for this difference in fuel quality. If considering variability in fuel quality across different types of fuel within a single subcategory is too difficult, that may be an indication that EPA should subcategorize based on fuel types down to specific fuels and materials. Additional subcategorizing within fuel groups may be particularly warranted here, given that EPA has (rightfully) ruled out fuel switching, which would in any event be impossible for many regulated sources. Section 112(d)(1) authorizes the Administrator to "distinguish among classes, types and sizes of sources within a category or subcategory," and the Agency's discretion in identifying these subcategories quite broad, perhaps simply "limited by the usual ideas of reasonableness." See Brick MACT, 479 F.3d at 885 (Williams, J., concurring).

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Comment: EPA proposes to establish strict MACT standards for coal-fueled boilers.Additionally, boilers and process heaters need only burn at least 10 percent coal on an annual average heat input basis to be classified in the coal category. EPA, however, did not propose MACT standards for owners or operators of boilers or process heaters which combust natural gas or refinery gas. Instead, EPA proposed a "work practice" standard that would be applied to those units. This work practice standard would require only that owners or operators of such boilers perform a tune-up and art energy assessment in order to comply with this rule.

According to EPA, these work practice requirements will reduce cumulative emissions from natural gas-fueled units by a meager 212.21 tons. In contrast, the emission limits applied to coal-fueled units will result in those units being forced to reduce their total tons per year of emissions by a cumulative 53,717.1 tons.

Response: See the preamble for discussion of how EPA selected work practice standards for gas 1 units.

Comment: Section 112(d)(1) of the CAA allows the Administrator to distinguish among "classes, types, and sizes of sources" in establishing MACT standards. This subcategorization language mirrors earlier language found in CAA § 111(b)(2).[In CAA § 112(c)(1), Congress provided that, to the extent practicable, the categories and subcategories under § 112 "shall be consistent with the list of source categories" under § 111.] In providing EPA discretion to create subcategories, § 112(d)(1) does not restrict subcategorization to cases where the "class", "type" or "size" factors affected HAP emissions. The provision merely requires EPA to establish regulations for each category or subcategory on the schedules set out in § 112. Indeed, EPA has not previously subcategorized under § 111 based solely on emission effects. For example, under § 111 EPA has subcategorized boilers on the basis of size (heat input) or the type of fuel burned (coal, oil or gas). These subcategorization decisions were based on feasibility and/or cost considerations, not on the level of emissions.

UARG commends EPA for creating a large number of subcategories in the proposed IB MACT rule. However, EPA should have created more subcategories. Historical testing has shown that coal rank has a significant effect on Hg and HCl emissions. Also, as discussed in section K below, a limited use subcategory should be created for industrial boilers that are operated infrequently because of their specialized nature and use.

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Comment: Subcategories. The coal subcategories should be broken down by fuel type i.e., anthracite, bituminous, and subbituminous. There are inherent differences in HAP content for these different coal types. As noted on page 32010, "the presence or absence of HAP in fuel materials must be accounted for in establishing floors * * *."

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 78

Comment: The Clean Air Act authority granted to EPA for proper subcategorization is applicable to fuel types among a fuel class. Specifically, coal types such as anthracite, bituminous, subbituminous, and lignite are well known to have different constituent levels and overall fuel properties. EPA has identified these differences in their NSPS regulations for steam generating units by setting limits for certain pollutants based on coal type. The properties of the different coal types can require differing furnace configuration, firing method, equipment design, and even emissions control equipment, since the coal properties affect the applicability and effectiveness of some emissions controls. When setting emission limits at or near the limits of detection, differences between fuel type become more important. This is especially notable relative to the mercury and chlorine contents generally seen in different coal types (i.e., subbituminous coal can have much lower Cl and Hg content than bituminous coal).

At a minimum, additional subcategories are needed for new source coal boiler standards. The proposed new source standards are unrealistic and, if left unchanged, could seriously endanger the nation's long-term prospects for growth in the manufacturing sector. Reports we hear from suppliers of boilers and air pollution control systems are that they will not be able to supply commercial guarantees to meet the proposed standards. Additional subcategories which focus on the regional fuel supplies (Powder River Basin, Illinois Basin, Central Appalachian, etc.) are needed to allow future boilers to be installed across the nation. For example, the top performer used to set the HCl standard for new coal-fired boilers is a boiler which burns sub-bituminous coal, which inherently has much lower chlorine content than eastern coals. A facility on the east coast should not have to meet standards that can be met only by burning a fuel only obtained from hundreds if not thousands of miles away. EPA should not set new source standards that prohibit certain coal types. The US Geological Survey has a coal quality database that can be examined for coal pollutant content information. [Available at http://energy.er.usgs.gov/products/databases/CoalQual/index.htm]

Response: See response to comment EPA-HA-OAR-2002-0058-2808.1, excerpt 12 for further subcategorization based on coal rank.
EPA acknowledges the additional data suggestions for coal quality, but the current methodology for assessing fuel variability requires EPA to link the emissions of best performing units with their variability. In our fuel variability analysis we focused on fuel analysis data that was reported to be fired at a specific best performing unit and we did not consider general fuel quality data that was not attibributed to best performing units.

Commenter Name: Lee B. Zeugin
Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 89

Comment: As discussed above, the Agency identified five basic types of units as subcategories for the three HAP groups that EPA termed fuel-dependant (i.e., PM , HCl and Hg). However, we do not believe EPA's analysis was sufficiently detailed, especially with respect to PM emissions. For coal-fired units, EPA subsequently identified three additional subcategories for organic emissions: (1) pulverized coal (PC) units; (2) stokers designed to burn coal; and (3) fluidized bed units designed to burn coal. The way the coal is prepared/processed for these three types of furnaces is fundamentally different. While potential PM (fly ash) emissions may be fuel dependent, an identical PM control technology (e.g., electrostatic precipitator) will perform quite differently on a stoker unit as compared to a PC unit. For a PC unit, the fuel must be ground to a fine powder (i.e., pulverized) in the coal mills before being blown into the furnace. On the other hand, stoker boilers take in much larger-sized pieces of coal. Because PC units require the fuel to be so fine, the PM emissions are more difficult to control. Likewise, fluidized bed units require yet a different coal preparation and also require the addition of limestone to the combustion bed. The characteristics of fluidized bed combustion yield uncontrolled PM emissions that are different from both PC units and stoker boilers. Because these different types of units process the coal differently, their PM emission characteristics are fundamental different. For example, a baghouse installed on a stoker unit could reduce PM emissions to a level that is barely measureable. On the other hand, that same baghouse installed on a similarly-sized PC unit would have higher PM emissions simply because finer coal particles are required by the PC burners. We do not believe the Agency adequately addressed this issue; rather, EPA appears to have simply assumed that all three furnace types should be treated equally with respect to the PM emission limit for coal combustion.

Response: The EPA disagrees with the commenters suggestion to further subcategorize for particulate matter emissions from solid fuel units based on the design of the combustor. Although there may be variation in the amount of pollutants emitted, the type of pollutants emitted will be similar and similar control technologies may be used. EPA recognizes that some units may obtain a higher removal efficiency but other units may be able to install control devices in parallel to meet similar emission limits.

Comment: The biomass subcategories are poorly defined which raises doubts if USEPA has properly categorized the Boilers and Process Heaters into each subcategory. Then the units that make up the MACT Floor for each subcategory are suspect as well. Definitional issues and related questions include:

Stokers are defined in §63.7515 as mechanical stokers that are not typically used for biomass. stokers are widely used for wood biomass and seem to be defined under Boiler in the proposed regulations.

Are air-swept stoker fired units included in the Stoker subcategory or the Suspension Burner! Dutch Oven subcategory?

Are Suspension Boilers (definition) the same as Suspension Burners (subcategory)?

A Suspension Burner for biomass is typically like a Pulverized Coal Burner where the fuel is conveyed to the boiler by an airstream and burned in suspension.

Does the subcategory Suspension Burner! Dutch Oven include both Dutch Ovens and Suspension Burners! or must a unit employ both firing methods to be included?

It is surprising that a Suspension Burner (like pulverized coal) and a Dutch Oven would have similar combustion-related emissions and be in the same subcategory. It would seem that Dutch Ovens would have more in common with Fuel Celfs in that both types are pile burners.

How does a Dutch Oven differ from a Fuel Cell as far as combustion characteristics and combustion-related emissions?

What criteria is used to place a unit in a subcategory that employs more than one biomass firing method?

Response: See final rule and preamble for revised definitions of subcategories and how to determine the subcategory for units that employ multiple firing types. We have adjusted the definition of stoker. We have retained a combined dutch oven/suspension burner category. Emissions of CO are similar between the two designs and there is not ample technical reasons provided for separating these two designs into their own unique subcategories.

Comment: One of our major concerns with the proposal is the affect of the rules on wood-fired boilers commonly used in the furniture industry.
Under current practices boilers in the furniture industry are typically small and combust a kiln-dried wood fuel which is generated during the furniture manufacturing process.

The wood fuel is very dry, burns cleanly, has a neutral CO_2 emissions scoring and has a high BTU value. However, as we understand it, the Boiler Rule EPA has proposed would combine these smaller dry-wood fuel boilers used in the furniture industry into a broader biomass subcategory that includes boilers fired by wet fuel used in other industry sectors thereby creating a single subcategory of emission sources for evaluation.

By establishing a single large group of boilers that use both dry wood fuel and wet wood fuel, EPA effectively ignores the benefits and unique characteristics of dry wood boilers by imposing a single set of emissions standards on the entire category.

Large boilers burning wet biomass fuels have historically required costly controls as a result of their inherently higher emissions. The cost for small dry fuel boilers to meet standards that have historically applied to wet biomass boilers is prohibitive.

Currently, for that same boiler in North Carolina we estimate a cost of about $1.5 million to retrofit that boiler with a scrubber add-on control end of pipe to continue operation of that boiler in North Carolina. And the incremental air quality benefit that would come from lumping dry fuel boilers into such a category is neglible. In fact, rather than make costly investments in new controls -- control facilities, a more likely outcome is that furniture manufacturers will retire their wood-fire boilers, replace them with natural gas or fuel oil combustion boilers and simply dispose of the dry wood fuel generated by the furniture manufacturing processes in landfills.

As greenhouse gas neutral fuels would be replaced by a fuel that emits substantial amounts of greenhouse gases, we estimate that at this same typical facility in North Carolina an increase in CO_2 to switch to natural gas of 10,500 tons annually.

This predictable outcome would not be consistent with the intent of the rule. To prevent this likely outcome from occurring, we request that EPA revisit the proposal and establish a distinct low moisture biomass subcategory for dry wood fuel.

Having this subcategory which considers the unique characteristics of these boilers and the heat content of dry wood fuel would enable a far more desirable economic environmental outcome.

Response: See response to comment EPA-HQ-OAR-2002-0058-2692.1, excerpt 2. EPA cannot consider costs in determing the MACT floor.

Comment: Revise the standards for biomass. We believe new standards based on fuel type, type of boiler and type of use need to be expanded. Consider woody biomass vs. agricultural biomass, geographical variance in mercury and HCl content (some areas of the country grow wood and agricultural fuels that contain lower levels of these pollutants), and whether any control technology would reduce emissions to the new limits.

Response: EPA disagrees that further subcategorization is justified based on the type of biomass. Limited data are available for each biomass type and further subcategorization would over partition the database. Further, many solid fuel units co-fire multple types of solid fuels including combinations of bio-based solid and fossil solids as well as several different types of bio-based solids.

Comment: FSI strongly agrees with these statements. However, for these same reasons, FSI strongly believes the biomass subcategory should be divided further into at least three subcategories for not only organic hazardous air pollutant (HAP) emissions, but also for PM emissions.

FSI believes that significant emission differences occur between wet and dry biomass. Certainly biomass containing more than 40 percent moisture will combust very differently than 30 percent or less moisture biomass, and the boiler design will take this difference into account. Bagasse contains between 48 percent and 55 percent moisture, which results in much different emissions for bagasse versus other wet biomass such as wood, which has on average lower moisture content. Just as coal and biomass are solid fuels that burn differently, and therefore their associated boiler design is different, so it is with wet and dry biomass fuels.

Although the HAP metals emissions are not dependent on wet versus dry biomass types, PM emissions are affected by moisture content of the fuel, since moisture content affects combustion efficiency and excess air levels, which in turn affects unburned carbon emissions. Unburned carbon, as well as ash in the biomass fuel, becomes entrained in the boiler flue gases and is measured as PM at the boiler stack. The lower combustion efficiency increases total PM emissions out the stack, but the HAP metals emissions are not increased, since the HAP metals will be emitted out the stack as PM (ash) regardless of unburned carbon amounts or combustion efficiency.

Response: See repsonse to comment EPA-HQ-OAR-2002-0058-2692.1, excerpt 2.

The EPA disagrees with the commenters suggestion to further subcategorize for particulate matter emissions from solid fuel units based on the moisture content of the fuel. Although there may be variation in the amount of pollutants emitted, the type of pollutants emitted will be similar and similar control technologies may be used. EPA recognizes that some units may obtain a higher removal efficiency but other units may be able to install control devices in parallel to meet similar emission limits. Further, many solid fuel units co-fire multiple types of solid fuels including combinations of both wet and dry biomass and biomass and coal or other fossil solids.

Comment: EPA should further subcategorize biomass on the basis of green (or wet) and dry fuels. NC DAQ test data show that PM emissions from dry wood (<20% moisture) combustion can be up to 20-50% higher than emissions from the combustion of green wood. In North Carolina, dry wood is burned in smaller boilers (<50 MM Btu/hr) in wood working industries, including furniture manufacturing. Green wood combustion sources include larger boilers (>250

MM Btu/hr) in lumber mills and pulp and paper plants that are more highly controlled. NC DAQ thinks that the dry wood-fired sources and green wood-fired sources are sufficiently different based on emissions and level of control to warrant additional sub-categorization.

Response: See response to comment EPA-HQ-OAR-2002-0058-2692.1, excerpt 2.

Comment: NPIUSA is located at the base of a spit surrounded on three sides by marine waters. The mill's source of wood fuels includes forest biomass sourced and/or stored adjacent to marine waters. As a result of this proximity to marine waters for both the mill and its fuel supplies, the higher level of chlorides in the wood and air possibly present a different emissions profile than non? coastal mills. EPA should consider the performance of coastal mills and consider whether these mills should be considered in a separate category due to regional issues. Additional testing of boilers is needed to determine the effect of marine proximity to those whose fuel sources are substantial inland.

Response: There are 36 biomass boilers in coastal areas that have reported stack test data below the new source limit and 55 biomass boilers in coastal areas below the existing source limit for the solid fuel subcategory. Based on this, EPA determined it has adequately accounted for coastal biomass fuel variability in the development of the floors for the solid fuel subcategory.

Comment: Kiln dried wood fuel has very different combustion characteristics than "wet" biomass and, as a result, our clean-burning dry biomass fuel has been assigned a unique AP-42 emission factor for air emissions characterization. Due to its lower emission rate for particulate matter (as compared to bark and wet biomass fuels typical of paper mills), dry biomass units have not historically been required to install the more complex, more costly emission controls common on wet biomass units. The typical dry biomass unit uses mechanical separation devices such as multicyclones as the only necessary pollution control. However, wet biomass units are frequently required to install higher efficiency control devices such as electrostatic precipitators to meet New Source Performance Standards. Historically, dry biomass units have been categorized separately from their wet biomass counterparts, and for good reason.

Under Clean Air Section 112(d)(1), EPA has explicit authority to develop emission standards for appropriate subcategories. Even the U.S. Court of Appeals for the D.C. Circuit has recognized the breadth and utility of the subcategorization approach:

Section 112(d)(1) authorizes the Administrator to "distinguish among classes, types and sizes of sources within a category or subcategory," and the language of subsections 112(d)(2) and (3) pervasively refers to standards for sources in each "category or subcategory." The authority to generate subcategories is obviously not unqualified; at the least it must be limited by the usual ideas of reasonableness. And there is not necessarily any guarantee that, even with suitable subcategorization, every source will be able to achieve standards that meet a lawful application of § 112(d)(3) to reasonably defined subcategories. Nonetheless, one legitimate basis for creating additional subcategories must be the interest in keeping the relation between "achieved" and "achievable" in accord with common sense and the reasonable meaning of the statute. [Sierra Club v. EPA, 479 F.3d 875 (D.C. Cir. 2007) (J. Wiliams, concurring).]

By lumping dry and wet biomass units into a single "Biomass" category, the EPA has failed to recognize the unique attributes of our bona fide fuel category. Because dry fuel combustion units have historically not required complex control, our category is distinct from other biomass units in its emission characteristics for particulate matter. Precedence for subcategorizing broadly-defined fuel types has been established in the rule by EPA's designation of "Gas 1" and "Gas 2" categories. We request the development of a separate category for dry biomass fuels based on the same principle.

Response: The EPA disagrees with the commenters suggestion to further subcategorize solid fuel units based on the moisture content of the fuel. Although there may be variation in the amount of pollutants emitted, the type of pollutants emitted will be similar and similar control technologies may be used. EPA recognizes that some units may obtain a higher removal efficiency but other units may be able to install control devices in parallel to meet similar emission limits. Further, many solid fuel units co-fire multiple types of solid fuels including combinations of both wet and dry biomass and biomass and coal or other fossil solids. EPA also notes that what has historically been required under older permits does not necessarily reflect a MACT level of control and MACT subcategories do not need to be identical to the breakdowns used in the AP-42 program.

Comment: EPA should further subcategorize biomass units by combustor type for setting organic HAP MACT floors.

ERC supports EPA's decision to subcategorize major source biomass boilers by combustor type, but the Agency does not go far enough. Combustion distinctions exist within the stoker and fluidized bed designs which make further subcategorization into fixed, traveling, and rocker type stokers and bubbling and fluidized bed type combustors appropriate for combustion related (organic) HAPs. Precedence for subcategorizing to set CO limits is found in EPA's Large

Municipal Waste Combustor (MWC) MACT rule which subcategorizes MWCs into 13 different combustor types, including a distinction between bubbling and fluidized bed combustors. (71 FR 27335, Table 3). EPA should do likewise in the Major Boiler MACT rule.

Response: EPA disagrees that further subcategorization is justified. The commenter does not provide data or sufficient justification for further spllitting out the fluidized bed subcategory and without that data to support the argument EPA determined that this approach would create a very fractioned database.

Subcategories: Liquid

Comment: It does not seem appropriate to impose the same MACT PM emission standard for all types of oil, as No. 6 and No. 2 oil have very different ash content and fuel characteristics, and these differences are likely more pronounced for ultralow sulfur oils. The MACT analysis should be performed separately for the different major types of oil (i.e. No. 6 Oil, No. 2 Oil, UltraLow Sulfur Diesel Oil), and the resulting emission standards should be determined separately. All fuel oils should not all be lumped into a single classification and as a result be subject to the same emission standard.

Response: See response to comments EPA-HQ-OAR-2002-0058-2769.1, excerpt 3 , EPA-HQ-OAR-2002-0058-2960.1, excerpt 57 and EPA-HQ-OAR-2002-0058-2863.1, excerpt 22.

Comment: EPA should create two subcategories within the liquid-fueled emission sources and set separate MACT floor limits for each.

The Federal Register notice at page 32017 (second column) describes EPA's rationale for subcategorizing boilers and process heaters.

"We have identified the following 11 subcategories for organic HAP:
Pulverized coal units,
Stokers designed to burn coal,

Fluidized bed units designed to burn coal,
Stokers designed to burn biomass,
Fluidized bed units designed to burn biomass,
Suspension burners/Dutch Ovens designed to burn biomass,
Fuel Cells designed to burn biomass,
Units designed to burn liquid fuel,
Units designed to burn natural gas/refinery gas,
Units designed to burn other gases,
and Metal process furnaces.

These subcategories are based on the primary fuel that the boiler or process heater is designed to burn." [emphasis added]

The Federal Register notice, in the third column of the same page, also states:

"This would ensure that each boiler and process heater is subject to emissions standards calculated on the basis of the best performing units with similar design and operation."

Although there are three subcategories for coal units, four subcategories for biomass units, and three subcategories for gas-fired units (including metal process furnaces), there is only one category for all liquid-fired units. The emissions data published by EPA demonstrate that there are fundamental differences in the design, operation and emissions characteristics of residual oil-fired units and distillate oil-fired units such that two subcategories are warranted in the liquid-fired unit category. Only by creating two subcategories will EPA "ensure that each boiler . . . is subject to emission standards calculated on the basis of the best performing units with similar design and operation."

For example, Table 7 (CO Fuel by Floor) of Appendix C-2 of the April 2010 ERG Memorandum lists the units determining the MACT floor value for carbon monoxide (CO). Of the 14 units comprising the best-performing 12%, all burn distillate oil only (No. 2 distillate or jet fuel), except one unit -- and that one unit appears to represent an outlier value. [MACT Floor Analysis (2010) for Boilers an Process Heaters-Major Sources NESHAP] And in Table 2 (HCI Fuel by Floor) of Appendix C-2, the top-performing units burn a wide variety of fuels, including No. 4 oil, animal fats, vegetable oil, anhydrides waste liquids, No. 2 oil, blast furnace gas, and natural gas, with the greatest majority of the identified units burning a mixture of No. 2 distillate oil and aviation fuel. This same pattern is repeated in Table 3 (pM-Filter Fuel by Floor) of Appendix C-2 where none of the units identified in the top-performing 12% combust residual oil. Two units combust waste liquids, and all the remaining top performing units combust diesel fuel or No. 2 distillate fuel.

This failure to subcategorize liquid-fueled sources is of particular concern given that EPA subcategorized liquid fuels during the ICR process. For example, Table.2 in Section 2. 3 of the March 2010 ERG Memorandum, entitled "Categorical Fuel Material Hierarchy," lists a category for "heavy liquids" and "light liquids". Table B.I of the same document, entitled "Fuel Category Constituents," lists a variety of liquid fuels and wastes, once again divided in two categories -- "residual/heavy liquids" and "distillate/light liquids." The information contained in Part B of

Supporting Statement for ICR No. 2286.01, Appendix I -listing the 187 units tested as part of the ICR process - also divides the liquid-fueled units into "liquid (heavy)"and "liquid (light)" . Yet, EPA's proposed rulemaking provides no justification for discontinuing this differentiation between the two types of liquid fuel.

Just as stokers, fluidized bed units and Dutch ovens are configured differently, light oil and residual oil units are designed with different components. There are significant differences between the design for the combustion nozzles, flame temperatures, fuel forwarding pumps and controls, and fuel handling techniques of distillate-oil and residual-oil units. An entity specifically designing a boiler for each fuel would specify different tube surface area and spacing to accommodate the differences in heat and ash content between the two types of fuels.

To ensure that residual-oil units are treated consistently and in accordance with the stated intentions of the MACT process, EPA should re-establish a subcategory for residual-oil units and a subcategory for distillate-oil units, dividing the two subcategories in a manner consistent with Table B.I found in the March 2010 ERG Memorandum. Once these subcategories have been re-established, EPA should recalculate the MACT floor emission level for each subcategory of liquid-fueled units.

Response: EPA disagrees that residual oil-fired units require a separate subcategory. First, while EPA did request that units indicate whether they combust light or heavy liquid fuel in the ICR, this in no way impacts the final subcategories. Those decisions are made separately, regardless of the structure of the ICR. While there are design differences between light and heavy liquid units, the subcategories established by EPA, even for the various types of solid fuel-fired units of various designs, do not distinguish between designs for the fuel-based pollutants (Hg, PM, and HCl). That is, all solid fuel units are part of the same subcategory for the fuel based pollutants. While the subcategories have changed for coal and biomass units since proposal, the same general approach was followed at proposal. That is, all coal units had the same proposed limits for the fuel-based pollutants, and all biomass units had the same proposed limits for the fuel-based pollutants. Therefore, for the fuel based pollutants, covering all liquid fuel units within a single subcategory is consistent with the treatment of solid fuel units. For combustion-based pollutants (CO and dioxin/furan), the standards are based, in all cases, on a pool of best performers that included at least one-half residual oil units. Therefore, EPA is maintaining the same subcategorization approach for liquid fuel units.

Comment: Subcategorize the proposed liquids subcategory into light liquids and heavy liquids and apply work practice requirements to the clean-burning light liquids subcategory. Setting an emission limit based on distillate fuel oil emissions is not justifiable for the entire subcategory. Only a PM limit is warranted for the heavy oil subcategory.

Response: See response to comments EPA-HQ-OAR-2002-0058-2769.1, excerpt 3 , EPA-HQ-OAR-2002-0058-2960.1, excerpt 57 and EPA-HQ-OAR-2002-0058-2863.1, excerpt 22.

Commenter Name: Arthur N. Marin
Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 11

Comment: Elemental analyses of fuel oils recently conducted by NESCAUM indicate that emissions from #2 distillate oil are significantly lower in mercury and other trace metals than EPA's AP-42 emission factors would otherwise suggest. Trace metals were measured in various petroleum products sampled in the Northeast, including #6 residual fuel oil, #2 distillate oil, ultra-low sulfur heating oil, and bio-diesel. See submittal for Table 1 showing the trace metal results for #2 distillate oil and #6 residual oil, which are presented as input-based emission rates. Based on NESCAUM's fuel sampling work, the more refined petroleum products have a different composition and are lower in nickel (Ni) and vanadium (V) than the heavier #6 residual oil. The fuel sampling also found very low levels of mercury (Hg) in petroleum products, and underscored the need for EPA's National Emissions Inventory to be updated for several metals, including mercury, nickel, and vanadium. Furthermore, based on compliance data, when burned in a commercial or industrial boiler to produce heat, different blends of petroleum can have very different fine particle emission rates due to the combustion design of the heating system and the fuel composition.
See submittal for a bar chart of Figure 2 shows the particulate matter (PM) emission rates for different combustion systems and fuels used in heating equipment based on analysis conducted recently by the New York State Energy Research and Development Authority (NYSERDA). Currently, #2 distillate oil is the most common fuel for heating in the Northeast, after natural gas, and has a PM emission rate of approximately 0.008 lb/mmBtu. Ultra-low, or 15 ppm, sulfur heating oil has a PM emission rate of 0.000099 lb/mmBtu, about the same as the emissions rate for natural gas-fired boilers. Number 6 residual fuel oil is commonly used in large buildings and has PM emission rate twice that of a boiler burning #2 distillate oil.
Based on these data, NESCAUM believes that EPA can achieve its emission targets by regulating ultra-low sulfur #2 distillate oil with the same regulatory strategy EPA proposed for natural gas.

Response: See response to comments EPA-HQ-OAR-2002-0058-2769.1, excerpt 3 , EPA-HQ-OAR-2002-0058-2960.1, excerpt 57 and EPA-HQ-OAR-2002-0058-2863.1, excerpt 22.
Response to unique comment: EPA can achieve its emission targets by regulating ultra-low sulfur #2 distillate oil with the same regulatory strategy EPA proposed for natural gas

EPA disagrees with incorporating the same regulatory strategy as natural gas for units firing ultra-low sulfur #2 distillate oil. EPA did look at its database to determine if units firing ultra low sulfur fuel oil, based on a cutoff of 15 ppm (0.0015 wt. %) sulfur content specified by

NESCAUM. At this threshold there was not any standardized fuel analysis data for metallic HAP or Hg available to establish a separate MACT floor computation. EPA did have particulate matter data available for one test based on the firing of ultra low sulfur fuel oil, but the particulate matter results for this unit were much higher than the particulate matter resulting from the commenter's suggestions or the particulate matter data for natural gas.

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 159

Comment: The liquid subcategory should be divided into light and heavy liquid subcategories. The light liquids would be those liquids with a 90% ASTM D-86 distillation of < 640 °F. This definition would split the liquids subcategory such that Number 2 fuel oil would be in the light liquids subcategory and heavier fuels would be in the heavy liquids subcategory. From the available data, there is a difference in emissions such as PM, but EPA's data is relatively limited, does not consider all operations, and suffers from many data quality issues. Based on a review of the top performing liquid boilers, however, those that are correctly categorized as liquid boilers are typically firing light liquids such as distillate oil (which is equivalent to home heating oil), which indicates a difference in emissions from heavy versus light liquid boilers. As not all boilers will be able to fuel switch due to fuel availability, EPA should gather additional data to support subcategorization of liquid boilers.

Residual fuel oils typically contain higher levels of ash and somewhat higher levels of metals See AP-42 factors for oil firing, Section 1.3.1. However, HAP metals content in residual fuel oil is strongly influenced by crude oil processed at a given refinery, because these metals volatilize only at very high temperatures and thus typically stay in the bottoms in crude units or in Vacuum units. Thus, the level of metals in a crude oil will be directly related to the metals in residual fuel oil. {citation} than do distillate fuel oils. The combination of these characteristics means that residual fuel oil-fired boilers and process heaters have higher emissions of metal HAPs and PM than boilers and process heaters burning distillate fuel oils (light liquid fuels).

Residual fuel oils also have significantly different firing properties than do distillate fuel oils. The combustion characteristics of light and heavy liquids are different, because these fuels have very different flow/viscosity and atomization characteristics and different energy contents. Per API, typical residual fuel has about 7% more energy per gallon than a distillate fuel oil. As a result of these property differences, at a minimum, heavy fuel oil firing requires different burner tips then are needed when firing lighter fuel oils. The heating value and flame height differences between these fuels may also impose unit design and operating constraints.

In addition, residual fuel-fired boilers must operate a soot blowing cycle on a periodic basis to maintain their heat transfer efficiency, during which opacity and PM levels increase. While the liquids database does not appear to include any data characterizing soot blowing emissions, the proposed emission limits would apply during that time and thus these emissions must be considered. It is, therefore, clear that metal HAP and PM emissions at least, distinguish residual fuel-fired units from distillate-fired units. Indeed, EPA has recognized this fact by creating an implicit subcategory for residual-fuel fired units in the proposal by requiring in § 63.7525 that residual oil-fired process heaters and boilers (but not distillate units) install a PM CEMS. Thus, from an equipment design and operations standpoint as well as an emissions standpoint, there is a clear distinction between boilers and process heaters firing light liquids versus those that fire heavy liquids. By splitting the liquid subcategory and applying work practice requirements to the new light liquids subcategory (as most emissions from these units are so low that they cannot be reliably measured), the Agency would incentivize sources to switch to light liquids, where they can.

Response: Data for the best performing units in the subcategory show that the units achieved the levels of emissions upon which the floors are based. While units blowing soot were not identified as best performers, emission controls can be installed to meet the floor levels, or sources may choose to change their fuel mix to comply with the standards. For additional information see the response to the following comment, DCN: EPA-HQ-OAR-2002-0058-1869.1, except 4.

Commenter Affiliation: University of Virginia
Document Control Number: EPA-HQ-OAR-2002-0058-2769.1
Comment Excerpt Number: 3

Comment: UVA believes EPA should reconsider the decision to place all liquid-fired fuels into one subcategory. In fact, early EPA technical documentation appears to indicate that two subcategories of liquid fuels were considered (see ERG "Baseline Emission Factor" memo Docket #EPAHQ-OAR-2002-0058-0802) but only one liquid fuel subcategory appears in the proposed rule.

Liquid fuels, by regulatory definition, include distillate oil, residual oil, on-spec used oil, and biodiesel. The oils may vary from ultralow sulfur diesel (ULSD) to #6, with likely varying concentrations of ash, chlorine, and mercury. The table below provides heating values and densities for several of these fuels.

[See submittal for table of Fuel Oil Heating Values]

Heating Value (Btu/gal) & Density (lb/ft3) Source: www.engineeringtoolbox.com

Maximum Ash Content Source: Colonial Pipeline Specifications and 2003 ASTM book: Fuels and Lubricants Handbook: Technology, Properties, Performance.

With typical heating values and densities, and assuming all constituents in the fuel are emitted (a realistic scenario for many liquid fuel fired units without air pollution control devices), it is possible to convert the emission limits into fuel concentrations. The proposed PM emission limit of 0.004 lb/MMBTU is equal to approximately 0.008% ash in the fuel. This is below the specification for maximum ash content in these fuels. Therefore, if the fuels barely meet the specifications and burn without any soot formation, ash in the fuel will still lead to PM emissions exceeding the limit, without some type of control device. Distillate oils may be able to meet the PM limits without controls, while heavier fuels will likely need to install PM controls.

Response: EPA disagrees that further subcategorization by type of liquid fuel is warranted. EPA may not subcategorize on the basis of emissions of the unit, so although the particulate matter or HAP emitted from distillate vs. residual fuel oil may vary this is not a valid reason for subcategorizing. EPA maintained separate baseline emission factors for light vs. heavy liquids in order to more accurately estimate the baseline emissions and emission reductions of the standard but this baseline emission analysis does not imply that the liquid fuel category should be separated.

Comment Excerpt Number: 7

Comment: Subcategorize the proposed liquids subcategory into light liquids and heavy liquids and apply work practice requirements to the clean-burning light liquids subcategory. Setting an emission limit based on distillate fuel oil emissions is not justifiable for the entire subcategory. Only a PM limit is warranted for the heavy oil subcategory.

Response: See response to comments EPA-HQ-OAR-2002-0058-2769.1, excerpt 3 , EPA-HQ-OAR-2002-0058-2960.1, excerpt 57 and EPA-HQ-OAR-2002-0058-2863.1, excerpt 22.

Commenter Name: William R. Ermatinger
Commenter Affiliation: Northrop Grumman
Document Control Number: EPA-HQ-OAR-2002-0058-2506.1
Comment Excerpt Number: 29

Comment: It is inappropriate to include residual oil-fired steam boilers, distillate oil-fired steam boilers, other liquid fuel-fired steam boilers and liquid fuel-fired process heaters in the same subcategory, and it is erroneous to establish a single set of emission limits that apply to all such units in the subcategory. Separate subcategories should be established for boilers and process heaters based on specific fuels utilized, type of combustion unit, heat input rating, and nature of the use or application of a boiler, and separate emission limits and work practice standards should be established for each such subcategory based on valid field testing data.

Steam boilers and process heaters are fundamentally different pieces of equipment having different designs, functions, purposes, operating characteristics and emissions. Even within the grouping of liquid fuel-fired steam boilers, there is a wide variation in equipment design, sizes, applications, operating characteristics, fuel types and emissions. It is not reasonable to expect that all units in this category, as defined by EPA, would be capable of meeting a "one size fits all" set of emission limitations and work practice standards. At a minimum, separate subcategories should be established for boilers and for process heaters, and each of those subcategories should be further subdivided by size range, fuel type and the other differentiating factors mentioned above. An existing example demonstrating the feasibility of such subdivision or source types can be found in EPA's new source performance standards (NSPS) for fossil fuel-fired steam generating units, found at 40 CFR Parts D, Da. Db and Dc.

Response: While the commenter cites several reasons why separate subcategories might be warranted for liquid fuel-fired combustion units, and states that a single subcategory is not reasonable, the commenter provided little support for the conclusions provided. For additional information see the responses to the following comments, DCN: EPA-HQ-OAR-2002-0058-3213.1, excerpt 159 and DCN: EPA-HQ-OAR-2002-0058-1869.1, excerpt 4.

Commenter Name: Robert D. Bessette

Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 55

Comment: CIBO also supports EPA subcategorizing for light versus heavy liquid fuels. There are strong technical arguments why EPA should split the liquids into separate sub-categories and not the gases. Fuel gases don't vary much in HAP content with the possible exception of mercury. Liquid fuel HAP contents are likely to vary a good bit with the main division being light (DO) versus heavy (RO).

Response: See response to comments EPA-HQ-OAR-2002-0058-2769.1, excerpt 3 , EPA-HQ-OAR-2002-0058-2960.1, excerpt 57 and EPA-HQ-OAR-2002-0058-2863.1, excerpt 22.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 57

Comment: The liquids subcategory should be divided into light and heavy liquids subcategories. The light liquids would be those liquids with a 90% ASTM D-86 distillation of < 640 degree F. This definition would split the liquids subcategory such that Number 2 fuel oil would be in the light liquids subcategory and heavier fuels would be in the heavy liquids subcategory. From the available data, there are differences in sulfur and PM emissions that make such a split necessary. EPA's data and the proposed emission limits indicate little difference in HAP emissions between liquids and gases, but the EPA data is relatively limited, does not consider all operations and suffers from many of the same data quality issues discussed for gas-fired units. The differences between light and heavy liquid combustion are generally recognized. For instance, Northeast States for Coordinated Air Use Management (NESCAUM) concluded the following for light liquids reducing the sulfur content of heating oil from 2,500 ppm to 500 ppm lowers SO2 emissions by 75 percent, PM emissions by 80 percent, NOx emissions by 10 percent, and CO_2 emissions by 1 to 2 percent. Other benefits associated with lowering the sulfur content of heating oil include heating system efficiency improvements,..." [Footnote: NESCAUM, Low Sulfur Heating Oil in the Northeast States: An Overview of Benefits, Costs and Implementation Issues, December 2005 (included in Attachment I to these comments)] For all the same reasons applicable to Gas 1 fuels, only work practice standards are feasible to measure and enforce for light liquids or for all but PM for heavy liquids.

Response: EPA disagrees that further subcategorization by type of liquid fuel is warranted. EPA may not subcategorize on the basis of emissions of the unit, so although the HAP emitted from distillate vs. residual fuel oil may vary this is not a valid reason for subcategorizing. Units firing distillate fuel are still included in the liquid subcategory. As such they are subject to the emission limits that are applicable to liquid fuel fired units. However, we do recognize that emissions from firing distillate oil are lower than from firing residual oil, and reflect this in the rule. Units firing distillate oil may demonstrate compliance with fuel analysis in lieu of a stack test to reduce compliance burden.

Comment: Residual fuel-fired boilers must operate a soot blowing cycle on a periodic basis to maintain their heat transfer efficiency, during which opacity and PM levels increase. While the liquids database does not appear to include any data characterizing soot blowing emissions, the proposed emission limits would apply during that time and thus these emissions must be considered. It is, therefore, clear that metal HAP and PM emissions at least, distinguish residual fuel-fired units from distillate-fired units. Indeed, EPA has recognized this fact by creating an implicit subcategory for residual-fuel fired units in the proposal by requiring in 63.7525 that residual oil-fired process heaters and boilers (but not distillate units) with greater than 250 MMBTU/hr design heat input install a PM CEMS.

Thus, from an equipment design and operations standpoint as well as an emissions standpoint, there is a clear distinction between boilers and process heaters firing light liquids versus those that fire heavy liquids. By splitting the liquid subcategory and applying work practice requirements to the new light liquids subcategory, the Agency would incentivize sources to switch to light liquids, where they can.

Recommendation: Split the proposed liquid subcategory into a light liquid and heavy liquid subcategory and apply work practice requirements, except possibly for PM in the heavy liquids subcategory.

Response: See response to comments EPA-HQ-OAR-2002-0058-1869.1, excerpt 4 and EPA-HQ-OAR-2002-0058-3213.1, excerpt 159.

Commenter Affiliation: Boise, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2855.1
Comment Excerpt Number: 1

Comment: Boise has a total of nineteen boilers located at its five mills which would be subject to the proposed Boiler MACT rule. Nine of these boilers are capable of burning only natural gas and would be subject to the rule's "Gas 1" subcategory annual tune-up requirements. Five additional boilers are capable of burning a combination of natural gas and fuel oil and, as currently operated, would be subject to the "units designed to burn liquid fuel" subcategory. However, given the significant cost to install controls on these boilers to meet the limits for liquid fuel boilers, it is likely that their capability to burn fuel oil would be limited. as outlined in the rule, so that they would also be Gas 1 subcategory boilers; in which case, they would also be subject to the annual tune-up requirement.

Response: EPA has adjusted the subcategory definitions to be based on actual fuel usage.

Commenter Name: Gordon M. Smith

Comment Excerpt Number: 1

Comment: The liquids subcategory should be divided into light liquids (distillate oil) and heavy liquids (residual oil) subcategories, following the proposed definitions in §63.7575. EPA's data and the proposed emission limits indicate little difference in HAP emissions between liquids and gases, but the EPA data is relatively limited and does not consider all operations.
Residual fuel oils (heavy liquid fuels) typically contain higher levels of ash and somewhat higher levels of metals[See AP-42 factors for oil firing, Section 1.3.1.] than do distillate fuel oils. The combination of these characteristics means that residual fuel oil-fired boilers and process heaters have higher emissions of metal HAPs and PM than boilers and process heaters burning distillate fuel oils (light liquid fuels).
Residual fuel oils also have significantly different firing properties than do distillate fuel oils. The combustion characteristics of light and heavy liquids are different, because these fuels have

very different flow/viscosity and atomization characteristics and different energy contents. Typically, residual fuel has about 7% more energy per gallon than a Number 2 fuel oil. As a result of these property differences, at a minimum, heavy fuel oil firing requires different burner tips then are needed when firing lighter fuel oils. The heating value and flame height differences between these fuels may also impose unit design and operating constraints.
In addition, residual fuel-fired boilers must operate a soot blowing cycle on a periodic basis to maintain their heat transfer efficiency, during which opacity and PM levels increase. While the liquids database does not appear to include any data characterizing soot blowing emissions, the proposed emission limits would apply during that time and thus these emissions must be considered. It is, therefore, clear that metal HAP and PM emissions at least, distinguish residual fuel-fired units from distillate-fired units. Indeed, EPA has recognized this fact by creating an implicit subcategory for residual-fuel fired units in the proposal by requiring in §63.7525 that residual oil-fired process heaters and boilers (but not distillate units) having heat input capacities greater than 250 MMBtu per hour install a PM CEMS.
Thus, from an equipment design and operations standpoint as well as an emissions standpoint, there is a clear distinction between boilers and process heaters firing light liquids versus those that fire heavy liquids.

Response: See response to comments EPA-HQ-OAR-2002-0058-1869.1, excerpt 4 and EPA-HQ-OAR-2002-0058-3213.1, excerpt 159.

Document Control Number: EPA-HQ-OAR-2002-0058-3179
Comment Excerpt Number: 2

Comment: DGC proposes a heavy liquid fuel subcategory. In 75 FR32017 (June 4, 2010), EPA discusses reasons for incorporating subcategories into the proposed rule where it states, "Therefore, because different types of units have different emission characteristics which may influence the feasibility of effectiveness of emission control, they should be regulated separately (i.e., subcategorized)." DGC agrees with this statement and therefore proposes a heavy liquid fuel subcategory. The uniqueness of our liquid fuels (all are lignite derived) and their unclassified nature in the current rule proposal begs for a separate subcategory. The liquid fuels combusted include tar oil, naphtha, and crude phenol which are all recovered via the gasification process. The standards as proposed for existing liquid-fired boilers are not technically achievable for our facility configuration.

Response: EPA disagrees that further subcategorization of liquid fuels is warranted. The commenter did not provide sufficient data or technical justfication for a separate subcategory for these fuel types.

Comment Excerpt Number: 20

Comment: In addition, residual fuel fired boilers operate a soot blowing cycle on a periodic basis, typically daily, during which opacity and PM levels are increased significantly for a duration of up to 2 hours at some units at HOVENSA. Soot blowing is required to maintain the energy efficiency of the boiler. Indeed, EPA has recognized the higher PM emissions from residual fuel oil by creating an implicit subcategory for residual fuel by requiring in § 63.7525 that residual fuel fired heaters and boilers (but not distillate units) install a PM CEMS. The preamble indicates that residual fuel oil is also subject to a 10% opacity limit, but it is less clear how the rule proposes to implement the statement in the preamble.16 Soot blowing adds to the significant operation differences between residual and distillate fuel oils as regards particulate matter emissions.
[Footnote 15: Soot blowing is a standard industry practice for residual fuel oil fired equipment. Soot blowing maintains the fuel efficiency of the equipment by periodically cleaning the heater tubes. If soot blowing is not performed, the amount of fuel combusted increases substantially because heat transfer is impeded across the boiler tubes, so that more energy is required to make steam or heat the product. A more commonplace example of this is the need to clean air conditioning units, so that heat transfer is not impeded.]
[Footnote 16: HOVENSA specifically requests that EPA address this point more clearly in any final rule, and that residual fuel oil be exempted from this standard and the PM standard during soot blowing.]

Response: See response to comments EPA-HQ-OAR-2002-0058-1869.1, excerpt 4 and EPA-HQ-OAR-2002-0058-3213.1, excerpt 159.

Commenter Affiliation: Hovensa LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 21

Comment: As EPA noted, fuel switching does not necessarily result in lower HAP emissions of all HAPs, which is the case for residual fuel oil combustion vs. distillate. For example, mercury in residual fuel oil is typically as low as (or lower) than in distillate fuel oil or even some gases for the converse reason that heavy metals concentrate in residual fuel oil. Likewise, the True Vapor Pressure of residual fuel oil is extremely low and, as a corollary, so is the volatile organics content of this fuel.17 18 Table 7-1-2 of the AP-42 emissions factor handbook reports that No. 6 fuel oil has a TVP of .00006 psi at 70oF vs. .009 for distillate fuel oil and 8 or more for gasoline. In view of the fact that combustion efficiency of residual fired heaters and boilers should be equivalent to distillate or gas fired units, emissions of volatile organic HAPs should be very similar to or (more likely) lower than distillate fuels.19
Residual fuel oil has significantly different firing properties than does distillate fuel oil or natural gas. As EPA correctly observed in the preamble, a burner cannot fire a different fuel without being retrofitted. A switch to a different fuel requires significant changes to the burner and can also require changes to the firebox to optimize combustion. 20 A firebox modification requires

very substantial rebuilds to the heater or boiler and is not practicable for most sources. The combustion characteristics change is less dramatic between residual fuel oils and distillate fuels, but is still significant because distillate and residual fuels have very different flow/viscosity and atomization characteristics and different energy contents. Typically, residual fuel has about 7% more energy per gallon than a No. 2 Oil. At a minimum, residual fuel oil requires different burner tips because of the physical differences between residual and distillate fuels. The heating value and flame height differences between these fuels may impose unit design constraints.
We also note that the residual fuel oil is more abrasive than distillate fuels. The effect of this is that the holes in the burner tips on residual fuel oil burners will wear more quickly than those in other services.
This results in less effective atomization of the residual fuel oil as the holes slightly enlarge. Residual fuel oil also tends to plug burner tips more frequently, again resulting in improper atomization and higher CO emissions. Nothing in the EPA database captures this kind of longer term degradation in performance for residual fuel oil burning performance.

[Footnote 17: "Volatility is indicated by a substance's vapor pressure. It is a tendency of a substance to vaporize or the speed at which it vaporizes. Substances with higher vapor pressure will vaporize more readily at a given temperature than substances with lower vapor pressure." http://www.epa.gov/iaq/voc2.html]
[Footnote 18: EPA used VOC as a surrogate in evaluating the emissions benefits of this rule for organic HAPS. We note that the methane is not defined as a VOC, so that it is difficult to compare gas and fuel oil in this context. However, Table 10 of the preamble shows very small VOC emissions decreases from the impact of this rule, confirming the relatively low VOC (as defined) content of residual fuel oil.]
[Footnote 19: We note that in effect forcing a switch to distillate fuel oil from residual fuel oil results in environmental "collateral damage." Distillate fuel oil production is more energy intensive and combustion emissions are higher. CO_2 is also very significant increased because of the need to hydrotreat distillates to lower sulfur levels. This is largely because the process to make hydrogen splits hydrogen from a hydrocarbon, resulting in CO_2 emissions.]
[Footnote 20: Flame heights differ between fuels. Combustion is optimized when the flame height is about 2/3rds of the firebox height. Any change in fuel will change the optimal combustion design of the firebox.]

Response: See response to comments EPA-HQ-OAR-2002-0058-1869.1, excerpt 4 and EPA-HQ-OAR-2002-0058-3213.1, excerpt 159.

Commenter Name: Christopher S. Colman
Commenter Affiliation: Hovensa LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 22

Comment: Residual fuel oil is significantly lower in cost that distillate fuel and, as noted above, does not necessarily result in a higher level of all HAP emissions. Demand for light distillate fuels has risen significantly worldwide, while demand for residual fuel oils has fallen. The effect

is that the cost of distillate fuels is significantly higher than residual fuels—ranging between 20 and 40 dollars per barrel over the last 5 years, adjusted for the approximately 7% higher energy content of residual fuel oil. (See submittal for cost differential figure 4)
The differentials have narrowed since 2008 but remain in the vicinity of $20/bbl.
The cost differential between distillate and residual fuel oil is extremely significant to the facilities that combust these fuels. For example, a facility combusting 1MM barrels of residual fuel oil per year will have added fuel costs of 20 to 30 million dollars annually to burn distillate fuel—costs which are not faced by facilities with access to natural gas. By lumping distillate and residual fuel oil combustors together in setting MACT floors, despite their very significant differences in emissions characteristics of the fuels, EPA is effectively setting a standard that requires a fuel switch, despite extensive language in the preamble disclaiming this intent. Forcing a switch to distillate fuels, in combination with the control costs that this rule imposes, will cripple or close these facilities that rely on residual fuel oil combustion.
[Footnote 22: "For the reasons discussed above, we decided that fuel switching to cleaner solid fuels or to liquid or gaseous fuels is not an appropriate criteria for identifying the MACT floor emission levels for units in the boilers and process heaters category." 75 FR at 30219.]

Response: EPA may not consider cost impacts when establishing the floor. EPA disagrees that further subcategorization by liquid fuel type is warranted. As the commenter suggests the decision to purchase residual fuel oil is based on cost and EPA may not subcategorize by cost. No technical design differences between units designed to burn distillate vs. residual fuels were noted to provide the basis for further subcategorization.

Commenter Name: Michael Hutcheson

Document Control Number: EPA-HQ-OAR-2002-0058-2803.1
Comment Excerpt Number: 27

Comment: US EPA should divide the liquid fuel subcategory into petroleum based fuels and byproduct based fuels.

The only detectable Hg in stack test data used for liquid MACT floor development came from sources burning non-petroleum fuels (bio-fuels and BFG). The only exception was the Consolidated Edison Boiler 118 in New York which is reported as having a Fabric Filter and sorbent injection but still showing detectable levels of Hg post control. As such the test data for this source is suspect. Ameren believes US EPA should revise the liquid fuel source category to distinguish between petroleum based sources and by-product fuels used at individual facilities.

Response: See response to comment EPA-HQ-OAR-2002-0058-3179, excerpt 2.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 79

Comment: The liquid subcategory should be divided into light and heavy liquid subcategories. The light liquids would be those liquids with a 90% ASTM D-86 distillation of < 640 °F. This definition would split the liquids subcategory such that Number 2 fuel oil would be in the light liquids subcategory and heavier fuels would be in the heavy liquids subcategory. From the available data, there is a difference in emissions such as PM, but EPA's data is relatively limited, does not consider all operations, and suffers from many data quality issues. Based on a review of the top performing liquid boilers, however, those that are correctly categorized as liquid boilers are typically firing light liquids such as distillate oil (which is equivalent to home heating oil), which indicates a difference in emissions from heavy versus light liquid boilers. As not all boilers will be able to fuel switch due to fuel availability, EPA should gather additional data to support subcategorization of liquid boilers.

Residual fuel oils typically contain higher levels of ash and somewhat higher levels of metals [See AP-42 factors for oil firing, Section 1.3.1. However, HAP metals content in residual fuel oil is strongly influenced by crude oil processed at a given refinery, because these metals volatilize only at very high temperatures and thus typically stay in the bottoms in crude units or in Vacuum units. Thus, the level of metals in a crude oil will be directly related to the metals in residual fuel oil. AP-42, Volume I, Fifth Edition, Section 1.3.1, http://www.epa.gov/ttn/chief/ap42/] than do distillate fuel oils. The combination of these characteristics means that residual fuel oil-fired boilers and process heaters have higher emissions of metal HAPs and PM than boilers and process heaters burning distillate fuel oils (light liquid fuels).

Residual fuel oils also have significantly different firing properties than do distillate fuel oils. The combustion characteristics of light and heavy liquids are different, because these fuels have very different flow/viscosity and atomization characteristics and different energy contents. Per API, typical residual fuel has about 7% more energy per gallon than a distillate fuel oil. As a result of these property differences, at a minimum, heavy fuel oil firing requires different burner tips then are needed when firing lighter fuel oils. The heating value and flame height differences between these fuels may also impose unit design and operating constraints.

In addition, residual fuel-fired boilers must operate a soot blowing cycle on a periodic basis to maintain their heat transfer efficiency, during which opacity and PM levels increase. While the liquids database does not appear to include any data characterizing soot blowing emissions, the proposed emission limits would apply during that time and thus these emissions must be considered. It is, therefore, clear that metal HAP and PM emissions at least, distinguish residual fuel-fired units from distillate-fired units. Indeed, EPA has recognized this fact by creating an implicit subcategory for residual-fuel fired units in the proposal by requiring in section 63.7525 that residual oil-fired process heaters and boilers (but not distillate units) install a PM CEMS.

Thus, from an equipment design and operations standpoint as well as an emissions standpoint, there is a clear distinction between boilers and process heaters firing light liquids versus those that fire heavy liquids. By splitting the liquid subcategory and applying work practice requirements to the new light liquids subcategory (as most emissions from these units are so low that they cannot be reliably measured), the Agency would provide incentives for sources to switch to light liquids where appropriate.

Response: See response to comments EPA-HQ-OAR-2002-0058-1869.1, excerpt 4 and EPA-HQ-OAR-2002-0058-3213.1, excerpt 159.

Subcategories: Natural Gas/Refinery Gas (Gas 1)

Commenter Name: William C. Herz
Commenter Affiliation: The Fertilizer Institute
Document Control Number: EPA-HQ-OAR-2002-0058-1910.1
Comment Excerpt Number: 3

Comment: TFI offers that, because emission limits are proposed in units of pounds per million British thermal units, there is no need to delineate subcategories of natural gas-fired boilers and process heater units. The same work practice standard that is proposed for the Gas 1 subcategory is equally effective for all natural gas-fired boilers and process heater units, regardless of heat input capacity. Heat input capacity does not significantly change the operation of boilers and process heater units, nor is there a difference in the characteristics of the natural gas used in these units. Further, the proposed rule does not provide any compliance and monitoring requirements for those natural gas-fired boilers and process heater units with heat input capacity between 10 and 100 MMBtu/h.
TFI requests that EPA require all natural gas-fired boilers and process heater units adhere to the same work practice standard. If EPA determines that it will not subject all natural gas-fired boilers and process heater units to the same work practice standard, TFI requests that the Agency redefine the Gas 1 subcategory to include all natural gas-fired boilers and process heater units having a heat input capacity less than 100 MMBtu/h.

Response: EPA acknowledges the comment and agrees that separate standards are unecessary for gas-fired boilers versus process heaters.

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council
Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 2

Comment: EPA justifies its subcategories for boilers burning at least 90 percent natural gas/refinery gas, and for metal process heaters essentially on cost and policy grounds, neither of which is a lawful basis for setting subcategories under section 112(d). It is notable, at the outset, that these subcategories include over 11,000 of the 13,555 boilers EPA identifies as the universe of regulated major source industrial boilers. For these boilers and process heaters, EPA first states that setting separate subcategories would assure that they are subject to emissions standards on the basis of their emissions characteristics. 75 Fed. Reg. 32,017. The natural gas/refinery gas subcategory, the Agency asserts, is necessary to ensure standards based on "the best performing units with similar design and operation," id., even though what the Agency actually does is to propose a work process standard for this subcategory (which as shown below is further unlawfully supported entirely on the policy grounds that it will incent fuel-switching to gas).

Response: EPA has revised the definition of natural gas, consistent with the boiler NSPS definition. Any other gaseous fuels other than natural gas or refinery gas must demonstrate that they are at or below the specifications in the final rule for mercury and hydrogen sulfide. See preamble for discussion of gas specification. The 48-hour allowance or period of gas curtailment/gas supply emergencies applies to any liquid fuel, so any gas 1 boiler firing compareable liquid fuels for periodic testing or during allowable periods could still qualify as a gas 1 boiler.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 30

Comment: EPA should expand the Gas 1 subcategory to also include other gases that, like natural gas and refinery gas (we also note that there is no definition for refinery gas in the proposed rule), are expected to contain little to no "fuel dependent HAP" such as mercury, heavy metals, and chlorine. For example, process gases generated by chemical manufacturing processes would be similar to refinery gases. Eastman has several such process gas streams which we believe pose no different issues than natural gas or refinery gas when combusted. These gas streams are all different mixtures of hydrogen, nitrogen, carbon dioxide, carbon monoxide and a variety of hydrocarbons including methane, ethane, ethylene, and propane. Chlorine is not expected in any of these streams over 5 ppmv and no heavy metals are known to be present. The lowest heating value of these streams is 325 Btu/scf and several of the streams contain significant amounts of hydrogen. These streams are all burned in highly efficient combustion devices.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1

Comment Excerpt Number: 31

Comment: If EPA is concerned that some process gases are of lower value and may not burn well, we suggest that EPA set some thresholds for heating value and/or hydrogen content similar to what was done for the NSPS flare criteria (see 40 CFR 60.18(b)). Here, gases burned in non-assisted flares must have either a minimum hydrogen content of 8 percent or a minimum heating value of 200 Btu/scf.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group
Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 56

Comment: Given the importance of landfill gas and the fact that landfill gas can be processed to the extent that it is like natural gas (and even injected into natural gas pipelines), the Auto Group recommends that EPA add a component to the definition of “natural gas” that would include landfill gas, i.e., a fourth component to the definition that would say “any landfill gas that is processed and transported through a dedicated pipeline.” “Landfill gas” also could be defined as “gas derived from the decomposition of waste in a landfill.” [Footnote: See BAAQMD, Regulation 9, Rule 7.] This would ensure that landfill gas units are treated similarly to natural gas units given these fuels can be found in the same distribution system.

Response: See response to comments EPA-HQ-OAR-2002-0058-2761.1, excerpt 15 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 73 for the definition of natural gas needs to be broader to account for non-geological origins of natural gas.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 167

Comment: It is not possible for EPA to subcategorize further on the basis of design characteristics and then apply the floor methodologies in section 112(d)(3) to derive numerical emission limits for each appropriate subgrouping of Gas 1 units. The Gas 1 database lacks sufficient information on design characteristics to allow rational sub-grouping of all of the Gas 1 units. In addition, the database lacks sufficiently robust emissions data to allow the calculation of floors for each of the resulting subgroups. As we have discussed elsewhere, we do not feel the database information is even adequate for allowing emission limits to be calculated for the subcategories recommended in the proposal, much less for subcategories of those subcategories.

Response: See response to comment EPA-HQ-OAR-2002-0058-2690.1, excerpt 41 for dataset inadequacies.

Comment Excerpt Number: 172

Comment: The characteristics of refinery gas and other gases such as petrochemical gas are extremely similar, which supports the inclusion of petrochemical gas into the Gas 1 category with natural gas and refinery fuel gas. These gases are clean burning fuels and are composed mainly of methane, ethane, and hydrogen.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 32

Comment: To our knowledge, it does not appear that EPA has gathered information to justify placing chemical process gases in a separate subcategory from natural gas and refinery gas. Information on composition and heating value was not requested in the Phase I ICR survey.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Michael Palazzolo
Commenter Affiliation: Alcoa Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2967.1
Comment Excerpt Number: 7

Comment: Alcoa believes that the 10 percent limitation for oil usage in boilers and heaters designed to burn gas and oil is too restrictive. These units primarily burn gas. However, operators need the flexibility to burn oil for time periods when gas is not unavailable or too costly. Restricting the ability to burn oil in these units without controls will drive owners/operators away from the use of cleaner fuels. We recommend that EPA revise the definition for Unit designed to burn gas to allow 80 percent of annual heat input from gas rather than 10 percent.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Commenter Name: Donald R. Schregardus
Commenter Affiliation: Department of Defense
Document Control Number: EPA-HQ-OAR-2002-0058-2763.1
Comment Excerpt Number: 2

Comment: The final rule should clarify that the definition of Natural Gas as Liquid Petroleum Gas (§63.7575) includes all acceptable classes of propane.

Propane that meets the specification of ASTM D1835-03a is typically vehicle fuel grade or special-duty propane. There are other specification types of propane that should be acceptable under this regulation (e.g., the Gas Processors Association (GPA) Standard 2140-92.)

Revise the definition of natural gas in §63.7575 as follows:
Natural gas means:

(1) A naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or

(2) Liquid petroleum gas, as defined by the American Society for Testing and Materials in ASTM D1835-03a, -Standard Specification, for Liquid Petroleum Gases" (incorporated by reference, see §63.14(b)) or equivalent specification.

Response: See response to comment EPA-HQ-OAR-2002-0058-2849.1, excerpt 12 for Gas 1 subcategory and propane fired boilers.

Comment: The Gas 1 definition excludes several fuels (e.g., biogas, process offgases without metals) that would have combustion product profiles very similar to natural gas. Biogas generated as offgas from an aerobic wastewater treatment system range between 30% and 60% methane with the bulk of the remainder being carbon dioxide. The composition of these offgases contains minimal impurities and no metals. The burning characteristics would be very comparable to natural gas or refinery gas.

Based on the same rationale applicable to natural gas, INVISTA recommends that the definition of Gas 1 units be modified to allow for the combustion of biogas from wastewater treatment facilities.

Recommended Text at 63.75491(h): Unit designed to burn gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas and/or process off-gases with metals and sulfur content equal to or less than those in natural gas....

Response: EPA has revised the definition of natural gas, consistent with the boiler NSPS definition. Any unit burning any other gaseous fuels other than natural gas or refinery gas must demonstrate that the gases meet the specifications for mercury and H2S content.

Comment: If natural gas is chosen as a primary boiler fuel to avoid the excessively high cost or inability to meet the Boiler MACT emission limitations for liquid fuel-fired units, propane is the only backup fuel that is not subject to additional emissions controls. Local storage of propane is more expensive than for other backup fuels. Supplies of propane for delivery are often unreliable, particularly in times of greatest demand and in the quantities that would be required daily at the NGSB shipyard. Although other fuels may be technically viable, such as light distillate or biodiesel blends, if they were to constitute 10 percent or more of a boiler's annual consumption, the boilers would become subject to the full emissions limitations for liquid fuel-fired units. As explained above, the resulting baghouses, electrostatic precipitators, scrubbers, and other add-on controls make those options either financially burdensome or nonviable, which leads to the potential for significant manufacturing downtime during periods of gaseous fuel shortages.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment Excerpt Number: 41

Comment: The EPA database is not representative of gas- or liquid-fired boiler and process heater subcategories and is inadequate to determine if further or different subcategorization is needed to meet the need for the rule to be rational and achievable. The database does not include a reasonable collection of different designs and fuels. Nothing indicates that even the most basic range of unit types are represented in the data. For instance, firebox temperature is a critical parameter for process heaters in establishing their combustion characteristics and, thus, their emissions, but nothing in the database indicates a representative range of firebox temperatures, which can differ by as much as 600 degree F among process heaters, is included. Since firebox temperature is a critical part of a process heater‘s design duty, it cannot be changed for emissions control purposes since that would make it unable to serve its process duty. Similarly, it is not even clear how many and what size burners are installed for each unit, whether the unit has NOx controls, or whether the unit is natural draft or forced draft.

Response: EPA is not finalizing emisison limits for gas 1 units and therefore disagrees with further subcategorizing the gas 1 subcategory. See the preamble for how EPA has modified CO limits in the final rule.

Comment: The database also may be biased because it is not clear that it reflects the appropriate ration of boilers to process heaters. For refinery and petrochemical operations, which represent a significant proportion of Gas 1 and Gas 2 boilers and process heaters, there are many more process heaters in the source category than boilers. However, the database contains only somewhat more process heaters than boilers. This is significant because boilers typically are designed differently than process heaters, operate differently, have historically been regulated differently and typically have higher heat duties, more heat integration and generally are located in less congested areas than are process heaters. Additionally, boilers all operate in a fairly narrow range of firebox temperatures, while process heaters are designed for a very wide range of firebox temperatures, depending on the process need, resulting in a much broader range of emissions from process heaters than from boilers. As a result, the database may be biased towards boilers and, thus, may not accurately represent the source category.

Response: See response to comments EPA-HQ-OAR-2002-0058-2761.1, excerpt 15 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 73 for the definition of natural gas needs to be broader to account for non-geological origins of natural gas.

Comment: It is also important to realize that many of the Gas 2 streams are the same gases that make-up the Gas 1 subcategory. For instance, refinery gas often includes PSA gas (hydrogen), petrochemical gas, remediation gas, terminal gas, and/or marine gases if those operations are located in or near a refinery. In many cases, refineries and contiguous chemical, terminal and other operations have joint fuel gas systems. Requiring such operations to segregate the existing systems in order to avoid Gas 2 emission limitations for the refinery equipment will result in non-optimum fuel use and reduced energy efficiency. It will also lead to increased SO2 emissions because some Gas 2 gases that are currently being treated to remove H2S in order to meet refinery H2S limits will not be treated when they are no longer mixed with refinery fuel gas. Similarly, some Gas 2 streams that are now mixed with Gas 1 streams will be destroyed without beneficial heat recovery, in order to avoid the proposed Gas 2 emission limits for boilers and process heaters that fire more than 10% Gas 2, but are not primarily in Gas 2 service.

As discussed in Attachment B, it is clear that Gas 2 streams from most operations and refinery gas have similar compositions and combustion properties (e.g., heating values, Wobbe indices and adiabatic flame temperatures). That is, they are primarily composed of light hydrocarbons, such as methane and ethane, and hydrogen. This must be the case in order for the gas to have adequate heat content and to avoid liquid condensation and because higher molecular weight species are commercially valuable and thus would typically be recovered if they were present in large quantities. For all of these reasons, it is illogical to treat those gases differently (i.e., have them in a different subcategory) just because they occur in a different physical location.

Gas 2 fuels include process gas from chemical plants, landfill gas, digester gas, blast furnace gas, coke oven gas, and PSA gas. However, in the emissions information presented for the Gas 2 sources, most of the 74 sources listed, including all 9 in the floor calculation, appear to be located at chemical plants. Chemical plant process gas and PSA gas are typically very similar in composition to refinery gas and often are components of refinery gas. Thus, the data EPA has on the Gas 2 category is primarily from sources that would be considered Gas 1, except for the location at which they are generated.

Logic would seem to indicate that, at a minimum, chemical plant process gas and PSA gas should be grouped with refinery gas in the Gas 1 category. One solution for the remaining fuels in the Gas 2 category would be to establish a new floor. A better solution would be to combine all gaseous fuels into a single category with a work practice compliance requirement.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: B. EPA should allow other gases to be considered Gas 1.
Other gases that fall within the Gas 2 subcategory should be able to fall under the Gas 1 subcategory if certain criteria are met. For example, thresholds could be set related to minimum HHV, whether combustion of a gaseous stream is self-sustaining, percent composition, or maximum contaminant levels. If a gas other than natural gas/refinery gas meets the criteria, then it should be subject to the same work practice standards and included in the Gas 1 subcategory. There is very little difference between the emissions from top performers in the Gas 2 subcategory as compared to the Gas 1 subcategory; therefore, EPA should simply create one gas-fired subcategory.

Chemical process off-gas is an example that should be treated as Gas 1 with a work practice standard. CIBO believes that process off-gases derived from natural gas or petrochemical feedstocks that have low heating values due to their hydrogen content also provide useful combustion energy and should be treated similarly to Gas 1 units. These process gases provide stable combustion characteristics and typically have low contaminant content due to the nature of the processes. The EPA hydrogen fueled flare document- Basis and Purpose Document on Specifications For Hydrogen-Fueled Flares, Emission Standards Division, U.S. Environmental Protection Agency Office of Air Radiation, Office of Air Quality Planning Standards, March 1998, documents the basis for establishing minimum hydrogen content for unsupported flare combustion. The testing documented established the minimum hydrogen content of 8% by volume as that proven adequate for sustained combustion without support fuel (nonassisted flare operation).

As noted in the document, hydrogen has a lower heat content than organics commonly combusted in flares meeting the prior existing flare specifications and cannot, therefore, be used to satisfy prior control requirements. However, since the combustion of hydrogen is different than the combustion of organics, and the test report demonstrates a destruction efficiency greater than 98 percent, the EPA believes that hydrogen-fueled flares meeting the recommended specifications will achieve a control efficiency of 98 percent or greater. This level of control is equivalent to the level of control achieved by flares meeting the prior existing specifications. In addition to achieving the same destruction efficiency of VOC or organic HAP, these recommended specifications have the added advantage of reducing the formation of secondary pollutants; since the combustion of supplemental fuel would not be required by hydrogen-fueled flares to meet the existing flare specifications.

In another example, EPA does not have enough data on combustion of anaerobic digester gas to differentiate it from natural gas. As such, classification of anaerobic digester gas as Gas 2 is unreasonable. The use of digester gas is being promoted as a way of preventing emissions of potent methane GHGs from wastewater treatment plants, to minimize sludge production and as a way to conserve natural gas usage. The use of digester gas would not be expected to cause an increase in any HAPs. Any potential increase in SO2 emissions is readily controlled by conventional means. If digester gas combustion causes a unit to be regulated under Gas 2, the gas will likely not be burned in boilers or process heaters and will instead be flared resulting in an increase in fuel usage and emissions.

Therefore, CIBO recommends a similar approach be used to establish 8% by volume as a minimum hydrogen content in hydrogen fueled process gases as a criterion that allows its use as a fuel in boilers and process heaters under the Boiler MACT rule and allow consideration as Gas 1 with a work practice MACT approach.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: D. Inconsistencies Relative to use of Landfill Gas.
The Proposed Rule includes the definition of units designed to burn gas 2 as follows:

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that burns gaseous fuels other than natural gas and/or refinery gas not combined with any solid or liquid fuels.

Therefore, per this definition, a boiler or process heater firing any percentage of heat input of landfill gas (LFG) would be considered as a gas 2 unit and subject to all Proposed Rule requirements for gas 2, including the emission limits. These onerous requirements are basically at odds with the intentions of the EPA Landfill Methane Outreach Program (LMOP). As stated on the EPA web site:

The U.S. Environmental Protection Agency’s Landfill Methane Outreach Program (LMOP) is a voluntary assistance program that helps to reduce methane emissions from landfills by encouraging the recovery and beneficial use of landfill gas (LFG) as an energy resource. LFG contains methane, a potent greenhouse gas that can be captured and used to fuel power plants, manufacturing facilities, vehicles, homes, and more. (Reference: http://www.epa.gov/lmop/)

Many facilities with affected sources under this rule have implemented projects to burn LFG in boilers and process heaters, some in concert with the EPA LMOP program. While the actual analysis of LFG may vary over time and between landfills, the general composition is well known by EPA to contain methane, CO_2, nitrogen, hydrogen, argon/oxygen, and other trace constituents with a HHV of around 500 Btu/scf. HAP emissions from LFG combustion are not known to be a problem, and in fact, the top performing gas 2 unit for mercury one of the top performing units for D/F was the BMW watertube boiler firing LFG. There is no assurance that other units combusting LFG can achieve those limits due to landfill and combustion unit variability. In addition, the gas 2 emission limits also include an unrealistically low CO limit of 1ppmvd @ 3%O2 that likely cannot be achieved by any boiler or process heater firing any percentage of LFG. For example, one CIBO member package boiler demonstrated CO emissions when firing 27% LFG with natural gas that were more than 2.5x that seen when firing natural gas alone (55 ppm vs 21 ppm both at 3%O2), with a 20% reduction in NOx emissions with the LFG. It is likely that other units would see similar impacts on CO with combustion of LFG. Imposition of the proposed emission limits on units firing LFG will very likely result in a cessation of beneficial burning of LFG in boilers and process heaters for two reasons: first, and most importantly, there is no assurance that all emission limits can be achieved even with application of emissions control technology; and second, installation of emissions controls in an attempt to meet the proposed limits will be prohibitively expensive compared to simply stopping combustion of LFG and instead increase use of natural gas. Thus this Proposed Rule will stop the LMOP program in its tracks relative to use of LFG as boiler and process heater fuel; result in increased criteria pollutant emissions; and result in increased GHG emissions due to flaring of the LFG and alternative use of increased natural gas. CIBO instead recommends that EPA recognize the environmental benefits of using LFG and treat LFG as gas 1 with use of a work practice approach.

Response: EPA has revised the definition of natural gas, which includes some treated landfill gases with a methane content of at least 70 percent. For other landfill gas fuels, if the LFG is demonstrated to fall below the gas specifications, as discussed in the final rule, the boiler can qualify for a work practice standard.

Comment: HAP Formation and Emissions from Gas Combustion
Gaseous fuels used in industrial processes typically contain a range of different hydrocarbons and/or hydrogen. Pipeline natural gas consists primarily of methane, with smaller amounts of ethane and other saturated hydrocarbons up to C5 or C6 (Table 1). Refinery fuel gases also consist primarily of methane, with smaller amounts of both saturated and unsaturated hydrocarbons, but also may contain significant amounts of hydrogen (Figure 1). Petrochemical process gas fuels typically have a similar range of compositions.
HAP emissions from gas-fired combustion generally arise from:
Fuel contaminants such as particles, mercury and chlorine compounds;
Combustion conditions that produce particles and organic compounds;
Contaminants in the combustion air such as particles, mercury and chlorine compounds.
Contaminants in other streams that may be introduced to the boiler or process heater gas

path such as vent gas streams, NOX control reagents (e.g. ammonia, urea), or water. Elements in the fuel such as mercury and chlorine are potential sources of mercury and hydrogen chloride (HCl) in the combustion products, to the degree they pass through the system. Mercury is highly mobile due to its volatility. The presence of mercury in unprocessed natural gas varies considerably among regional sources. Mercury produces undesirable effects in natural gas processing equipment, and is typically removed in carbon beds before processing or with condensates before distribution to sales pipelines. Thus, the concentration of mercury in processed natural gas delivered to the pipeline is typically much lower than the raw produced gas.

A survey of processed natural gas from 19 different fields in the US showed that mercury was undetected in 15 samples at detection limits of 0.012 lb/trillion Btu and in 3 samples at detection limits of 0.0012 lb/trillion Btu (GRI, 1994). Mercury was detected in only a single sample at 0.0012 lb/trillion Btu, just above the detection limit. Halocarbons (including chlorinated compounds) were undetectable in all samples at a detection limit of 0.1 ppmv.

GRI and EPRI tested two gas-fired utility boilers and found mercury undetectable in the stack at detection limits of 0.34 and 0.35 lb/trillion Btu (GRI, 1995). They did not measure HCl or dioxins/furans (D/F). Carbon monoxide (CO) ranged from 0.06 to 0.3 lb/MMBtu over a range of loads and operating conditions. CO detection limits were reported as 0.0037 and 0.00073 lb/MMBtu. PM was not measured. Total hydrocarbons (THC), as methane, ranged from 5 to 20 lb/trillion Btu. Mercury was detected in one fuel gas sample at 0.0013 lb/trillion Btu. Mercury was not detected in two natural gas samples in gas turbine tests at detection limits of 0.0006 lb/trillion Btu.

Contaminants in the combustion air also are a potential source of stack emissions. The upper end of the range of HCl and dioxins/furans toxic equivalent (TEQ) concentrations measured in ambient air are comparable to the proposed emission limits proposed for Gas 2 fuels (Table 2). Concentrations of mercury and particulate matter are considerably below the proposed emission limits for either gas fuel subcategories, while CO concentrations are similar. This suggests that the combustion air in gas-fired combustion systems potentially contributes to measured CO, hydrogen chloride (HCl) and dioxins/furans TEQ emissions, and that stack emissions may be difficult to differentiate from ambient background levels at the proposed emission limit concentrations.

Volatile and semi-volatile organic HAPs (O-HAPs) are thought to be formed in flames via various chemical pathways that form volatile, aromatic and polycyclic compounds (e.g., Marinov et al., 1996 and others). Under normal combustion conditions, these compounds are also destroyed but trace amounts may escape complete combustion. Pilot-scale combustion tests under well-controlled conditions shows that gaseous hydrocarbons tend to burn very cleanly regardless of the distribution of individual lighter (C1-C6) hydrocarbons within a blend, over a fairly wide range of operating conditions and temperatures (Seebold, 1997; England et al., 2001). Gas fuel blends spiked with olefinic and aliphatic components also produced similar (very low) levels of O-HAP emissions under normal combustion conditions (ibid.). Comparison of pilot-scale and earlier field data for different gas fuel compositions also shows that O-HAP emissions are similar among fuels ranging in heating value from approximately 600 to 1800 Btu/scf (ibid.).

The absence of a measurable difference in O-HAP emissions for such a wide range of fuel compositions strongly suggests that if combustion conditions are maintained within normal bounds that O-HAP emissions are not significantly affected by fuel composition.

Response: EPA recognizes that mercury content of natural gas can vary. Some natural gas is drilled locally with slight differences depending on the geographic location while other natural gas is imported and stored as LNG. Based on data available from Calgon corporation we have identified the range of mercury content of natural gas in North Amercia and established a maximum mercury specification for any gas fuel that can qualify as a gas 1 fuel using the maximum mercury content of the reported mercury ranges.

Comment Excerpt Number: 260

Comment: The Gas 1 CO data also offer little insight into which controls are associated with lower CO emissions (Figure 2). The CO floor is populated largely by units with no controls, except for a few units primarily with low-NOX burners or selective catalytic reduction (SCR) systems for NOX emission control. There are four units with oxidation catalysts, none of which are in the floor. CO for these units ranges from slightly below 1 ppm to nearly 10 ppm. There are data in the ICR database for two additional units with oxidation catalysts that EPA did not use due to emission unit conversion problems. An approximate conversion was made for this discussion (Figure 3), showing even higher CO emissions for these two units assuming the approximate conversion is valid. There are a number of units with FGR for NOX control. These units populate the higher end of the CO range with most units between approximately 10 and 100 ppm. This is expected as discussed above. There are many units with low-NOX burners, some also with FGR. Reported CO emissions from these units range from 0.1 to a few hundred ppm, with most units populating the upper middle range of the population, which also is expected. Low-NOX gas burners achieve NOX reduction via staged combustion to achieve lower temperatures and delayed mixing and/or (fuel-lean) premixing of the fuel and air. This creates conditions that are more challenging for CO burnout, and elevated CO is often a result. There are a few units with water or steam injection for NOX control, which have among the highest CO emissions from approximately 20 to a few hundred ppm. Depending on design, water or steam injection can be an effective, low capital cost NOX control solution but elevated CO emissions are a common consequence of the rapid quench that occurs in the vicinity of the injectors. SCR may potentially have some impact on CO via catalytic oxidation, although this is speculative. Three near-identical units firing the same fuel at one facility have SCR and a wet electrostatic precipitator (ESP) and are jet fuel capable but fired refinery gas during the reported tests. One unit is in the floor, one unit has CO approximately 1 order of magnitude higher and the third unit has CO approximately 3 orders of magnitude higher. There are several units with SCR alone. Most of the units have CO emissions between 1 and 30 ppm, with three units below 1 ppm. There is no beneficial effect of SCR on CO evident in the data.

Response: EPA did not rank and analyze emissions in each subcategory according to the control devices installed but instead ranked the units based on the emissions measured. EPA is not finalizing CO emission limits for gas 1 units.

Comment: The Gas 1 data set is much larger, encompassing data for hundreds of units. Nearly all the data are survey data from Phase I of the ICR. Most units are reported to have no emission controls. The data encompass a number of units with a variety of emission controls, primarily technologies for NOx emissions control and four units with oxidation catalyst for CO control. A few units are reported to have cyclones, ESPs and other particulate matter control devices although it‘s not clear why they would have needed these when firing natural gas or refinery gas these should be further investigated to determine if they are appropriately characterized. Examining the filterable PM emissions data for different technologies shows there is no clear trend suggesting an effective emission control technology for Gas 1 units (Figure 5). The data for each technology span a wide range of PM emissions and no technologies dominate the lower range of reported emission data. Thus, there is little insight offered by the ICR data with respect to effective filterable PM control technologies for gas-fired units.

Response: See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 260 for HAP emission control devices installed on Gas 1 units.

Comment: The proposed regulations do state that "Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year are not included..." in the Oil ICI Boiler category. The 48 hour limit is too restrictive for the dual fuel-fired boilers in that the 48 hours equates to only approximately 0.5% of operating hours on an annual basis and only if the one of the stated conditions existed. For consistency purposes, the ICI MACT rule should use the same definition for oil and gas fired boilers as is used in Part 75 of the Acid Rain regulations. This would allow a three-year average of at least 90 percent heat input from gas-firing with no individual year less than 85%.

Response: See response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 223 for the 48 hour a year provision.
See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment: EPA Should Include Petrochemical and Chemical Plant Off-Gas Streams in the Gas 1 Subcategory because The Use of Petrochemical and Chemical Plant Off-Gas Streams as Fuel is Essential to Promote Energy Efficiency and the Composition of these Gas Streams is Similar to Natural Gas and Refinery Gas. Large integrated chemical plant sites strive to be as energy efficient as possible. One way to promote energy efficiency is to capture off-gas from petrochemical and chemical plant off-gas streams and re-use these streams as fuel in a variety of combustion sources. Typically these off-gas streams are blended with natural gas and then used in combustion sources at the plant sites. One of the largest off-gas streams is the fuel produced from on-site ethylene production plants. The ethylene process off-gas is very similar in composition to natural gas and refinery gas. This off-gas stream is a very clean fuel and a typical composition is shown in the table below. The main difference is that this stream contains a significant amount of hydrogen which is a very clean fuel to use.

Column A represents a natural gas stream and Column B represents a typical ethylene process off-gas stream from an ethylene production plant. [See submittal for un-numbered, un-named table.]

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: Landfill Gas

Another case of gases currently considered as Gas 2 that should be treated similarly to Gas 1 with a work practice is landfill gas combustion in boilers and process heaters. The proposed rule highlights inconsistencies within EPA relative to use of Landfill Gas (LFG).

A boiler or process heater firing any percentage of heat input of LFG would be considered as a Gas 2 unit and subject to all proposed rule requirements for Gas 2, including the emission limits. These onerous requirements are basically at odds with the intentions of the EPA Landfill Methane Outreach Program (LMOP). As stated on the EPA web site: The U.S. Environmental Protection Agency's Landfill Methane Outreach Program (LMOP) is a voluntary assistance program that helps to reduce methane emissions from landfills by encouraging the recovery and beneficial use of landfill gas (LFG) as an energy resource. LFG contains methane, a potent greenhouse gas that can be captured and used to fuel power plants, manufacturing facilities, vehicles, homes, and more. (Reference: http://www.epa.gov/lmop/)

Many facilities with affected sources under this rule have implemented projects to burn LFG in boilers and process heaters, some in concert with the EPA LMOP program. While the actual analysis of LFG may vary over time and between landfills, the general composition is well known by EPA to contain methane, CO_2, nitrogen, hydrogen, argon/oxygen, and other trace constituents with a HHV of around 500 Btu/scf. HAP emissions from LFG combustion are not known to be a problem, and in fact, the top performing Gas 2 unit for mercury and one of the top performing units for D/F was the BMW watertube boiler firing LFG. There is no assurance that other units combusting LFG can achieve those limits due to landfill materials/LFG and combustion unit variability.

Response: See response to comments EPA-HQ-OAR-2002-0058-2761.1, excerpt 15 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 73 for the definition of natural gas needs to be broader to account for non-geological origins of natural gas.

Comment: Refinery Gas vs. Petrochemical Off-Gas Streams: The Proposed Rules provide special provisions for Refinery Gas combustion sources, which does not appear to include Petrochemical Off-Gas Streams. We think the Petrochemical Off-Gas Streams (with non-halogenated hydrocarbons) should be afforded the same regulatory accommodations as refinery gas. An excellent example of Petrochemical Off-Gas Streams that should be afforded this accommodation is ethylene plant process fuel gas, which is primarily hydrogen and methane, and is an ideal fuel source.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: EPA Should Modify the Definition of "Unit Designed to Burn Gas 1 (NG/RG) Subcategory." Section 63.7575 of EPA's proposed rule defines "Unit designed to burn gas 1 (NG/RG) subcategory" as "includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average." In the memorandum "Development of Baseline Emission Factors for Boilers and Process Heaters at Commercial, Industrial, and Institutional Facilities" dated April 2010 from Amanda Singleton and Graham Gibson, ERG to Jim Eddinger, U. S. EPA, OAQPS, the process is described for developing baseline emission factors. That process includes a step to categorize fuels combusted and control devices utilized. Then emissions data for each combustion unit was averaged and a unit-specific baseline emission factor assigned.

Fuels listed in the 2008 Questionnaire for Boilers, Process Heaters, Incinerators and Other Combustion Units (ICR No. 2286.01, OMB Control No. 2060-0616, EPA Form No. 5900-122) were categorized into one of 11 fuel categories listed in Table 2 which ultimately ended up in the 11 subcategories defined in the proposed rule. Specific fuel types were mapped to the categories using Table B.1 of Appendix B.

From Table B.1 the fuel category "Natural Gas & Other Non-Process Gases" lists Hydrogen, LPG, Natural Gas, Pilot Gas, Propane, and Refinery Gas. This category appears to be the source category used in MACT floor analyses resulting in the subcategory defined above. From the fuel type mapping it is seen that this category contains non-process fuels besides natural gas and refinery gas. The subcategory "Unit designed to burn gas 1 (NG/RG)" includes hydrogen, LPG, and propane." In addition to the EPA MACT floor analysis conducted by EPA that included these fuels in that subcategory, it is evident that such fuels would not include the five grouped HAPs for boilers or process heaters: mercury, non-mercury metallic HAP, inorganic HAP, non-dioxin organic HAP, and D/F.

Modifying the definition as proposed below enhances user understanding of the subcategory while remaining consistent with the MACT floor analysis. Thus, Dow proposes the following revised definitions for inclusion into the final rule:

Unit Designed to Burn Gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas or off-gas streams from petrochemical and chemical plant processes on a heat input basis on an annual average.

In conjunction with the definition of "Unit Designed to Burn Gas 1 (NG/RG), Dow suggests the following definition to add to the regulatory text in Section 63.7575:

Refinery Gas and Off-Gas Streams from Petrochemical and Chemical Plant processes - means "a gaseous mixture of methane, light hydrocarbons, hydrogen, and other miscellaneous species (nitrogen, carbon dioxide, hydrogen sulfide, etc.) in the refining of crude oil or in the production of chemicals or petrochemicals and that is separated for use as a fuel in boilers and process heaters throughout the site.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: ACC also conducted a review of the data used to develop the Gas 2 category CO limits. Gas 2 fuels may include: process gas from a chemical plant, landfill gas, digester gas, blast furnace gas, coke oven gas, or PSA gas. However, most of the 74 Gas 2 sources, , including all 9 in the floor calculation, appear to be located at chemical plants. Chemical plant "process gas" is typically similar in composition to refinery gas, whereas the other Gas 2 fuel types (landfill, coke oven, etc.) generally have much greater variability in their composition. This variability makes it more difficult to control the combustion airflow, and therefore, CO emissions. As such, chemical plant process gas is not representative of the "other gaseous fuel" units, yet it has been used exclusively to set the CO floor for Gas 2.

We believe that chemical plant process gas should be grouped with refinery gas in the Gas1 category. In so doing, EPA should establish a new floor for the remaining fuels in the Gas 2 category so that the standards are representative of and based on the composition of those gases (note that the average CO emissions of the 74 units in the Gas 2 data set, including all the chemical plant process gas units, is over 150 ppm CO). A better solution would be to combine all gaseous fuels into a single category, with a work practice compliance requirement.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: Clarify the Definition of "Unit Designed to Burn Oil" Subcategory to Avoid Overlap with the "Unit Designed to Burn Gas 1 (NG/RG)" Subcategory. A boiler or process heater that meets the currently proposed definition of a "unit designed to burn gas 1 (NG/RG) subcategory" could also meet the proposed definition for a "unit designed to burn oil subcategory" if, for example, it burns liquid fuel for periodic testing exceeding a combined total of 48 hours during any calendar year, but not exceeding 10 percent (heat input basis) on an annual average. We request that the oil subcategory definition in proposed section 63.7575 be changed as follows: "Unit designed to burn oil subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent solid fuel on a heat input basis on an annual average, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that meet the definition for the "unit designed to burn gas 1 (NG/RG) subcategory" burn liquid fuel during periods of gac curtailment, gas supply emergencies or for periodic testing ,9-f liquid fuel not to exceed a are not included in this definition."

Response: See response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 223 for the 48 hour a year provision.

Commenter Name: Sarah E. Amick
Commenter Affiliation: Rubber Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 1

Comment: Rubber Manufacturers Association (RMA) tire manufacturer member companies own and operate 56 major source boilers, at 17 facilities in 13 states[8 Major source boilers at RMA member tire manufacturing facilities are located in the following states: Alabama, Arkansas, Illinois, Indiana, Kansas, Kentucky, Mississippi, North Carolina, Ohio, Oklahoma, South Carolina, Tennessee and Virginia] that would be impacted by the proposed rule. These boilers range in size from 19 MMBtu/ hr to 190 MMBtu/hr and combust either natural gas or a combination of natural gas and light liquid fuel oils. Under the proposed Boiler MACT rule, boilers burning greater than 10% liquid fuel are classified as liquid fuel boilers. We believe the fuel category thresholds are too low and should not be based on the design fuel. RMA recommends that EPA classify boilers based on predominant use of a particular fuel, where predominant use is defined as over 50% of the fuel use, excluding fuel used during periods of curtailment.

Requiring boilers that periodically burn more than 10% liquid fuel (per year) to preserve the ability to burn liquid fuel by installing costly add-on controls that may rarely be used seems counter productive. Again, categorizing boilers based on predominant use would alleviate the burned of installing add-on controls for boilers that predominantly combust natural gas.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Document Control Number: EPA-HQ-OAR-2002-0058-2843.1
Comment Excerpt Number: 1

Comment: EPA is defining a gas boiler as one that burns at least 90% gas and 10% any other fuel. We are comfortable with this definition. However, this definition further states that if a gas boiler burns another fuel for more than 48 hours in a year due to a natural gas emergency, this boiler then becomes categorized as a liquid gas boiler. This has the potential of being a major problem. SCA has an agreement with our natural gas provider to be curtailed in unique cases. For instance, if temperatures in Wisconsin get very cold, and demand for natural gas spikes, SCA will defer getting our natural gas so that a sufficient supply is available to hospitals, schools and homes. During these times, SCA would switch to oil until the curtailment ends. Under the new rules, if this curtailment — which clearly benefits the common good of the region — were to extend past 48 hours in a year, SCA could be classified by the EPA as a ‘liquid fuel’ burner and be subject to the many rules of this category.
There are other examples of this nature such as when SCA needs to periodically test our oil burners to ensure they are working properly or when we have to use up an aging oil supply before it becomes unusable.
We ask that the EPA keep the 90/10 standard but eliminate the extremely unrealistic 48 hour a year provision.

Response: See response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 223 for the 48 hour a year provision.

Commenter Name: Michael Potter
Commenter Affiliation: Goodyear Tire and Rubber Company
Document Control Number: EPA-HQ-OAR-2002-0058-3181
Comment Excerpt Number: 1

Comment: It is not clear to Goodyear whether the period of fuel oil usage reported under section 63.7545(f) is considered to be a deviation, or whether the fuel oil used during the curtailment or supply interruption period is to be included in the calculation of the 10 percent annual heat input specified in the definition of liquid fuel subcategory.

The proposed regulations should exclude backup fuel oil usage during routine periodic equipment checks and maintenance and periods of gas curtailment and supply interruption from the applicability determination for the liquid fuel subcategory.

The proposed Boiler MACT rules anticipate the possibility of gas curtailment and supply interruptions, but have not gone far enough to address such eventualities. The definition in proposed 40 CFR section 63.7575 for the liquid fuel subcategory provides that liquid fuel (i.e. oil) can provide up to 10 percent of the annual heat input to a boiler before the liquid fuel category applies. Boilers with backup oil capability must routinely burn some standby fuel on a periodic basis to assure that the backup fuel equipment is maintained properly and will be in good operating condition should a gas curtailment or supply interruption occur and combustion of backup fuel be needed. This routine periodic usage presumably must be counted toward the 10 percent allowance before the liquid fuel subcategory goes into effect.

In addition, it is impossible for a boiler owner/operator to predict how often or for how long a curtailment or interruption might occur. Even if EPA is properly notified of the use of oil during curtailment or interruption periods in accordance with 40 CFR section 63.7545(f), it is not evident that oil used during a curtailment or interruption period would be excluded from the 10 percent heat input allowed before the liquid fuel subcategory goes into effect.

If the routine periodic use of backup fuel oil for equipment checks and maintenance and use of backup fuel oil during extended periods of curtailment or interruption are counted toward the 10 percent heat input specified in the liquid fuel subcategory, that threshold can easily and unexpectedly be exceeded. To resolve this unreasonable situation, the proposed regulations should be revised to provide that uses of backup fuel oil for purposes of routine periodic equipment checks and maintenance, along with all fuel oil Usage during periods of actual gas curtailments and interruptions, are specifically excluded from counting toward the 10 percent heat input trigger for the liquid fuel category applicability.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment: EPA should also consider the following for all natural gas-fired boilers and process heaters:
Work practices for natural gas boilers and process heaters are appropriate in lieu of emission limits;
Given the very low-HAP emissions of natural gas-fired units, EPA should consider delisting these sources from regulation under CAA section 112(c)(9);
The proposed energy assessment is not supported by the statute and is not demonstrated as providing any HAP reduction;
EPA's definition of natural gas needs to be broader to account for non-geological origins of natural gas such as landfill gas, biogas, and synthetic gas derived from coal.

Response: See response to comments EPA-HQ-OAR-2002-0058-2761.1, excerpt 15 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 73 for the definition of natural gas needs to be broader to account for non-geological origins of natural gas.

Comment: Units that burn gas and <10% liquid on an annual basis would appear to be in both a "gas subcategory" and the "unit designed to burn oil subcategory." Furthermore, the proposed exclusion for gas-fired units that burn oil during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel from the liquid subcategory would appear to be unworkable as drafted because it appears to only allow oil firing for 48 hours a year. As experience has repeatedly shown, natural gas curtailments would likely almost always exceed 48 hours. We assume the 48 hours was meant to apply only to the testing situation, and the draft language does not accurately represent the Agency intent. To address these two issues, RMA recommends that EPA clarify that gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergencies are not included in the definition of "units designed to burn oil subcategory."

Response: See response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 223 for the 48 hour a year provision.

Document Control Number: EPA-HQ-OAR-2002-0058-2943.1
Comment Excerpt Number: 5

Comment: This definition is not inclusive enough to capture all of the situations where a unit primarily fired on natural gas might have to utilize its backup fuel oil. For example, many Title V permits require periodic opacity measurements to be performed while a unit is burning its backup fuel. Scheduling this during a period of gas curtailment would be nearly impossible, and a period of gas curtailment may not even occur within a compliance period. In addition, the

infrequency of operation of this equipment requires routine periodic testing while the unit fires backup fuel to ensure functionality.
One way to include these additional situations would be to expand the statement within the body to mimic or simply reference the definition of Gas-fired boiler found in 63.11237. "Gas-fired boiler includes any boiler that bums gaseous fuels not combined with any solid fuels, bums liquid fuel only during periods of gas curtailment, gas supply emergencies, or periodic testing on liquid fuel. Periodic testing of liquid fuel shall not exceed a combined total of 48 hours during any calendar year."

Comment: Additionally, PFI requests guidance and clarification on the following issues related to this definition. Is the intent to include the heat input of alternative fuel use during periods of natural gas curtailment or supply interruption, as defined under section 63.7575, toward the assessment of the annual average under the Gas 1 subcategory —Unfortunately, a facility operating under a curtailment contract with a natural gas supplier has no control over the frequency or duration of such events. Therefore, PFI believes that the alternative fuel use during such time periods should be excluded in the assessment of this subcategory determination.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

EPA has modified the 48-hour periodic testing and gas curtailment provision of the unit designed to burn liquid subcategories. If a unit is burning liquid fuels under either of these conditions these periods to not count towards the heat input threshold. In order to be a gas 1 unit the unit must only burn liquid fuels during these specific exempted periods, burning any other fuel could cause the unit to be part of another subcategory.

Commenter Name: Shelley Schneider
Commenter Affiliation: Nebraska Department of Environmental Quality
Document Control Number: EPA-HQ-OAR-2002-0058-2820.1
Comment Excerpt Number: 5

Comment: EPA includes in the Gas 2 subcategory gaseous fuels other than natural gas and/or refinery gas. The definition of natural gas is defined as "a naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or (2) Liquid petroleum gas..." Biogas does not meet the natural gas definition and is therefore included in the Gas 2 subcategory.

Sources within the Gas 2 subcategory are required to comply with numerical emission standards and conduct costly stack testing. The Gas 1 subcategory includes units burning 90% natural gas/refinery gas on an annual heat input basis. Units included in the Gas 1 subcategory are subject to less stringent work practice standards. NDEQ asks EPA to consider including biogas in the natural gas/refinery gas subcategory or at a minimum increasing the percentage of other gases allowed to be burned while still maintaining their Gas 1 status.

Response: See response to comments EPA-HQ-OAR-2002-0058-2761.1, excerpt 15 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 73 for the definition of natural gas needs to be broader to account for non-geological origins of natural gas.

Comment: Finally, we urge the Agency to clarify several uncertainties about which units are considered to be gas-fired under the major source rule, and what their notice obligations are. Gas-fired units predominate among our members' boilers, and some SOCMA members have dual-fuel units that can burn gas or oil. The differentiating point between oil and gas-fired units is thus of great importance to SOCMA members. But the proposal is inconsistent on this point.

The preamble declares that "the gas categories" comprise any unit that "burns gaseous fuel and less than 10 percent, on an annual average heat input basis, of liquid or solid fuel." SOCMA supports this characterization, which is consistent with the characterizations of coal, biomass and liquid-fired units that immediately precede it in the preamble.

However, the preambular characterization of gas-fired boilers is contradicted by the proposed regulatory definitions of gas and oil-fired units. One of those definitions also conflicts with the comparable definition in the proposed Area Source Boiler rule: "The definition of "Unit designed to burn gas 1" is consistent with the preamble: any unit "that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average" is a Gas 1 unit. Thus, a unit that burned 92% natural gas and 8% oil would be a Gas 1 unit."

But the definition of "Unit designed to burn gas 2 (other)" creates a conflict: It includes any unit "that burns gaseous fuels other than natural gas and/or refinery gas not combined with any solid or liquid fuels."5 Thus, a unit that burned 99% process gas and 1% oil would not qualify, and would presumably be a liquid-fired boiler.

Even more confusing, the definition of the “Unit designed to burn oil” subcategory includes units “that burn any liquid fuel.”6 Its only exemption is for “gaseous fuel boilers . . . that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year.” This would imply that a natural gas-fired boiler that burned oil 5% of the time, but not for reasons related to curtailment, emergency or testing, might qualify as a Gas l unit, but would also be considered an oil-fired unit.

Even more confusing, the foregoing 48 hour limitation, as expressed in the definition of “gas-fired boiler” contained in the proposed Area Source Boiler rule, is clearly limited only to periodic testing and does not apply to curtailment or supply emergency periods.

Even more confusing, proposed § 63.7445(f) requires a “natural gas-fired boiler” that intends to use a fuel other than natural gas “or equivalent” (presumably this means refinery gas – so why not just say a “Gas 1 unit”?) to give the permitting agency notice within 48 hours of any declaration of gas curtailment or supply emergency. By its terms, this notification does not extend to decisions to use other fuels for periodic testing or, indeed, for other reasons.

To resolve these inconsistencies, SOCMA urges EPA to revise the various regulatory definitions to simply track the preambular explanation quoted above.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment: The liquid fuel subcategory applicability should be based on predominant usage.

EPA has not properly explained the selection of 10 percent liquid usage as the threshold for application of the liquid fuel subcategory. Goodyear believes that fuel subcategories logically should be based on the fuel prevalently used in the boiler. The extremely high control costs that would be required to comply with liquid fuel subcategory standards cannot be justified for boilers that will use natural gas most (i.e. more than 50 percent) of the time. This is particularly true insofar as Goodyear is not certain that technology exists to reliably achieve the proposed liquid fuel subcategory standards in its existing boilers, regardless of cost. Therefore, Goodyear believes the definition for the liquid fuel subcategory should be based on a 50 percent annual heat input threshold rather than 10 percent.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment: Additionally, the definition of natural gas within the proposed NESHAP is inconsistent with the definition of natural gas found in 40 CFR Part 60 Subpart Db New Source Performance Standards (NSPS) for Industrial/Commercial/Institutional Steam Generating Units. The NSPS definition reads: 1) A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or (2) Liquefied petroleum gas, as defined by the American Society for Testing and Materials in ASTM D1835 (incorporated by reference, see §60.17); or (3) A mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 34 and 43 megajoules (MJ) per dry standard cubic meter (910 and 1,150 Btu per dry standard cubic foot). At a minimum, the natural gas definitions should be consistent across federal air regulations.

Response: EPA has revised the definition of natural gas, consistent with the boiler NSPS.

Comment: Although gas-fired process heaters that burn liquid during periods of gas curtailment are regulated as gas fired process heaters, they should be allowed to burn other fuels up to ten percent (10%) of the time. VI supports the allowance for liquid firing during periods of curtailment for these heaters, as facilities need the flexibility to continue to operate during periods when gas supply is interrupted. The current proposed rule only allows for 2 days of operation on liquid fuels. VI strongly suggests that this should be changed to 10% of an operating year.

Comment: The proposed regulations should clarify that the Gas 1 subcategory includes propane-fired boilers.

The proposed rules define the Gas 1 category through a series of reference documents. Goodyear finds this confusing, particularly for propane. Goodyear recommends that the rules be revised to specifically include propane as a Gas 1 subcategory fuel.

Response: See response to comment EPA-HQ-OAR-2002-0058-2849.1, excerpt 12 for Gas 1 subcategory and propane fired boilers.

Comment: In the preamble discussion, it appears that the EPA intended to provide that a natural gas-fired boiler that receives less than 10% of the annual heat-input from liquid fuels would be considered a natural gas-fired boiler for purposes of the regulations, and thus only subject to the annual tune-up requirements. However, the language found in the regulation appears to restrict the use of liquid fuels to periods of testing or supply curtailment. Unfortunately, it is possible to envision operating scenarios where "plant-side" equipment may require the use of liquid fuels to provide for maintenance of natural gas systems during periods that do not constitute emergencies as narrowly defined in the proposed rule. Citizens requests that EPA provide for these sorts of operating scenarios in the final rule by clearly providing that greater than 10% of the annual heat input for a combustion unit must come from liquid fuel before the requirements contained in that subcategory apply.

Response: See the final rule for definition of unit designed to burn gas 1. EPA has made limited allowances for burning of other fuels as noted in the definition.

Comment: 63.7575: The definitions for Unit designed to burn gas 1, Unit designed to burn gas 2, and Unit designed to burn oil are a bit confusing. The particular confusion is how the 90% criteria for a gas 1 unit relates to the 48 hour requirement for oil fired units. For example, if a gaseous unit burns oil for more than 48 hours but still meets the 90% requirement, how would this unit be classified?

Response: See response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 223 for the 48 hour a year provision.

A gas 1 unit burning liquid for more than 48 hours, if the oil was burned due to gas curtailment or supply emergencies would be considered to be a gas 1 unit. If the unit burned any oil for any other reason the unit would not be in the gas 1 subcategory.

Comment: PFI suggests the following modification for this definition:

"Units designed to burn natural gas/refinery gas (Gas 1) subcategory includes the collection of all existing industrial, commercial, and institutional boilers and process heaters that collectively burn at least 90 percent (if not specifically designed for dual-fuel use) or at least 70 percent (if specifically designed for dual-fuel fuel use) natural gas and/or refinery gas on a heat input basis on a 12-month rolling average. The heat input from fuel usage during periods of natural gas curtailment or supply interruption as defined under section 63.7575 does not have to be included in this assessment."

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment: Process gases from petrochemical processes must be included in the definition of the Gas 1 Subcategory.

In the proposed rule, the Gas 1 Natural Gas/Refinery Gas (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average. The proposed rule does not define refinery gas and would seem to imply that the definition of refinery gas in 40 CFR §63.641 Subpart CC (National Emission Standards for Hazardous Air Pollutants from Petroleum Refineries) should be used for purposes of the Boiler MACT rule.
Per Subpart CC, refinery fuel gas means a gaseous mixture of methane, light hydrocarbons, hydrogen, and other miscellaneous species (nitrogen, carbon dioxide, hydrogen sulfide, etc.) that is produced in the refining of crude oil and/or petrochemical processes and that is separated for use as a fuel in boilers and process heaters throughout the refinery. This definition includes gaseous mixtures produced in refineries and petrochemical processes but specifies the use of this gaseous fuel for refineries (only).
Since boilers and process heaters are located in refineries and petrochemical processes, the proposed rule should include process gases that meet certain specification, based on heat content. These process gases from petrochemical processes have similar compositions to those stated in the Subpart CC definition (e.g. methane, hydrogen, light hydrocarbons, and other components) that are used as fuel in boilers and process heaters.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: The definition of gas-fired boilers includes those units burning gaseous fuels, which by further definition includes process gases (e.g., coke oven gas). However, the definition of gas-fired boiler is qualified by stating that gaseous fuels cannot be combined with any liquid fuel except during periods of gas curtailment, gas supply emergencies, or periodic testing on liquid fuels. Without clarification of that definition, the exemption for gas fired boilers is potentially negated.
While coke oven gas boilers are primarily designed to burn coke oven gas, usually with natural gas as a back-up fuel, they are sometimes supplemented with blast furnace gas or liquid fuels when the supply of coke oven gas from the coke oven process is interrupted due to operational difficulties or reduced operations necessitated by business conditions or when steam demands elsewhere in the plant that rely on steam from those boilers cannot be met by the available coke oven gas supply to the boilers. It is not clear from the definition of gas-fired boiler whether the terms gas curtailment and gas supply emergencies pertain to commercial natural gas supplies or can be interpreted to include occasions of curtailment and supply deficiencies from the process supplying the gas to the boiler. In the absence of clarifying language in the definition, the occasional use of liquid fuel would place these boilers (as well as any units using any liquid fuel, except in the stated circumstances) into a category that requires stringent emission limits, the

installation of costly emission control equipment, and testing, monitoring and recordkeeping obligations.
If the qualification of liquid fuel usage remains in the definition of gas-fired boiler, we suggest adding further clarifying language that is contained in the definition of a waste heat boiler in the Proposed Rule. As noted above, waste heat boilers are exempt from the rule. The waste heat boiler definition in the Proposed Rule is limited to units designed to use no more than 50% of the total heat input capacity of the unit with supplemental burners. We believe that the environmental and energy conservation benefits of using coke oven gas are comparable to the use of waste heat or blast furnace gas, both exempted under the Proposed Rule, and that the same provisions for using supplemental fuels should apply to units intended to utilize coke oven gas. Accordingly, applying the same rationale, we urge EPA to modify the gas-fired boiler exemption to include those units designed to use supplemental fuels up to 50% of the total heat input capacity of the unit.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Comment Excerpt Number: 12

Comment: The definitions of “units designed to burn liquid fuels” and “units designed to burn natural gas” are inconsistent, contradictory, and should be clarified as set forth below.
EPA should clarify the definitions in the proposed regulation for “units designed to burn liquid fuels” and “units designed to burn gas 2 (other).”
As an example, a boiler primarily operates on natural gas but also has the ability to burn distillate oil. On average, the total heat input of distillate oil to the boiler is 8% (oil is burned for capability testing, and during periods of natural gas curtailment); annual operating hours on fuel oil are 200 hours. If we wish to determine which emission limits the unit is subject to, we would perform the following analysis:

First, we refer to the definition of “units designed to burn gas 1 subcategory”. Based on the fact that the boiler in question burns 92% natural gas on an annual average heat input basis, we would rightly conclude that the boiler is subject to the Gas 1 requirements. However, we then look at the definition of “units designed to burn oil” subcategory. Based on this definition, the boiler in question could be classified a “unit designed to burn oil” since it does burn distillate oil (“any liquid fuel”), and total operation on oil exceeds 48 hours per year. This contradicts the conclusion reached when we applied the definition of “unit designed to burn natural gas” to the same unit.

Celanese is also concerned with the wording in the definition of “unit designed to burn oil” that apparently would allow a boiler that is primarily fueled by natural gas to remain in the Gas 1 category when oil is burned for periods of gas curtailment or supply emergencies, and for testing of liquid fuel systems. This clause is necessary, since the definition of Gas 1 allows limited use of liquid fuels (as long as total heat input remains below 10% on an annual basis). In any case, it is unclear whether “the combined total of 48 hours” condition applies to combined operation during curtailments, emergencies, and testing, or just to testing. Since periods of natural gas curtailment and supply emergencies routinely last for more than 48 hours, we believe EPA’s intent was only to restrict liquid fuels operations for testing purposes, and not during periods of curtailment and supply emergency. This can be clarified in the final rule by adopting revised definitions similar to those proposed below.

Similar confusion can arise for a unit that burns natural gas primarily (92% of annual heat input), and “other gases” (8% of annual heat input). Such a unit meets the definition of “unit designed to burn natural gas”, but also appears to meet the definition of “unit designed to burn gas 2”.
In contrast, consider the simplicity of the definition of “unit designed to burn coal,” which makes it quite clear that a boiler that burns natural gas 92% and coal 8% on an annual heat input basis is a Gas 1 unit and not a coal unit. We suggest that EPA use the same clear wording and logic (using a 10% triggering threshold) when establishing definitions for Gas 2 and liquid units to eliminate possible confusion and to create a consistent approach. We provide the following suggested wording for these definitions:

-Unit designed to burn oil subcategory includes any boiler or process that burns any liquid alone or at least 10 percent liquid on a heat input basis on an annual average in combination with biomass, coal, or gaseous fuel.

-Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that burns any gases other than natural gas or refinery gas alone or at least 10 percent other gas on a heat input basis on an annual average in combination with biomass, liquid, or gaseous fuel.

Response: The definition of gas curtailment as well as the 48-hour provision for periodic testing on liquid fuels has been revised in the final rule.
See response to comment EPA-HQ-OAR-2002-0058-2792.1, excerpt 223 for the 48 hour a year provision.

Comment: ACCCI requests that EPA provide clarification that boilers firing liquefied petroleum gas (LPG) or propane-derived synthetic natural gas (SNG) as a backup fuel are considered a gas-fired boilers. We note that EPA proposes to incorporate ASTM D183503a to define "natural gas" for purposes of this regulation. It is important that any standard incorporated by the regulation be broad enough to encompass the use of propane (a constituent of LPG) as natural gas and not just mixtures. Most LPG mixtures include butane, which reduces the effectiveness of LPG at low temperatures, causing many facilities to substitute propane. Propane (and/or LPG) is mixed with air to create SNG, which should be specifically allowed to be considered as natural gas for purposes of this rule. LPG-based SNG is often used for emergency backup and EPA should make this point explicit in the final rule.

Response: In the final rule, propane was defined to be a type of natural gas.

Comment: Finally, we request clarification that a boiler combusting landfill gas (or similar gaseous fuels derived from landfills or monofills) is considered a gas-fired boiler and not in the biomass category. ACCCI considers these fuels to fall under the definition of biogases, which are included in the definition of gaseous fuels, but we are aware that EPA has taken the position that gas derived from landfills is "biomass" under other rules. We seek clarification that for purposes of this rule it is not the agency’s intent to regulate boiler use of landfill or monofill gas, even if derived in whole or part from materials that might be defined as biomass.

Sulfuric acid is a volatile compound at flue gas temperatures that can partially condense and/or adsorb on the filter and collected solid PM.

Response: See response to comments EPA-HQ-OAR-2002-0058-2761.1, excerpt 15 and EPA-HQ-OAR-2002-0058-2702.1, excerpt 73 for the definition of natural gas needs to be broader to account for non-geological origins of natural gas.
Any gas that does not meet the definition of natural gas or refinery gas must be tested to ensure that it is below the specifications for mercury and hydrogen sulfide.

Comment Excerpt Number: 31

Comment: In setting a maximum 10% annual BTU threshold for the alternate fuel, EPA did not specify how this percentage should be calculated. HOVENSA asserts that the percentage should be based on an annual actual BTUs of the alternate fuel expressed as a percentage of the unit's RATED annual BTU capacity. This is the only way this threshold could be monitored by the facility to avoid unexpected category switching from gas to oil. It would allow the facility to calculate an equivalent barrels of fuel not to be exceeded in any given year, which can be monitored fairly easily. A threshold based on a number expressed as a percentage of the unit's actual total annual BTUs would be a constantly "moving target", making it nearly impossible to monitor and potentially causing units to go in and out of the oil category without warning. As discussed earlier, the BTU content of refinery gases can change significantly due to unpredictable events. Therefore, we propose that the language be clarified to specify a threshold for the alternate fuel expressed as a percentage of the unit's RATED annual BTU. HOVENSA also believes that the baseline for this determination should not be 1 year, it should be 5 or more years. At HOVENSA, units will be taken offline for major repairs and retrofits on a 3 to 5 year schedule which, when a fuel gas producing unit is taken offline, results in short term (20-40 days) increases in oil consumption at units in operation.
[Footnote 30: As noted above, HOVENSA disagrees that this is an appropriate dividing line, because the true dual fuel burners are designed to burn more than 10% of the alternative fuel. HOVENSA also does not support simply dropping co-fired or oil burning equipment into the Gas 1 category if the Gas 1 category is subject to numerical standards. That is because co-fired equipment will have different emissions characteristic both because of design and fuels used. Thus, numerical standards applicable to gas would not be MACT for this equipment.]

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

EPA has adjusted the definition for each subcategory to specify how to calculate the annual heat input threshold to determine the subcategory for the unit. See the final rule for the revised definitions. EPA disagrees that MACT floors should not be established based on tests for units that co-fire fuels. If the test is based on at least 90 percent or more of a given fuel type EPA determined the data is accurate and representative of the other units in the subcategory.

Comment: Work Practices Should Also Be Promulgated For Boilers and Process Heaters Combusting Petrochemical and Chemical Process Gases. All the arguments EPA makes to justify work practice requirements for natural gas/refinery gas apply to virtually all gases. If there are exceptions, (e.g., if further review of the Gas 2 data shows that emissions from coke oven gas are higher than emissions from other gases), then these fuels should be handled as exceptions to a general gas subcategory. Gas-fired units, relative to units firing other fuels, have the lowest emissions and pose the lowest risk of all the subcategories and thus the use of gas should be encouraged, rather than discouraged.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: The characteristics of refinery gas and other gases such as petrochemical gas are extremely similar, which supports the inclusion of petrochemical gas into the Gas 1 category with natural gas and refinery fuel gas. These gases are clean burning fuels and are composed mainly of methane, ethane, and hydrogen.

Recently, an industry review of the composition data of refinery fuel gas and petrochemical gas was performed at member refineries and chemical plants on the gulf coast, utilizing data gathered between January and June 2010. There were approximately 11,200 sample data points used in the comparison. It should be mentioned that the data gathered was based on slightly different sampling methods depending on site/stream as explained below.

In cases where the site collects samples in the field manually, the analysis was performed in a lab. These samples were routinely collected at varying frequencies anywhere from weekly to three times a day. In cases where the site had an online analyzer on the fuel gas stream, the composition was collected and averaged over an hourly period before being recorded.

The comparison of the composition of refinery fuel gas and petrochemical gas indicated a very similar compositional footprint for these two gases (See submittal for Figure 10, comparison of composition). Methane (C1) and hydrogen (H2) are the dominant components for both gases. C2 compounds (ethane, ethylene, and acetylene) constitute the third major component for both gases. All other hydrocarbons, including C3, C4, C5, and C6+ constitute very small fraction of the composition. The remaining components (CO, CO_2, and N2) were very minor as well.

Combustion properties, including higher heating value, Wobbe index, and adiabatic flame temperature, of refinery fuel gas and petrochemical gas were also compared (See submittal for Figure 11 comparison of combustion properties). These properties were all similar for the two gases. The higher heating values were collected along with the composition data for refinery gas and petrochemical gas. The Wobbe indexes and adiabatic temperatures were calculated using the fuel gas composition data collected.

Higher heating value (HHV) is the amount of heat that a given quantity of fuel releases during combustion. The unit of measure for HHV is in the form of energy/quantity. One common unit is British Thermal Units (BTU) per standard cubic foot (Btu/scf). As shown in Figure 10 (see submittal for figure 10), the higher heating values for refinery fuel gas and petrochemical gas range similarly. They are all well above general threshold of HHV for good combustion.

The Wobbe index is a measure of the interchangeability of gases when they are used as a fuel. It compares the energy output of different gases during combustion. The Wobbe index is essential for analyzing the impact of a fuel changeover and is also a common specification of gas appliances. It is defined as higher heating value divided by square root of gas specific gravity. There are three "families" of fuel gases that have been internationally classified based on Wobbe Index. The Family 2 gas has a Wobbe index range of 1045 – 1474 Btu/scf. As shown in Figure 10 (see submittal for figure 10), the Wobbe indexes for both refinery gas and petrochemical gas fall in this range.

Adiabatic flame temperature is the temperature that results from a combustion process that occurs without any heat loss. It is affected by the fuel composition, fuel/air equivalence ratio, and fuel/air preheat temperature. Real flame temperatures are not as high as the adiabatic flame temperature, but the trends are comparable and representative of actual conditions. The peak adiabatic flame temperature for a given fuel and air occurs with a stoichiometric mixture (i.e. right amount of air to just get all fuel oxidized). High flame temperature is desirable for maximizing heat transfer and minimizing incomplete combustion product (e.g. CO). However, high flame temperature increases NOx formation.

The adiabatic flame temperatures at stoichiometric combustion were calculated for the refinery gas and petrochemical gas. As shown in Figure 11 (see submittal for figure 11), the adiabatic flame temperatures were also very similar for the two gases.

In conclusion, both the refinery gas and petrochemical gas are very similar in compositional nature and are extremely clean burning fuels. Both fuels should be categorized with natural gas in the Gas 1 category.

Response: We appreciate the input from the commenter. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 120

Comment: Similarly, natural gas fired units that supplement gaseous fuel with approved RCRA comparable fuels [40 CFR 261.38] should also be treated as Gas 1 boilers and subject only to work practices. Comparable fuels are secondary materials, such as alcohols, that have fuel value and characteristics (e.g., physical properties related to burning and levels of toxic constituents) comparable to or better than fuel oil. The chlorine, mercury, and metals contents of these fuels are limited to below constituent levels of fuel oil, so emissions are in effect already regulated. Therefore, these boilers should qualify for work practices as Gas 1 boilers.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Any other gaseous fuels other than natural gas or refinery gas must demonstrate that they are at or below the specifications in the final rule for mercury and hydrogen sulfide. See preamble for discussion of gas specification. The 48-hour allowance or period of gas curtailment/gas supply emergencies applies to any liquid fuel, so any gas 1 boiler firing compareable liquid fuels for periodic testing or during allowable periods could still qualify as a gas 1 boiler.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 223

Comment: ACC Agrees That Gas Fired Boilers Burning Liquid During Periods Of Gas Curtailment Are Gas Fired Boilers, But Should be Allowed To Burn Other Fuels Up To 10% Of The Time. ACC supports the allowance for liquid firing during periods of curtailment for these boilers, as facilities need the flexibility to continue to operate during periods when natural gas supply is interrupted. However, we believe that the Gas 1 definition should be expanded to allow for additional operational flexibility. EPA has been very consistent throughout the proposal to use 10% as a threshold for movement from one subcategory to another. For example the most stringent – coal – includes units that burn at least 10% coal. The next – biomass – includes units that burn at least 10% biomass and less than 10% coal. The first sentence of the oil (liquid) subcategory includes any liquid fuel, but less than 10 % solid fuel. Therefore, it logically follows that a plain reading of the Gas 1 subcategory would be that EPA intended to include any unit that burns at least 90% gas and less than 10% of any other fuel. However, the second sentence in the oil (liquid) subcategory emphasized above is in contradiction with the Gas 1 definition by implying that any more than 48 hours (2 days) per year of liquid fuel firing would reclassify the unit into the liquid category. We recommend that EPA delete the sentence:

"Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year are not included in this definition.”

Based on the comments above and our previous comment that petrochemical and chemical plant process gases should be regulated under the Gas 1 subcategory, ACC proposes the following definition for Gas 1 boilers:

"Unit designed to burn Gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas, propane, refinery gas, or off-gas streams for petrochemical and chemical plant processes on a heat input basis on an annual average and less than 10 percent of any solid or liquid fuel."

Response: In the final rule the 48-hour per year provision does not include periods of gas curtailment and supply emergencies. The 48-hour provision is specific to periods of testing. EPA has determined that only in these limited circumstances is a unit allowed to burn fuels other than gas 1 fuels and the gas 1 fuel category does not include all units that burn 90 percent gas 1 and 10 percent of any other fuel type.

Comment Excerpt Number: 8

Comment: Should boilers and process heaters that are specifically designed for dual-fuel use be allowed more flexibility than the 90% threshold proposed in the definition — As discussed in Section IV.A in the preamble to this proposed rule (75 FR 32017), the definition of this subcategory is based on information collection activities which concluded that "boilers are designed based on a primary fuel type (and perhaps to burn a backup fuel) and can encounter operational problems if another fuel type that was not considered in its design is fired at more than 10 percent of the heat input to the boiler." PFI would tend to agree with this conclusion, however has concerns related to applying the same threshold to boilers and process heaters that are dual-fuel designed. The major concern is the potential but likely loss of any negotiating power related to the renewal of natural gas contracts with suppliers, which in turn could result in increased natural gas costs and the incentive for facilities to permanently switch from gas, which is considered a "clean" fuel, to their cheaper but "dirtier" alternative fuel (i.e., fuel oil). Therefore, PFI recommends that more flexibility be provided for the use of alternative fuels in boilers and process heaters that are specifically dual-fuel designed, such as a 70% threshold — a balance that would both allow facilities to maintain some of its negotiating power while at the same time discouraging abuse of the intent of this regulation.

Response: See response to comments EPA-HQ-OAR-2002-0058-2840.1, excerpt 12 and EPA-HQ-OAR-2002-0058-2875.1, excerpt 9 for use of back up fuels within Gas 1 units and appropriateness of 10% fuel use limit.

Subcategories: NG/RFG Metallurgical Furnaces

Commenter Name: Michael Palazzolo
Commenter Affiliation: Alcoa Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2967.1
Comment Excerpt Number: 1

Comment: Alcoa fully supports EPA's decision to establish a separate subcategory for "metal processing furnaces". Such furnaces are used in the aluminum industry to preheat metal for further processing and to heat treat metal to effect specific physical properties. A separate subcategory is appropriate for these furnaces because they differ significantly from other types of process heaters. Metal processing furnaces consist of large multi-zoned ovens with many small gas-fired burners. These furnaces are batch operated and typically have between 12 and 140 burners, with each burner having a capacity of 0.1 to 2 mmBTU/hr. The burners are fired into separate combustion chambers and are modulated between high-fire, low-fire and pulse (cycle on-off) to reach and control target temperatures in each furnace zone. The burners therefore operate over a wide turn-down range (burner output ranges from 100% to <10% of capacity) and remain in a "startup/shutdown" rather than steady-state mode most of the time.

Response: EPA agrees with the commenter that a separate subcategory is appropriate for these furnaces and has retained them in the final rule.

Comment: For the metal process furnace subcategory, the agency makes much of asserted differences in design and operation of these units compared with other industrial boilers and process heaters, id., arguing that these differences create distinct emissions characteristics justifying a separate subcategory (although in fact, EPA proposes work practice standards for this subcategory as well). What EPA really is doing here however, is creating subcategories in order to set up work practice standards that avoid the application of MACT-based emissions limits to a substantial part of the regulated industry. This is clearly unlawful.

Response: For the technical design reasons stated in response to comment EPA-HQ-OAR-2002-0058-2967.1, excerpt 1, and the policy reasons stated in the preamble EPA has maintained the metal process heater subcategory in the final rule and has also maintained the work practices for gas 1 type boilers and process heaters.

Comment Excerpt Number: 1

Comment: EPA proposes to include the 'Metal Process Furnaces' subcategory to distinguish natural gas-fired process heaters in the metals production industry from natural gas-fired process heaters used in other industries. The Association supports a separate subcategory for Metal Process Furnaces because these units have different design and operating characteristics, including variable heating regimes, intermittent burner operation and batch processing.

The Aluminum Association surveyed its members in the spring of 2009 to assess the types and number of Metal Process Furnaces that meet the definition of "Process Heater" under the Boiler MACT proposal. The data from the survey is summarized in the table that follows. Although not all furnaces were likely surveyed since only Aluminum Association members were included, the total of 253 furnaces represents a substantial portion of the aluminum Metal Process Furnaces operated in the U.S.

[See submittal for Table summarizing survey results]

Response: See reponse to comment EPA-HQ-OAR-2002-0058-2967.1, excerpt 1.

EPA acknowledges the comment and has retained the subcategory for metallurgical furnaces.

Comment: "Other Gas" Boilers

When EPA's calculation of the MACT floor for the "other gas" category is set against its calculation of the MACT floor that would apply to natural gas/ refinery gas boilers and to metal process furnaces if a work process standard were not proposed, it is clear that the MACT limits for the "other gas" boilers are comparable and in most cases lower than those that would apply to the exempted boilers. This suggests that on average "other gas" boilers perform as well as those exempted.

EPA cites the very high expense of bringing all the nearly 12,000 exempt boilers into compliance with its calculated MACT standards. But when these costs are broken down on a per-unit basis they are found to be comparable to the costs for the "other gas" units that are subject to MACT and in the same range (order of magnitude) as all the other units subject to the proposed rule.

Among the boilers now proposed for the work process standard are natural gas fired metal process furnaces. There is no evidence to suggest that metal process furnaces that burn fuels such as coke oven gas or blast furnace gas perform any worse than such furnaces that burn natural gas.

As such, they should be included in the current metal process furnace category or be treated the same as USW proposes “other gas” units be treated.

Response: EPA has modified the definition of the gas 1 subcategory in the final rule. See the preamble for discussion of the gas specification. Any boiler firing gaseous fuels that meet the specification will continue to qualify for work practice standards.

Comment: The Metal Process Furnace Subcategory Should Include Furnaces That Combust Process Gases

The steel industry employs numerous metal process furnaces, including reheat furnaces, annealing furnaces, and heat treating operations. Some of these are direct-fired and are not covered by the rule, but others are indirect fired units that would classify them as process heaters. AISI supports the separate classification of “metal process furnaces,” which EPA found to be a “class of natural gas-fired process heaters that are designed and operated differently compared to typical process heaters.

The proposal correctly identifies the technological and operational issues that justify creation of a metal process heaters subcategory. However, the Proposed Rule further circumscribes that group by defining it to include only units that combust natural gas. Id. (“ [t]he process heaters used in metal processing are natural gas-fired and include annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, and heat treat furnaces”). While many metal process furnaces do use natural gas, others recycle (or can be used to efficiently recycle) process gas, such as coke oven gas, in order to reduce the amount of additional natural gas needed to operate these units.

The type of gas combusted in a given metal process heater has nothing to do with the technical and operational distinctions that render them unique, including the fact that they are designed with multiple burners in a single unit and rarely operate in a steady-state condition. Rather, those same findings apply equally to all metal process heaters combusting any gaseous fuel. As such, there is no legitimate basis for limiting this subcategory to natural gas-fired units and EPA should redefine this subcategory to include furnaces combusting any gaseous fuel.

Response: EPA acknowledges the comment and has retained the subcategory for metallurgical furnaces. EPA disagrees with the commenter and that only metal process heaters firing natural gas meet the definition of this subcategory. Metal furnaces firing solely natural gas qualify for the metal process heater subcategory.

Comment: EPA Should Expand the Category of "Metal Process Furnace"

AISI requests that EPA revise the definition of metal process furnace to include the phrase "includes, but is not limited to" to acknowledge the fact that there may be other furnaces that should be excluded. Examples of such furnaces, in addition to annealing, preheat, reheat, aging and heat treat furnaces, include:

Stress relief furnaces, which are similar to aging and heat treat furnaces in that they are used to heat and cool metal to eliminate stresses from forging and similar activities.

Galvanizing/ galvanneal furnaces, which are similar to annealing furnaces in purpose and operation, but operate on a continuous (strip) rather than batch (coil) basis. Like annealing furnaces, these units fire sporadically as necessary to achieve an annealed consistency in the metal.

Alternatively, we request that EPA specifically add both of these units to the list of "metal process furnace" examples included in proposed section 63.7575.

Response: EPA has modfied the final rule to include homogenizing furnaces but has not modified the definition to include all other furnace types. Other determinations may be made on a case-by-case basis.

Comment: A vast majority of our industry's boilers and process heaters rely on clean-burning fuel, whether it's natural gas, refinery gas, or gas from our petrochemical operations for the efficient operation of our facilities. However, we are not alone as many other industries, institutions, and government facilities also rely on these gaseous fuels to keep this nation going efficiently. EPA should continue to recognize the benefit of these clean fuels.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel

specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury.

Comment: We also note that there is very little difference between the emissions from the top performing sources in the Gas 2 subcategory as compared with the Gas 1 subcategory. As a result, EPA would be justified in concluding that the Gas 1 and Gas 2 subcategories should be combined into a single gas-fired subcategory, which would be regulated by work practice standards for the reasons EPA explains in the preamble. At a minimum, units fired with process gases generated in chemical plants, pulp and paper plants, and similar operations should be included in the Gas 1 subcategory because the emissions data show very little difference in performance between units at these facilities and Gas 1 units.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: Some of our members are investigating projects where biomass will by pyrolized to create syngas, which will be burned in mill boilers in place of natural gas. Regulating this syngas as Gas 2 and subjecting it to stringent emission limits does nothing to incentivize innovative projects like these that will reduce a mill's reliance on fossil fuels.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Comment: EPA proposes three subcategories for gas-fired units: non-metal boilers and process heaters firing natural gas and/or refinery gas (Gas 1); metal boilers and process heaters firing natural gas and/or refinery gas (metal process furnaces); and boilers and process heaters firing other gaseous fuels (Gas 2). We only deal with the Gas 1 and Gas 2 subcategories in these comments. EPA proposes a work practice standard for the Gas 1 subcategory and numerical emission limits for the Gas 2 subcategory. We have reviewed the information regarding HAP emissions from Gas 1 and Gas 2 fuels and made an assessment as to whether aggregation of all gas fuels under a work practice standard is technically sound and supported by the available data and our knowledge of the fuels that comprise those categories. Our review is included as Attachment B.

That review is divided into the following parts:

* HAP formation and emissions in gaseous fuel combustion
* Review of the available emissions data; and
* Discussion and Findings

From this technical review we reached the following conclusions.

* Pilot scale and field data studies support the conclusion that emissions of organic HAPs from gaseous fuels are not significantly affected by fuel type. The data gathered by EPA show that emissions of HCl, dioxins/furans, CO and PM from Gas 2 fuels are similar to or lower than those for Gas 1 fuels (neglecting CO data for four Gas 2 Process Gas fired units that strongly bias that data set).

* With the exception of mercury emissions from certain fuels, the data does not support treating Gas 1 and Gas 2 fuels differently to assure low emissions of HAPs. With the exception of mercury and HCl, combustion tuning to maintain operating conditions within the range for good combustion is expected to maintain low HAP emissions.

Recommendation: With very limited exceptions, the technical data developed by EPA indicate no HAP emission basis for treating Gas 1 and 2 differently. Thus, the proposed Gas 1 and Gas 2 subcategories should be combined.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: Review of ICR Emissions Data

EPA has collected emissions data from boilers and process heaters firing a variety of gas fuels. These include fuels such as landfill gas and coke oven gas, and others that are less distinct that have been labeled as “Process Gas” and “Petrochemical Gas.” The HCl data population for Gas 1 and Gas 2 fuels not fired in metal furnaces consists of HCl emission test results for natural gas, refinery gas, coke oven gas (COG), biogas/natural gas, and landfill gas (Figure 2, top). Two of the three units listed as firing COG actually burn petroleum coke, not COG.

The 95% confidence intervals of the HCl data for each fuel can be used as a convenient visual indication of whether any observed differences in mean emissions among the different fuels are significant at the 95% confidence level. If the confidence intervals overlap, the differences can be not significant. This is rather simplified statistical analysis, but many of the data sets for individual fuels are too small for more sophisticated statistical methods such as t-tests to be meaningful. By inspection, it can be seen that the mean and confidence intervals for all of the Gas 2 fuels except biogas/natural gas lie within the confidence intervals for the Gas 1 subcategory, and within those for natural gas and refinery gas separately (Figure 2, bottom). The mean is slightly lower than that for natural gas. This indicates that the average HCl emissions from Gas 2 fuels are not significantly different from those for either natural gas or refinery gas.

The mean HCl emission for biogas/natural gas is much lower than those for the Gas 1 fuels, and the confidence interval is relatively narrow. No HCl emission data was found in the test report file provided by EPA for this unit, so they could not be verified. In previous versions of EPA‘s database, there were instances of phantom data caused by errors in extracting data from the electronic reporting tools (ERT and spreadsheets) which may be the case here. Assuming the data are correct, however, one would conclude there is no reason to create a separate subcategory for biogas/natural gas based on its HCl emissions compared to those from natural gas and refinery gas.

In the mercury data set, results are reported for natural gas, refinery gas, hydrogen, coke oven gas (COG), landfill gas, biogas/natural gas, and blast furnace gas (Figure 3). Two units firing petroleum coke are included in the COG group. Units firing at least 90% blast furnace gas are explicitly excluded from regulation under the proposed rule in 63.7491(j), but the results for one unit remain in EPA‘s database. Mercury emissions for landfill gas and biogas/natural gas units are at least as low as Gas 1 fuel units.

The dioxins and furans TEQ data set includes results for natural gas, refinery gas, landfill gas, biogas/natural gas, COG, blast furnace gas and heavy recycle/NG. Also, communications with the facility indicate that the heavy recycle/NG unit fires liquid fuel, and hence these data also should be excluded from the analysis. Comparing the remaining fuels, the confidence intervals for landfill gas, biogas/natural gas, and coke oven gas all overlap that for Gas 1 fuels. Thus, the differences in mean dioxins and furans TEQ emissions are not significantly different among these fuels.

The CO data set includes a wider variety of fuels and blends, including natural gas, refinery gas, COG, blast furnace gas, landfill gas, biogas/natural gas, biogas, natural gas/process gas, process gas, petrochemical process gas, natural gas/petrochemical process gas, and vent gas for APC (Figure 5). These fuels are not defined in terms of composition, heating value, or other characteristics so it cannot be said to what degree they are truly different from each other. Among these, the COG data set includes a number for petroleum coke fired units. With the exception of Process Gas, all of the Gas 2 fuels lie within or below the range of CO produced by Gas 1 fuels. The mean and variability of CO within the Process Gas group is substantially greater than the other fuels, with the upper range extending into the thousands of ppm. The mean and confidence intervals are strongly biased by three units at one facility and one unit at a second facility that have an average CO concentration of 2570 ppm (12 data points). Because there are many other units firing Process Gas with lower emissions, it seems likely that CO emissions are high due to characteristics of the units in which they are fired. The remaining 232 of 244 CO data points within this fuel group fall below approximately 200 ppm, with a mean of 13 ppm. This compares favorably with, even lower than, CO levels from Gas 1 fuels.

Mean filterable PM emissions for all Gas 2 fuels fall within the 95% confidence bounds for either natural gas or refinery gas, with the exception of data for one unit reportedly burning COG with natural gas that is much higher than the other fuels (Figure 6). This consists of a single data point from a 1995 test, providing no information on variability, so its representativeness must be questioned.

It should be noted that data sets for several of the fuel groups are quite small, with fewer than 10 data points. For such small data sets, confidence intervals are not reliable indicators of the full population, so it is difficult to say with certainty that these fuels do or don't produce emissions similar to the other fuels. In most cases, this is an argument for aggregating these fuel groups with other groups that have larger populations to produce a statistically valid analysis.

Discussion and Findings

The ICR data show that average emissions of HCl, dioxins/furans TEQ, CO and PM emissions among various Gas 2 fuels that do not combust process vent gas containing chlorine are at least as low those for Gas 1 fuels (neglecting CO data for four Gas 2 Process Gas fired units that strongly bias the mean CO level of that relatively large data set).

The data indicate that in most cases the mean emission levels for Gas 2 fuels are within the range and confidence intervals for individual Gas 1 fuels, suggesting that differences in gas fuel characteristics to not have a first order impact on HAP emissions. The presence of a small number of very high outliers among a large set of CO data for Process Gas suggests that system characteristics may have greater significance than fuel characteristics for this group. This clearly indicates poor combustion conditions, and an opportunity for CO emission reduction via combustion improvement.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: The vast majority of Gas 2 units in the ICR CO data set have no emission controls (Figure 1). All but two units in the floor have no controls. Data for units with no controls also span the full range of reported CO emissions. Four units are equipped with flue gas recirculation (FGR) for NOX emissions control. FGR reduces NOX by recirculating cooled flue gas from the boiler/heater outlet into the combustion zone via mixing with the combustion air or through injection ports, thereby reducing peak flame temperatures and oxygen availability. There is one unit reported with a cyclone, which is a boiler that burns biogas produced from gasification of rice hulls and the fuel contains ash resulting from inorganic matter in the gasifier feed. One unit is reported to have a fabric filter with limestone injection; this unit is categorized as firing coke oven gas, but review of the ICR documentation shows this is actually fired with petroleum coke, a solid fuel. Although four units with FGR span the lower decade of CO emissions, there is no reason to expect FGR should result in lower CO emissions; in fact, increased CO is often reported when FGR is added since it decreases combustion temperatures, oxygen availability and furnace residence time which inhibit complete CO oxidation.

Response: See response to comment EPA-HQ-OAR-2002-0048-2632.1, excerpt 19 for inadequacies of the Gas 2 dataset.

EPA did not base its floor calculations on the controls installed in each subcategory but instead based on the emission performance of each of the units in the subcategory. EPA has also adjusted several units firing petroleum coke from the gas 2 to solid fuel subcategory based on comments received during the public comment period.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 265

Comment: The Gas 2 data set for HCl includes data for units with no controls and limestone injection/fabric filter (Figure 6). A single unit with no controls comprises the MACT floor. Investigation of the test reports and correspondence from the facility submitted to EPA confirm that the two units with limestone injection/fabric filter (EPA #4 and #8) are actually fired on petroleum coke, not coke oven gas. The single unit comprising the MACT floor (EPA #1) was found to fire a liquid fuel. Therefore, these units should be removed from the MACT floor analysis for Gas 2. This leaves HCl data for only five Gas 2 units, all of which have no controls. Thus, no conclusions with respect to HCl control technology can be drawn from these data.

Response: See response to comment EPA-HQ-OAR-2002-0048-2632.1, excerpt 19 for inadequacies of the Gas 2 dataset.

Comment: Hydrogen fueled off-gases

DuPont believes that process off-gases derived from natural gas or petrochemical feedstocks that have even lower heating values due to their hydrogen content than typical hydrocarbon gases also provide useful combustion energy and should be treated similarly to Gas 1 units. These process gases provide stable combustion characteristics and typically have low contaminant content due to the nature of the processes. The EPA hydrogen fueled flare document- Basis and Purpose Document on Specifications For Hydrogen-Fueled Flares, Emission Standards Division, U.S. Environmental Protection Agency Office of Air Radiation, Office of Air Quality Planning Standards, March 1998, documents the basis for establishing minimum hydrogen content for unsupported flare combustion. The testing documented established the minimum hydrogen content of 8% by volume as that proven adequate for sustained combustion without support fuel (nonassisted flare operation).

As noted in the referenced document (also submitted for reference), hydrogen has a lower heat content than organics commonly combusted in flares meeting the prior existing flare specifications and cannot, therefore, be used to satisfy prior control requirements. However, since the combustion of hydrogen is different than the combustion of organics, and the test report demonstrates a destruction efficiency greater than 98 percent, the EPA believes that hydrogen-fueled flares meeting the recommended specifications will achieve a control efficiency of 98 percent or greater. This level of control is equivalent to the level of control achieved by flares meeting the prior existing specifications. In addition to achieving the same destruction efficiency of VOC or organic HAP, these recommended specifications have the added advantage of reducing the formation of secondary pollutants; since the combustion of supplemental fuel would not be required by hydrogen-fueled flares to meet the existing flare specifications. Therefore, DuPont recommends a similar approach be used to establish 8% by volume as a minimum hydrogen content in hydrogen fueled process gases as a criterion that allows its use as a fuel in boilers and process heaters under the Boiler MACT rule and allow consideration as Gas 1 with a work practice MACT approach.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Jeffrey R.Klieve
Commenter Affiliation: Monsanto Company
Document Control Number: EPA-HQ-OAR-2002-0058-2754.1
Comment Excerpt Number: 8

Comment: Monsanto requests that USEPA consider including other gaseous fuels that do not contain HAPs in the Gas 1 category. Monsanto operates a natural gas-fired boiler capable of burning up to 70% hydrogen gas, which is recovered from an on-site chemical process. The hydrogen stream contains no HAPs. Burning this hydrogen stream displaces the burning of natural gas, which does contain HAPs such as BTEX at low level concentrations.

Including gaseous fuels such as hydrogen in the Gas 2 category subjects these boilers to requirements which achieve no further reduction of HAPs to the environment, yet require the source to comply with extensive initial and perennial performance testing, recordkeeping, fuel analyses, and CO CEMS for units 100 MMBtu/hr or greater.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: A hydrogen plant's tail gas should be regulated similar to natural gas. Tail gas should not be regulated as "other gas".

EPA established emission limitations and work practice standards for 11 subcategories in the proposed Boiler MACT regulations. Units designed to burn "other gas" is one of the 11 categories (63.7499(a)(10)) but there is no definition in 40 CFR 63.7575 even though 63.7499(b) states "Each subcategory is defined in §63.7575". This will drag all the units that burn gaseous material that does not meet natural gas or refinery gas into the "other gas" sub category (63.7499(a)(10)) and be required to comply with stringent Table 4 emission standards for particulate matter and carbon monoxide limits that apply.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Mark Calmes
Commenter Affiliation: Archer Daniels Midland Company

Comment Excerpt Number: 2

Comment: EPA did not take into account in the establishment of the Gas 2 MACT Floors the extreme diversity of Gas2 fuels and the units in which they are combusted. The proposed limit for CO of one ppm is unattainable for most units burning process gas. If it were attainable, it would not represent the point of optimum combustion efficiency for most boilers and process heaters, thereby raising emissions of other pollutants.

Response: See response to comment EPA-HQ-OAR-2002-0048-2632.1, excerpt 19 for inadequacies of the Gas 2 dataset.

See the preamble for how the CO floors were adjusted to incorporate instrument measurement error and a revised expected dataset of units in the gas 2 subcategory.

Commenter Name: Dave Copeland
Commenter Affiliation: Praxair Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3141
Comment Excerpt Number: 2

Comment: EPA established PM and CO limits for boilers/process heaters as a surrogate to metal HAPs and Organic HAPs. Units burning gaseous fuels similar in nature for organic components and metal components as natural gas should be in the same category as natural gas. Unfortunately, in the proposed rule, units burning gaseous fuels similar in nature for organic components and metal components as natural gas still have to comply with the stringent limits of the "other gas" category.

For example, tail gas produced in hydrogen production process is similar to natural gas and unfairly needs to comply with the stringent limits of the "other gas" category. Praxair is a major producer of hydrogen utilized in the refinery, chemical and electronics industries. Modern, large-scale hydrogen plants that use natural gas as a feedstock are the primary means of meeting the growing industry demand for hydrogen.

A modern steam methane reformer (SMR) based hydrogen plant consists of four primary subsystems (see Figure 1). Natural gas is used both as a feedstock and as a fuel. The natural gas stream is split, and the majority is used as process feed, which is compressed and desulfurized before entering the reformer reactor tubes. Gas _leaving the reformer enters a high-temperature shift reactor, where carbon monoxide (CO) is reacted with steam.to produce additional hydrogen. After cooling, hydrogen-rich gas from the shift reactor is processed by a Pressure Swing Absorption (PSA) unit for purification to product hydrogen specifications. The PSA tail gas (Tail

Gas), consisting of unreacted methane, CO, nitrogen, and unrecovered hydrogen, is recycled for mixing with natural gas and used as fuel in the reformer furnace. This clean-burning "tail gas" provides most of the reformer fuel (-75-90%), the emissions are,much lower than if the same amount of heating were provided by natural gas (because of the desulfurization step), which itself is considered to be "clean-burning". It should be noted that this "clean burning" characteristic of hydrogen plants has been recognized by EPA before in New Source Performance Standards for Petroleum Refineries (40 CFR Part 60 Subparts J and Ja) as inherently low in sulfur and therefore exempt from sulfur monitoring. [See submittal for Figure 1. Steam Methane Reformer Process Flow Diagram.]

The SMR is a process heater as defined by the proposed rule. Depending on where the hydrogen plant is located, the tail gas would fall under either a natural gas/refinery gas category or as an "other gas" category. If the hydrogen plant is located and regulated as part of a refinery, the tail gas would be viewed as a refinery gas and the combined stream of natural gas and tail gas would be regulated the same. If the hydrogen plant is not part of a refinery, the tail gas would be considered an "other gas" as per the proposed rule. This puts the natural gas and the tail gas in two different regulatory categories which increases the complexity of compliance.

Since tail gas is derived from natural gas, is made up of methane, CO, CO_2, nitrogen and hydrogen and is a clean burning fuel, comparable to natural gas, it would seem more appropriate for tail gas to be regulated similar to natural gas rather than as "other gas".

Recommendation: Include Hydrogen Plant Tail Gas or similar process gases derived from natural gas processing in the same subcategory as 63.7499(a)(9). This can be done by revising 63.7499(a) (9) as "Units designed to burn natural gas/ refinery gas/ other gas derived from natural gas/refinery gas processing. Also including a definition for other gas derived from natural gas/refinery gas processing.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: The limits for other MACT pollutants are not well established due to the inadequacies of the database, and the proposed requirement to test for them periodically would be a disincentive for the use of process gas. For example, EPA does not have enough data on combustion of anaerobic digester gas to differentiate it from natural gas. As such, classification of anaerobic digester gas as Gas 2 is unreasonable.

Response: See response to comment EPA-HQ-OAR-2002-0048-2632.1, excerpt 19 for inadequacies of the Gas 2 dataset.

EPA revised is definition of gas 1 and based its gas 2 floor on all gas data that were not demonstrated to meet the specifications. Based on the data available in the record biogas meets the specifications of the final rule. Each gaseous fuel must test its fuel type to demonstrate that it meets the specification.

Commenter Name: Chelly Reesman
Commenter Affiliation: JR Simplot Company
Document Control Number: EPA-HQ-OAR-2002-0058-3162
Comment Excerpt Number: 4

Comment: Fuels Subject to the Proposed Rule
Simplot generates biogas from wastewater treatment facilities associated with potato processing. This gas is used to supplement natural gas or hydrogen fuel in our boilers. Biogas is one of the listed types of gaseous fuels. Since it is not a refinery gas or a natural gas, boilers firing biogas fall under the category "Unit designed to burn gas 2 (other)". Please confirm our understanding that biogas fueled units are subject to the emission limits specified for "Units designed to burn other gases".

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Commenter Name: Holly R. Hart

Document Control Number: EPA-HQ-OAR-2002-0058-2964.1
Comment Excerpt Number: 11

Comment: A large fraction of “other gas” units are biogas units. These include boilers where waste gasses such as those from treatment ponds are used as fuel instead of allowed to be vented directly to the environment. All of EPA’s reasoning that it applied to the natural gas/refinery gas units and the metal process furnaces applies equally well to the “other gas” boilers.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 19

Comment: We believe the EPA's estimate of 199 sources in the Gas2 category is extremely low. Dow has approximately 30 sources that may be in this category and we suspect that the true number of total sources in this category is closer to 1,000 - 2,000. Thus, we urge EPA to reconsider the entire proposal for the "Other Gases" category and to establish work practice standards in lieu of concentration based emission standards at this time.

In addition, it should also be noted that the boiler exhaust temperatures are much lower than design during low load conditions, such as stand-by operations. Thus, the use of an oxidation catalyst to reduce CO emissions to < 1 ppmv will not be effective during times of low load operation.

Response: EPA has based its Gas 2 inventory and its revised Gas 2 floors on data made available to the Agency in two separate ICRs as well as voluntariy data submitted during the public comment period. Based on the revised definitions of gas 1 to include the gas specification EPA also expects more units to qualify as gas 1 instead of gas 2.

Comment: PA Should Adopt the Work Practices for Gas 2 Fuel Boilers as the MACT Floor. All the arguments EPA makes to justify work practice requirements for natural gas/refinery gas apply to virtually all gases. If there are exceptions, (e.g., if further review of the Gas 2 data shows that emissions from coke oven gas are higher than emissions from other gases), then these fuels should be handled as exceptions to a general gas subcategory. Gas-fired units, relative to units firing other fuels, have the lowest emissions and pose the lowest risk of all the subcategories and thus the use of gas should be encouraged, rather than discouraged.

Integrated chemical plant sites strive to be as energy efficient as possible. One way to promote energy efficiency is to capture off-gas from petrochemical and chemical plant off-gas streams and re-use these streams as fuel in a variety of combustion sources. Plant sites are designed to use many types of “Gas 2” streams as a fuel in order to have energy efficient operations. If Gas 2 fuels are subjected to stringent emission limits instead of work practice requirements, the rule likely will force facilities to dispose of process off-gases in other types of combustion sources including flares, which results in more natural gas being used, inefficient operations, and an increase in greenhouse gas emissions.
The characteristics of refinery gas and other gases such as petrochemical gas are extremely similar, which supports the inclusion of petrochemical gas into the Gas 1 category with natural gas and refinery fuel gas. These gases are clean burning fuels and are composed mainly of methane, ethane, and hydrogen.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: The Gas 1 subcategory should include boilers and process heaters fired with hydrogen gas. Hydrogen is generated as a byproduct of our Chlor-Alkali manufacturing process. After purification of the hydrogen, OCC sells it as a commercial product to industrial and medical gas manufacturing facilities or uses it onsite as a fuel. Two of our locations fire hydrogen in combination with natural gas in their boilers. Other OCC locations burn hydrogen in their waste heat boilers. Attachment A includes data comparing the composition of hydrogen to natural gas, derived from fuel gas samples collected during a November 2002 stack test at our Taft, Louisiana Chlor-Alkali plant. The second set of data includes a comparison of hydrogen to natural gas from a September 2007 stack test from our LaPorte, Texas Chlor-Alkali facility. The third set of attached data includes more recent natural gas analyses at this same plant. In addition, our Wichita, Kansas facility tested its hydrogen in June of 2010. Sample results indicated less that 10 ppb (the R&D lab limit of detection) of methylene, chloride, chloroform, carbon tetrachloride, 1- bromo2-chloroethane, toluene and perchloroethylene. Our hydrogen-producing ChlorAlkali facilities also routinely analyze their raw material brine for mercury and the results are routinely less than the applicable limits of detection. Finally, hydrogen analyses taken in 1997 at our Ingleside, Texas Chlor-Alkali facility indicated chloride values less than 8 ppb. Therefore, historic data indicates that firing this byproduct hydrogen has minimal potential to generate HCL, Dioxin/ Furans, or mercury emissions. Therefore, hydrogen is a cleaner burning fuel than natural gas and hydrogen should not be included in the "Other Gas, Gas 2 category." We respectfully request that EPA amend the final rule to include hydrogen gas-fired boilers and process heaters in the Gas 1 subcategory.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment Excerpt Number: 3

Comment: EPA Should Classify the Combustion of Hydrogen Gas as a Gas 1 Fuel from Chlor-Alkali By-Product Production. The byproduct production of hydrogen gas from chlor-alkali production facilities is estimated at 389 thousand metric tons of hydrogen annually which is equivalent to the annual fuel consumption of 1.9 million light-duty hydrogen vehicles. The process itself involves the electrolysis of salt water which, in combination with other process steps,splits salt (NaCl) in solution into sodium hydroxide (NaOH), chlorine gas and hydrogen gas. In this process, hydrogen is a byproduct produced in a comparatively pure form.

This hydrogen byproduct can be sold directly into commerce where it has a myriad of uses or used to produce hydrochloric acid (HCl). One of the major uses however takes of Hydrogen's heating value using it as a high quality fuel to produce electricity or steam. The chlorine chemistry industry has long employed cogeneration, an energy efficiency attained through the coproduction of electricity and process heat (also called combined heat and power or CHP) from a plant that is located at the chemical manufacturing facility. Significant efficiencies are gained from the productive use of the by-product heat, usually in the form of steam. While the efficiency gains can vary widely among individual sites, at its peak co-generation can be over 70 percent efficient.

The combustion of Hydrogen does not emit carbon dioxide or other greenhouse gases thus should be considered a "clean fuel". Recovering and burning the hydrogen also preserves existing reserves such as coal, oil and natural gas. Considering the vital and growing role of energy in global economic and environmental issues, the chlorine industry is likely to increase its use of co-generation. Because hydrogen is comparatively pure and considered a clean fuel, EPA should classify the cogeneration use of hydrogen fuel as a Gas 1 fuel.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment Excerpt Number: 3

Comment: The LCSFA urges EPA to adopt a definition of natural gas under Section 63.675 that explicitly treats syngas equally as compared to natural gas and refinery gas. We suggest that EPA adopt a definition similar to that used in the Subpart YYYY standards for stationary combustion turbines. If EPA is concerned about the purity of syngas, it could require that syngas meet minimum specifications as it did in the Part 261 hazardous waste regulations. As syngas for the FT process must be extremely clean to avoid poisoning the FT catalyst, syngas used in boilers at integrated biorefineries would meet these specifications.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Comment: A work practice standard should be applied to integrated has combined cycle units

Boilers and process heaters that burn refinery gas and natural gas emit very low levels of HAPs. As a result, emissions from these units pose little risk to public health and safety. EPA has, therefore, proposed to set a work practice standard for existing gas-fired ("Gas 1") industrial boilers and process heaters, rather than specific emissions limitations. Integrated Gas Combined Cycle (IGCC) units employ the use of a gasifier to convert coal into gas and then remove impurities from the resulting gas before combusting it in a gas turbine. This process of removing impurities from coal-derived gas results in emission levels of particulate matter, sulfur dioxide, and mercury from IGCC units that compare to those of other gas-fired units. Therefore, such coal-derived gas should he added to the Gas 1 category of fuels, and IGCC units should be subject to work practice standards rather than strict MACT floors. Applying such a standard would also incentivize the development of IGCC technology, which, with additional research, development and deployment, could become a promising option for reducing CO_2 emissions in coal-fired industrial boilers and process heaters.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 118

Comment: An ACC member company has a "Gas 2" stream that consists of the fuel produced by on-site ethylene production plants. The ethylene process off-gas is similar in composition to natural gas.

Comparison of Cobustion Propeties

This off-gas stream is a very clean fuel and the composition is as shown by the table below. The main difference is that this stream contains a significant amount of hydrogen which is a very clean fuel to use.

Column A represents a natural gas stream and Column B represents ethylene process off-gas from one of the member’s sites. This table further demonstrates that Gas 2 boilers should be subject to work practice standards like Gas 1 boilers because the fuel characteristics are similar or better.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel

specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 119

Comment: ACC also believes that EPA should clarify that boilers and process heaters burning hydrogen gas alone or with natural gas are Gas 1 boilers and subject only to work practice requirements. Hydrogen gas does not contain any HAP and burns cleaner than natural gas, so these units should be regulated as Gas 1 units and not be required to install costly controls and monitoring equipment.

Hydrogen is a common by-product gas of many chemical manufacturing processes and is routinely burned in boilers on-site in place of natural gas. For example, hydrogen is a by-product of the chlorine production process. The byproduct production of hydrogen gas from chlor-alkali production facilities is estimated at 389 thousand metric tons of hydrogen annually which is equivalent to the annual fuel consumption of 1.9 million light-duty hydrogen vehicles. The process itself involves the electrolysis of salt water which, in combination with other process steps, splits salt (NaCl) in solution into sodium hydroxide (NaOH), chlorine gas and hydrogen gas. In this process, hydrogen is a byproduct. In some facilities, approximately 10 percent of the hydrogen produced is used on site to produce hydrochloric acid (HCl), while larger portions are combusted on site to meet steam and power production needs. The chlorine chemistry industry has long employed cogeneration, an energy efficiency attained through the coproduction of electricity and process heat (also called combined heat and power or CHP) from a plant that is located at the chemical manufacturing facility. Significant efficiencies are gained from the productive use of the by-product heat, usually in the form of steam. While the efficiency gains can vary widely among individual sites, at its peak co-generation can be over 70 percent efficient.

Electrolytic hydrogen is very pure and it can be used for organic hydrogenation, catalytic reductions, to provide hot flames or protective atmospheres in welding technology, metallurgy or glass manufacture. Hydrogen should be considered a "clean fuel" – meaning it does not emit carbon dioxide, one of the greenhouses gases or other criteria pollutants. Recovering and burning the hydrogen also preserves existing reserves such as coal, oil and natural gas. Considering the vital and growing role of energy in global economic and environmental issues, the chlorine industry is likely to increase its use of co-generation. Because hydrogen is very pure and considered a clean fuel, EPA should classify the cogeneration use of hydrogen fuel as a Gas 1 fuel.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel

specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Comment: Recognition of Pressure-Swing-Adsorption (PSA) Purge Gas as a Clean- Burning Fuel

If the agency retains the distinction between Gas 1 and Gas 2 facilities, defining the term "refinery gas" would prove helpful. Should the agency use the current refinery gas definition as found in the Refinery 1 NESHAP (Part 63 Subpart CC), or a similar version, Air Products wishes to ensure that "clean fuels" produced and/or used by independent entities not connected to a refinery's fuel gas system are recognized and considered by the agency in this ruling. An example of this is the steam methane reforming (SMR) commercial process Air Products and other industrial gas producers use to produce hydrogen, which refiners then utilize to satisfy EPA mandated sulfur reductions in gasoline and diesel fuel production.

In the SMR process, steam and a hydrocarbon feed (usually natural gas (NG) or refinery gas (RG)) are reacted at elevated temperatures over a catalyst in a process heater. The reaction forms a raw product stream comprised of hydrogen (H2), carbon monoxide (CO), and carbon dioxide (CO_2). The H2 is separated from this stream in a pressure-swing-adsorption (PSA) unit. The remaining gas, commonly called PSA purge gas, contains unrecovered H2 as well as the fuel species CO and methane along with up to 50 vol% inerts (mainly CO_2). This low-Btu gas is recycled back to the process heater as the predominant fuel with the remaining fuel balance comprised of NG or RG.

Part of the agency's concerns deal with combustion processes in boilers and process heaters, which promote the formation of carbon radicals that can lead to the generation of hazardous air pollutants (HAPs) as defined by the EPA. This occurs during fuel rich combustion and is readily evidenced by colored flames from the burners. However, when burning PSA purge gas in the SMR process, the flames are typically invisible. Flame shape and sizing are only detectable in the radiation patterns on the process heater walls. The lack of flame color is an indication of excellent combustion, where only the oxidation reaction of CO to CO_2 and H2 to H_2O is primarily occurring. The excellent combustibility (complete combustion) of PSA purge gas has been repeatedly confirmed through CO stack testing of the process heater flue gas, where CO levels are shown to be very minimal through testing via EPA Reference Method 10.

Recommendation: Since SMR PSA purge gas combusts very cleanly, the proposal is for the agency to specifically classify this gas (and others with similar combustion characteristics) as a clean-burning fuel and regulate it accordingly. Otherwise, Air Products estimates at least five of its SMR sources burning this fuel would be subjected to emission limitations, extensive monitoring and possible application of very expensive pollution controls under the proposed rule. It is also recommended that the term "refinery gas" be defined if the distinction between Gas 1 and Gas 2 Facilities remains in the rule.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Commenter Name: Christopher Peters
Commenter Affiliation: Low Carbon Synthetic Fuels Association
Document Control Number: EPA-HQ-OAR-2002-0058-2942.1
Comment Excerpt Number: 2

Comment: The LCSFA believes that EPA did not consider the possibility that syngas could be used in boilers during its rule development process. This is clear because EPA has on numerous occasions recognized the environmental benefits of syngas. Indeed, in the companion rulemaking to the Boiler MACT defining secondary non-hazardous substances that are solid wastes, which informs the distinction between boilers subject to the Boiler MACT and those subject to CAA Section 129 standards for solid waste incineration units, EPA found that producing syngas by gasifying solid wastes would constitute “adequate processing” that could prevent a discarded material from being categorized as a solid waste.[footnote: See Identification of Non-Hazardous Secondary Materials That Are Solid Waste; Proposed Rule, 75 Fed. Reg. 31844, 31878 (June 4, 2010)] There, EPA acknowledged that syngas cleanup “at a minimum involves removal of sulfur and metals” and noted that syngas could be used in a combustion turbine, though it did not mention the possibility of using syngas in boilers.[footnote:Id.]

In addition to the proposed treatment of syngas in the rulemaking defining secondary non-hazardous substances that are solid waste, EPA previously promulgated an exclusion from the definition of solid waste for syngas fuel derived from hazardous waste as long as the syngas met specifications.[footnote: See 40 CFR §261.389(a)(3)] In the Subpart YYYY MACT rule for stationary combustion turbines, EPA similarly recognized the clean properties of syngas and included syngas within the definition of natural gas, noting that for the purposes of that rule, “the definition of natural gas includes similarly constituted fuels such as field gas, refinery gas, and syngas.”[footnote: See 40 CFR §63.6175] (emphasis added) Given that EPA has previously acknowledged the clean properties of syngas and that syngas, refinery gas, and natural gas are all similarly constituted, there is no rational basis for the proposal’s placement of natural gas and refinery gas in the Gas 1 subcategory while placing syngas in the more onerous Gas 2 subcategory.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Commenter Name: Bruce A. Steiner
Commenter Affiliation: American Coke and Coal Chemicals Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2849.1
Comment Excerpt Number: 8

Comment: EPA has proposed the Gas 2 subcategory to encompass all gaseous fuels that are not natural gas or refinery gas. This catch-all subcategory includes landfill gas, coke oven gas, coal-derived gas, biogas, and other process gases. EPA offers no justification for combining these disparate gases into a single subcategory but it may have been driven by a lack of data. With just five sources in the Gas 2 subcategory with dioxin-furan data and just eight sources with data for Hg and HCl, EPA had tied its own hands by not collecting sufficient data to properly distinguish between fuels with significantly different chemical compositions, heating values, and combustion characteristics. EPA's decision to lump these Gas-2 sources together based on what they are not (e.g., because they are not burning natural or refinery gas) is arbitrary and unlawful. Gas 2 fuels are not interchangeable. These gaseous fuels are combusted at or near their point of generation and used to reduce reliance on fossil fuels. Therefore, a Gas 2 source cannot decide to burn landfill gas to help meet the Hg emission standards if they are not in the vicinity of a landfill. Similarly, coke oven gas is only available in the vicinity of coke batteries. Thus, most of the 199 Gas 2 sources cannot use coke oven gas to help meet the dioxin emission limits. Nor does it make environmental or economic sense to displace process gases with natural gas because flammable process gases must be combusted to meet health and safety requirements. Flaring process gases and burning natural gas to reduce emissions at the boiler increases facility-wide emissions, decreases energy independence, and wastes opportunities for energy efficiency. Process gas-fired sources are not candidates for fuel switching.
EPA must, as a result, evaluate and understand the emission characteristics of each process gas fuel to determine if its Gas 2 subcategory is properly defined as a reasonable aggregation of similar sources. EPA has proposed an arbitrary aggregation of dissimilar fuels in the Gas 2 subcategory, which would result in emission limits that are not achievable when burning some process gases even when implementing all available control measures. This should be a strong signal that further subcategorization is warranted prior to the promulgation of the final Boiler MACT rule. If EPA will be setting numeric emission limits for coke oven gas-fired boilers, then these units need a separate subcategory because they have no pathway to attain emission limits established by dissimilar landfill gas and biogas-fired units.

Response: See response to comment EPA-HQ-OAR-2002-0058-2998.1, excerpt 8 for coke oven gas-fired units subcategory.

Commenter Name: Kevin M. Dempsey
Commenter Affiliation: American Iron and Steel Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2998.1
Comment Excerpt Number: 8

Comment: If EPA Decides to Impose Numerical Emission Limits for Gas 2 Fuels, EPA Should Develop a Separate Subcategory for Coke Oven Gas-Fired Units

EPA has proposed the Gas 2 subcategory to encompass all gaseous fuels that are not natural gas or refinery gas. This catch-all subcategory includes landfill gas, coke oven gas, coal-derived gas, biogas, and other process gases. EPA offers no justification for combining these disparate gases into a single subcategory but it may have been driven by a lack of data. With just five sources in the Gas 2 subcategory with dioxinfuran data and just eight sources with data for Hg and HCl, EPA had tied its own hands by not collecting sufficient data to properly distinguish between fuels with significantly different chemical compositions, heating values, and combustion characteristics. EPA's decision to lump these Gas 2 sources together based on what they are not (e.g., because they are not burning natural or refinery gas) is arbitrary and unlawful.

Gas 2 fuels are not interchangeable. These gaseous fuels are combusted at or near their point of generation and used to reduce reliance on fossil fuels. Therefore, a Gas 2 source cannot decide to burn landfill gas to help meet the Hg emission standards if they are not in the vicinity of a landfill. Similarly, coke oven gas is only available in the vicinity of coke batteries. Thus, most of the 199 Gas 2 sources cannot use coke oven gas to help meet the dioxin emission limits. Nor does it make environmental or economic sense to displace process gases with natural gas because flammable process gases must be combusted to meet health and safety requirements. Flaring process gases and burning natural gas to reduce emissions at the boiler increases facility-wide emissions, decreases energy independence, and wastes opportunities for energy efficiency. Process gas-fired sources are not candidates for fuel switching.

EPA must, as a result, evaluate and understand the emission characteristics of each process gas fuel to determine if its Gas 2 subcategory is properly defined as a reasonable aggregation of similar sources. EPA has proposed an arbitrary aggregation of dissimilar fuels in the Gas 2 subcategory, which would result in emission limits that are not achievable when burning some process gases even when implementing all available control measures. This should be a strong signal that further subcategorization is warranted prior to the promulgation of the final Boiler MACT rule. If EPA will be setting numeric emission limits for coke oven gas-fired boilers, then these units need a separate subcategory because they have no pathway to attain emission limits established by dissimilar landfill gas and biogas-fired units.

EPA's current database is insufficient to understand emissions from coke oven gas-fired sources. Of the three units identified in the EPA database as coke oven gas-fired, two have been confirmed as burning petroleum coke, a solid fuel, and not coke oven gas. These data must be excluded from any gaseous fuel analysis. The only remaining emissions data in the EPA dataset for coke oven gas-fired units comes from a source test snapshot of a recovery coke plant in West Virginia that uses a desulfurization system. This limited data from a single source cannot adequately represent the variability inherent in the coke oven gas-fired sources identified by EPA within the Gas 2 subcategory. However, the data can, and do, indicate significant differences between coke oven gas emissions and other Gas 2 process gases. [For a discussion of these differences, we direct you to the comments of the American Petroleum Institute and the National Petrochemical Refiners Association, which reveal significant differences in the emission characteristics among the Gas 2 fuels.]

Response: Based on the revised gas 1 specification definition and data available in the record, EPA expects most of the units that exceed the specification will be firing coke oven gas. Therefore the remaining units in the gas 2 subcategory are more homogeneous than the units included in the proposed gas 2 MACT floor analysis.

See response to comment EPA-HQ-OAR-2002-0048-2632.1, excerpt 19 for inadequacies of the Gas 2 dataset.

Commenter Name: Bruce A. Steiner

Comment Excerpt Number: 10

Comment: To gain a better understanding of the potential risk faced by coke oven gas-fired units under the broad Gas 2 subcategory proposed by EPA, an ACCCI member company conducted stack tests on four coke oven gas-fired boilers in July 2010. The test results confirm that the proposed Gas 2 emission limits for HCl, Hg, and CO are not achievable for these coke oven gas-fired boilers using commercially available emission control technologies. The tests were performed on four identical tangentially-fired industrial boilers. Each boiler has a rated heat input capacity of 650 MMBTU/hour and fires only gaseous fuels, comprised of a mixture of coke oven gas and blast furnace gas with supplementary natural gas, that are supplied to the boilers from common headers for each fuel. Typical fuel gas analyses are provided in (see submittal for Table 1). The boilers operated at 73% to 87% (average 83%) of design heat input capacity during the tests. The average contribution of each fuel to total heat input during the tests was 50% coke oven gas, 39% blast furnace gas and 11% natural gas (see submittal for Table 2).

The test program included the following measurements in each boiler stack:
* Group A:
o CO by EPA Method 10;
o Dioxins and furans by EPA Method 23;
o HCl and filterable non-sulfuric acid PM by EPA Method 26A, combined with EPA Method 5B;
* Group B:
o Mercury and filterable non-sulfuric acid PM by EPA Methods 29 and 101A, combined with EPA Method 5B (modified);
* Stack gas flow rate by EPA Method 2 (all tests); and
* Oxygen, carbon dioxide and moisture concentration by EPA Methods 3A and 4 (all tests).

Three 4-hour test runs were performed on each of the four boilers. Group A and Group B tests were not conducted simultaneously. Tests were performed at approximately the same time of day and under comparable operating conditions. The test methods for CO, Hg, HCl and dioxins/furans are among those specified by EPA for tests conducted under the ICR for this rule and in Table 5 to Subpart DDDDD of Part 63– Performance Testing Requirements of the proposed rule.

Method 5B was selected for filterable PM because it is believed to be a superior surrogate for non-mercury metallic HAPs when sulfuric acid may be present, as discussed elsewhere in these comments. Sulfur dioxide (SO2) concentrations in the exhaust gas indicate that sulfuric acid may be present at concentrations on the order of 5- 7 ppmv, which represents a potentially large fraction of the proposed filterable PM limit (on a lb/MMBTU basis). Method 5B is designed to mitigate the effect of sulfuric acid on the filterable PM results, which allows for a more accurate surrogate for non-mercury metallic HAP. For the Method 29 and Method 101A tests, filterable PM samples were collected with the probe and filter temperature at 160°C as specified in Method 5B, but the laboratory analysis was modified by drying the samples in a desiccator at room temperature as specified in Methods 29 and 101A rather than in an oven at 160°C as specified in Method 5B, so that Hg was preserved in these samples. For the Method 26A tests, Method 5B was performed normally.

The test results show highly variable CO emissions with an average concentration 28 times higher than the proposed limit. Also, HCl and Hg values exceed the proposed limits by more than an order of magnitude (see submittal for Table 3 and Figure 1) rendering them unachievable. Highly variable CO results among the four identical units were not unexpected due to the presence of blast furnace gas in the fuel mix,4 the nature of these low BTU fuels, and normal variations in boiler operations even at a relatively constant total heat input near design capacity. These short duration tests cannot capture the full range of normal operating conditions that might be experienced over several years. However, they are important indications that coke oven gas-fired units are significantly different from other Gas 2 units and that further data and analysis are needed before setting numeric emission limits for coke oven gas-fired units.

The levels of HCl, Hg, and CO exceed the proposed Gas 2 limits by such a large margin that available emission control measures would be insufficient to achieve the proposed Gas 2 limits. If optimistic assumptions for control efficiency are applied to the uncontrolled levels measured in these tests, it is clear that the Gas 2 emission limits cannot be reliably achieved (see submittal for Table 4). Even assuming 99% HCl removal, the proposed Gas 2 limits could not be achieved. This control efficiency is very optimistic given the

[Footnote 3: The test method for dioxins/furans was left blank in Table 5 of the proposed rule. EPA should correct this oversight in the final rule. We assume that Method 23 is the intended method for these compounds based on the preamble discussion at 75 Fed. Reg. 32013.]

[Footnote 4: Blast Furnace Gas contains large amounts of carbon monoxide and no organic HAP, thus the presence of CO in the exhaust gas from BFG fuel mixtures may not be an indication of the presence of organic HAP. The highest CO was observed during tests on Boiler 12, which is attributed to the higher relative contribution of blast furnace gas at that boiler.]

Response: See response to comment EPA-HQ-OAR-2002-0058-2998.1, excerpt 8 for coke oven gas-fired units subcategory.

Comment Excerpt Number: 11

Comment: In the past six years, PCA invested over $24 miJIion (unsubsidized) to build anaerobic reactors and biogas collection, conditioning and combustion systems to develop renewable energy sources at two of our pulp and paper operating locations. As mentioned earlier, two of our company boilers are classified as "Other Gas" boilers. In both cases, the boilers in question combust biogas collected from facility anaerobic wastewater treatment reactors, Biogenic gas and natural gas, as fired, are essentially one in the same aside from the fact that biogenic gas contains a dead load of carbon dioxide. Under the proposed rule, both of our biogas-fired boilers are subject to the "Other Gas" subcategory emission limits. We estimate that our compliance cost for these two units will exceed $30 million in capital and an additional $2 million per year in operating costs. The estimated compliance cost of the proposed rule exceeds the capital cost of constructing these renewable energy projects by 50 percent. The proposed rule effectively penalizes innovative renewable energy investment and discourages any consideration for further implementation or expansion of those kinds of projects.
Biogas fuel produced from anaerobic wastewater treatment plants should be classified in the natural/refinerygas subcategory.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Comment Excerpt Number: 14

Comment: The proposed "Gas-2" subcategory would encompass all gaseous fuels that are not natural gas or refinery gas. This catch-all subcategory includes landfill gas, coke oven gas, coal-derived gas, biogas, and unidentified "other" process gases. While EPA offers no justification for combining these disparate gases into a single subcategory, it may have been driven by a lack of data. With just five sources in the Gas-2 subcategory with dioxin-furan data and just eight sources with data for mercury and HC1, EPA tied its own hands by failing to collect sufficient data to distinguish between fuels with significantly different chemical compositions, heating

values and combustion characteristics. EPA's decision to lump these Gas-2 sources together based on what they are not (i.e., not natural or refinery gas) is arbitrary and unlawful.
Gas-2 fuels are not interchangeable. Gas-2 fuels are combusted at or near where they are generated and used to reduce reliance on fossil fuels. Therefore, a boiler burning coke oven gas cannot choose to burn landfill gas to achieve the mercury emission standards set by landfill gas-fired boilers if they are not in the vicinity of a landfill. Similarly, coke oven gas is only available to boilers and process heaters operating in the vicinity of coke batteries and most of the 199 Gas-2 sources cannot choose to burn COG to help meet dioxin emission limits. Nor does it make environmental or economic sense to displace Gas-2 process gases with natural gas, as discussed above, because flammable process gases must be combusted to meet health and safety requirements. Flaring process gases and burning natural gas to reduce emissions at the boiler increases facility-wide emissions, decreases energy independence, and wastes opportunities for energy efficiency. Gas-2 sources are not similar units that can adjust their fuels to those used to establish the MACT floor emission limit for the subcategory.
EPA must evaluate and understand the emission characteristics of each process gas fuel to determine if the Gas-2 subcategory is properly defined as a reasonable aggregation of similar sources. The current proposal to arbitrarily aggregate dissimilar fuels in the Gas-2 subcategory would result in emission limits that are not achievable when burning coke oven gas - even when implementing all available control measures. This is a powerful signal that further subcategorization is necessary prior to the promulgation of the final Boiler MACT rule. If EPA decides to set numeric emission limits for coke oven gas-fired boilers, then these units need a separate subcategory because they have no pathway to attain emission limits established by dissimilar landfill gas and biogas-fired units.
EPA's current database is insufficient to understand emissions from coke oven gas-fired sources. Of the three units identified in the ICR database as COG-fired, two have been confirmed as burning petroleum coke, a solid fuel, and not coke oven gas. These data must be excluded from any gaseous fuel analysis. The only remaining emissions data in the EPA dataset for COG-fired units comes from a source test snapshot of a byproducts recovery coke plant in West Virginia that uses a desulfurization system. This limited data from a single source cannot adequately represent the variability inherent in the COG-fired sources identified by EPA within the Gas-2 subcategory. However, the data can, and do, indicate significant differences between COG emissions and other Gas-2 process gases. [Footnote: For a discussion of these differences, we direct you to the comments of the American Petroleum Institute and the National Petrochemical Refiners Association, which reveal significant differences in the emission characteristics among the Gas-2 fuels.]

Response: See response to comment EPA-HQ-OAR-2002-0048-2632.1, excerpt 19 for inadequacies of the Gas 2 dataset.
See response to comment EPA-HQ-OAR-2002-0058-2998.1, excerpt 8 for coke oven gas-fired units subcategory.

Comment Excerpt Number: 16

Comment: Based on this analysis, it is technically infeasible for coke oven gas-fired boilers to achieve the proposed Gas-2 emission limits. Therefore, if EPA imposes numerical emission limits on coke oven gas-fired units despite our prior objections, the Agency must develop a separate subcategory for coke oven gas-fired units which has limits that are achievable based on the unique chemical composition and emission profile of that process gas.

Response: See response to comment EPA-HQ-OAR-2002-0058-2998.1, excerpt 8 for coke oven gas-fired units subcategory.

Commenter Name: Chris Korleski
Commenter Affiliation: Ohio EPA
Document Control Number: EPA-HQ-OAR-2002-0058-2818.1
Comment Excerpt Number: 30

Comment: The US EPA should also consider separately or clearly define the treatment of gaseous fuels derived from biomass. Such fuels generated by bio-digester systems, wastewater treatment plants, and landfills are currently fired in boilers and likely to grow in future use. Depending on the source, the fuel is likely to contain chlorine or mercury and likely to have constituents that can lead to the formation of dioxins and furans.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for expansion of gas 1 definition and finalized work practice standards for all gaseous fuel boilers meeting the specifications for hydrogen sulfide and mercury. Based on the data in the record available for biogases most of these units fall below the specification and thus this revised definition should provide more flexibility to units burning these altnerative gaseous fuels.

Commenter Name: Kevin M. Dempsey

Document Control Number: EPA-HQ-OAR-2002-0058-2998.1
Comment Excerpt Number: 32

Comment: We also note that there is very little difference between the emissions from the top performing sources in the Gas 2 subcategory as compared with the Gas 1 subcategory. As a result, in the alternative to further subcategorization of Gas 2 units as described below for coke oven gas-fired units, EPA would be justified in concluding that the Gas 1 and Gas 2 subcategories should be combined into a single gas-fired subcategory, which would be regulated by work practice standards for the reasons EPA explains in the preamble. At a minimum, units fired with process gases generated in chemical plants, pulp and paper plants, iron and steel plants, and similar operations should be included in the Gas 1 subcategory because the emissions data show very little difference in performance between units at these facilities and Gas 1 units.

Response: We appreciate the input from the commenter. EPA has modified the definition of gas 1 and adopted a fuel specification. See the preamble for detailed discussion of the fuel specification. We are not finalizing limits for units firing natural gas, refinery gas, and other Gas 1 fuels. See preamble for rationale for selecting a work practice for these units.

Subcategories: Biomass: Dutch Oven/Susp Burner

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 151

Comment: Dutch ovens and suspension burners are fundamentally different in design and fuel firing capabilities. Dutch ovens have two chambers. Solid fuel is dropped down into a refractory lined chamber where drying and gasification take place in the fuel pile. Gases pass over a wall into the second chamber where combustion is completed. Dutch ovens are capable of burning high moisture fuels such as bark, but have low thermal efficiency and are unable to respond rapidly to changes in steam demand. Suspension burners combust fine, dry fuels such as sawdust and sanderdust in suspension. Rapid changes in combustion rate are possible with this firing method. They can be of watertube or firetube design, and may be package units or field-erected. It is not appropriate to combine these two types of boilers given their much different characteristics, and a subcategory should be established for each.
In the Phase I survey database for major sources with boilers, a “True” in the Dutch oven column appears for 24 boilers. However, 13 of the installation dates are more recent than 1960, making it unlikely these are really of the Dutch oven design. Regarding suspension burners, it is very difficult to use the survey database to identify true suspension burners. Many biomass boilers indicating fuels are burned in suspension are actually stokers or fluidized beds where a small portion of the fuel may be fed to the boiler and burned in suspension. We suspect there are fewer than 30 of units that burn all of the biomass fuel in suspension. They would mainly be located at particleboard, hardboard, and medium density fiberboard plants that have fine dry fuels available.
The ERG April 26, 2010 MACT floor memo shows 17 units with CO tests in the Dutch oven/suspension burner biomass subcategory. Only two of these appear to be true Dutch ovens:
* WAGraysHarborPaper No. 6 Boiler
* ORRosboroSpringfield DV 01.1
The following appear to be suspension burners:
* TXDibollTemple-Inland PB-44
* ORFlakeboardEugene Boiler-2

* OHSauderWoodArchbold B008, B009
* MNNorbordMinnesota Konus No. 1 and 2 (process heaters).

Response: EPA has revised the definitions and separated this category into hybrid suspension grate boilers and process heaters, which fire high moisture fuel, predominantly bagasse. The remainder of the units in the dutch oven and suspension burner subcategory are firing blended biomass with similar CO emissions and PM emisisons and none of the remaining suspension burners had THC data available. EPA based the subcategorization on the reported classifications of each boiler in addition to any corrections received during the public comment period.

Commenter Name: David A. Buff
Commenter Affiliation: Golder Associates Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2801.1
Comment Excerpt Number: 8

Comment: However, EPA has inappropriately subcategorized suspension burners/dutch ovens designed to burn biomass as a single subcategory. Dutch ovens are much different in design and operation than suspension burners, and should be in a separate subcategory. Also, there are suspension burners that burn all their fuel in suspension and have no grate. These boilers burn dry fuel that can be combusted totally in suspension. Emissions of organic HAPs and PM from these type boilers are much different than boilers that must utilize a combination of suspension firing and grate firing in order to properly and totally combust a wet fuel. Therefore, EPA should set separate subcategories for organic HAPs (or CO) and for metal HAPs and PM for:

* Bagasse boilers (48 to 55 percent moisture)

* Suspension burners designed to burn dry biomass (<30 percent moisture),

* Suspension burners designed to burn wet biomass (>30 percent moisture)

* Dutch ovens

The bagasse the FSl burns in its boilers always has between 48 percent and 55 percent moisture. This high level of moisture is dictated by the sugar cane grinding and washing process. The boilers are designed as hybrid suspension/grate-floor burners in which the wet fuel first undergoes drying and then combustion in suspension within the furnace, with any remaining unburned fuel falling onto the grate to complete combustion.

However, boilers burning dry biomass (i.e., <20 to 30 percent moisture fuel) do not need to undergo this initial drying process, since the fuel is already dry enough to combust when it enters the boiler. Excess air levels can be decreased and combustion efficiency improves. Thus, suspension burners burning dry biomass can be and are designed differently, and are operated differently, than suspension/floor-grate burners burning wet biomass.

Response: See preamble for a new hybrid suspension/grate burner category and response to comment EPA-HQ-OAR-2002-0058-3213.1, excerpt 151 for the modifications made to the dutch oven/suspension burner subcategory.

Subcategories: Biomass: Stoker/Sloped Grate

Commenter Name: Michael L. Steele
Commenter Affiliation: CraftMaster Manufacturing, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-1907.1
Comment Excerpt Number: 3

Comment: An example of a questionable categorization is CraftMasters No3Boilerthatfiresbiomass through a combination of Air-swept Stokers (14% of heat input in 2009), Suspension Burners (70%), and natural gas (16%). Suspension Burners used by CraftMaster are similar to pulverized coal burners.

Per the "Inventory of Major Source Boilers and Process Heaterstl database, USEPA has placed the N03 Boiler in the "Stoker/Sloped Gate/Other" combustor design category. It is assumed this is the same as the "Stoker" subcategory. It is clear that the No3 Boiler does not have mechanical stokers and the air-swept stokers (defined as Suspension Boiler in proposed regulations) provided only 14% of the heat input in 2009. The primary firing method is the suspension burners with 700/0 of the heat input. Then the primary firing method used is apparently not considered by USEPA in establishing what subcategory a unit is in.

To summarize, USEPA appears to have an excessive number of subcategories for biomass-fired units without proper definition. Many units could be classified in the incorrect subcategory including those in the MACT Floor. It is suggested that these issues be investigated with intent of possibly reducing the number of biomass subcategories. This would alleviate the confusion associated with the lack of definitions, etc. Also, the number of units included in the MACT Floor would be increased and associated issues would be reduced as well.

Response: See the final rule for revised definitions of each combustor design. EPA established a hierarchy for assinging each combustor designs as described in the memorandum "Revised Development of Baseline Emission Factors for Boilers and Process Heaters at Commercial, Industrial, and Institutional Facilities". It did not determine the heat input provided through each separate combustor design due to limited data provided in the survey with respect to the heat input channelled through separate combustor designs.

Subcategories: Biomass: Fluidized Bed

Commenter Name: Michael L. Steele
Commenter Affiliation: CraftMaster Manufacturing, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-1907.1
Comment Excerpt Number: 27

Comment: Combustor-based Limits

Wouldn't combustor design have an impact on HCl emissions if a Fluid bed was using limestone media? Are there any units like this in the HCl MACT Floors? If so, they should be evaluated as a possible subcategory.

Response: EPA determined that HCl emissions are more influenced by fuel type instead of combustor design. For the solid fuel units that are the floor there are various combustor design types including fluidized beds.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 28

Comment: NACAA agrees that fluidized bed combustion units (either biomass or coal-fired) are of sufficiently different design and anticipated performance that a separate subcategory may be warranted, but does not see a justification for the other subcategories proposed by EPA for the Boiler MACT rule.

Response: EPA agrees with the commenter about separate subcategory for fluidized beds. However, EPA also maintains that the other subcategories are appropriate for organic HAP in addition to new categories for non-continental, hybrid suspension-grate burners, and limited use units. See the final rule for discussion of new categories.

Subcategories: Biomass: Fuel Cell

Commenter Name: Arthur N. Marin
Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 17

Comment: NESCAUM also recommends eliminating the proposed "fuel cell" subcategory for wood-fired boilers in the MACT rule. A fuel cell is generally understood to create electricity directly from a fuel gas without combustion.1 As such, a true fuel cell would not be subject to the ICI boiler rule. One does not find in the technical literature a discussion of “fuel cell” combustion units. The units in EPA’s database that it styles as “fuel cell” units appear to be newer than most, and for that reason, relatively fuel efficient and low-emitting, but there does not appear to be any difference in fundamental design that would warrant establishment of a separate category.

Response: See response to comment EPA-HQ-OAR-2002-0058-2841.1, excerpt 26.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 26

Comment: The “fuel cell” subcategory of wood-fired boilers is especially problematic. A fuel cell is generally understood to create electricity directly from a fuel gas without combustion.[58 See, e.g., Standard Handbook of Powerplant Engineering, Section 8.6, Elliot (ed), McGraw Hill, 1998.] As such, a true fuel cell would not be subject to the ICI Boiler Rule. One does not find in the technical literature a discussion of “fuel cell” combustion units. A visit to the website of one of the manufacturers of a unit (Wellon, Inc) that EPA asserts is a wood-fired fuel cell combustion unit reveals that the company does refer to certain of its units as fuel cells, but this reference is to a marketing approach to the sale of modular units, rather than a particular design.[The company will sell a fuel cell that is either top-fired or bottom-fired.] The units in EPA’s database that it styles as “fuel cell” units appear to be newer than most, and for that reason, relatively fuel efficient and low emitting, but there does not appear to be any difference in fundamental design that would warrant establishment of a separate category.

Creating larger numbers of subcategories usually leads to higher MACT floors in two ways. First, if a small number of the best performers (e.g., fuel cells) can be culled from a larger group into their own subcategory, the MACT floor for the larger group (the wood-fired boilers) will rise. Second, because the small group will have a small number of tests, the statistical variability of the small group will also increase, leading to MACT floor increases for both the larger group and the smaller group.[EPA’s proposed MACT standards for wood-fired boilers are identical for all pollutants except CO.]

Response: EPA disagrees with removing the fuel cell subcategory. This combustor type was a unique option that could be selected in the ICR survey. The ICR survey received a separate public comment period and the fuel cell category was not disputed during the time of the survey.

Subcategories: Coal: Fluidized Bed

Commenter Name: Robin Mills Ridgway
Commenter Affiliation: Purdue University
Document Control Number: EPA-HQ-OAR-2002-0058-2782.1
Comment Excerpt Number: 2

Comment: Due to the nature of CFB technology, the ability to combustion optimize (or "tune") the boiler to minimize CO emissions is extremely limited in comparison to pulverized and stoker firing technologies. In CFB combustion technology there is a directly inverse relationship between CO emissions and NOx emissions. As the furnace temperature is raised to enhance carbon burn out and decrease CO emissions, NOx emissions increase. NOx emissions in a CFB boiler are inherently low due to the low temperature combustion in the furnace.

CO emissions increase and become less consistent at higher loads for a stoker fired boiler whereas CO emissions increase at lower loads for the CFB fired boiler. This difference in performance has to do with many factors that are unique to the combustion technology and unit design. The increase in CO emissions at lower loads for the CFB has to do with thermal stratification in the furnace whereas the increase in CO for a stoker fired or pulverized coal boiler has to do with combustion residence time.

[See submittal for graph showing Boiler 5 CO & NOx emissions versus bed temperature.]

[See submittal for graph showing Boiler 5 CO emissions versus load.]

Response: See the preamble for a discussion of how CO limits were modified.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 27

Comment: NACAA agrees that fluidized bed combustion units (either biomass or coal-fired) are of sufficiently different design and anticipated performance that a separate subcategory may be warranted, but does not see a justification for the other subcategories proposed by EPA for the Boiler MACT rule.

Response: EPA agrees with the commenter on maintaining a separate subcategory for fluidized bed boilers but disagrees that other combustor designs are not relevant.

Comment: When the court vacated the earlier ICI Boiler MACT rule and state and local permit authorities were faced with developing case-by-case MACT permits, NACAA collected existing test data from over 40 state and local permitting agencies, including hundreds of data points that NACAA used to calculate MACT floors, which were substantially lower than those adopted by EPA in its earlier rule. The NACAA database was provided to EPA in June of 2009.
Many units combust mixtures of fuels.
When switching fuels, emissions of one HAP may increase while those of another HAP may decrease without clear correlation. In its model permit guidance, NACAA considered only those results where a source was burning 100 percent of one category of fuel during the test.
Under NACAA's recommended approach, sources would be separately tested for compliance with each applicable limit. NACAA also noted that during compliance testing, sources may be able to establish unit-specific correlations for operation of different fuels.
EPA apparently did not use any of the testing in the NACAA database to establish the MACT floors. The EPA data includes numerous entries where a source was combusting different fuels, which NACAA believes will be difficult to translate into enforceable MACT limitations.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: The proposed rules specify that a unit fired on just over 10% biomass and just under 900/0 natural gas, is considered a biomass unit. Is the same criteria used for units in the biomass MACT Floors? If so, such a unit should not be in the biomass MACT Floor. The Floor for biomass should be based on all-biomass fired or substantially so. If not, how can an aH-biomass fired unit comply with a MACT limit derived from data that includes essentially gas-fired units?

Response: See the preamble for response to the pollutant-by-pollutant approach and achievability of standards as well as response to how the subcategories and thresholds were adjusted in the final rule to better accommodate combination fuel boilers.

Comment: How are multiple fuels handled when one fuel is in one subcategory (say biomass) and another is in another subcategory (say natural gas)? How is test data affected? F factor for combined fuels or just fuel associated with subcategory we’re testing compliance for? What other implications are there in the proposed rules?

Response: The preamble final rule outlines the annual heat input thresholds that define what subcategory a unit belongs to. To determine compliance with the emission limits, you must use the F-Factor methodology and equations in sections 12.2 and 12.3 of EPA Method 19 at 40 CFR part 60.

Comment: When the court vacated the earlier ICI Boiler MACT rule and state and local permit authorities were faced with developing case-by-case MACT permits, NACAA collected existing test data from state and local permitting agencies. Over 40 agencies provided hundreds of data points that NACAA used to calculate MACT floors, which were substantially lower than those adopted by EPA in its earlier rule. The NACAA database was provided to EPA in June of 2009.

Many units combust mixtures of fuels. No clear correlation has been established to evaluate the emissions performance of different units combusting different mixtures of fuels –-and indeed, when switching fuels, emissions of one HAP may increase while those of another HAP may decrease. In its model permit guidance NACAA considered only those results where a source was burning 100 percent of one category of fuel during the test. Under NACAA’s recommended approach, sources would be separately tested for compliance with each applicable limit. NACAA also noted that during compliance testing, sources may be able to establish unit-specific correlations for operation of different fuels.

EPA apparently did not use the testing in the NACAA database to establish the MACT floors. The EPA data includes numerous entries where a source was combusting different fuel mixes, which NACAA believes will be difficult to translate into enforceable MACT limitations.

EPA’s approach is to categorize source categories according to fuels that they are designed to combust and allow sources to comply with what EPA apparently considers the least stringent standard for any of the fuels that it may combust. NACAA believes that this approach is likely to be unworkable for many sources.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: EPA must adjust the proposed subcategories to properly accommodate the unique characteristics of combination boilers.
Within certain industry sectors, boilers are commonly used that co-fire coal in an amount greater than 10% heat input basis with at least 10% biomass. These "combination boilers" that simultaneously burn coal and biomass have different emission profiles than units that burn coal or units that burn biomass. As a result, combination boilers do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA adjust the proposed subcategory for combination boilers so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and mercury) and the biomass subcategory for purposes of regulating the combustion-based HAP (i.e., CO (as a surrogate for organic HAPs) and dioxins/furans).

As the rule is currently proposed, boilers that burn more than 10% coal with biomass will be classified in the coal subcategory; however, most such boilers will not be able to meet the coal subcategory CO emission standard for organic HAPs due to the substantial amount of biomass that they burn. Biomass fuels are more variable than coal and typically contain significantly more moisture than coal. As a result, it is more difficult to control combustion conditions in combination boilers than in boilers combusting only coal, which means that CO emissions from combination boilers often will be unavoidably greater than from a comparable coal-fired boiler. This makes the coal subcategory an inappropriate choice for establishing standards for combustion-based HAP. Regulating combustion-based HAP from combination boilers under the biomass subcategory makes more sense because combination boilers will perform more like biomass-fired boilers with regard to the combustion related HAPs.

On the other hand, biomass typically has lower levels of metals, halogens, and mercury than coal. As a result, regulating the fuel-related HAPs from combination boilers under the biomass subcategory would be inappropriate because the amount of co-fired coal would in many cases prevent combination boilers from meeting the standards for fuel-based HAPs. For this reason, it makes more sense to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: Co-firing Fuels. The Maine Mills have concerns with the proposed unit subcategories with respect to units that burn multiple fuels. Certain boilers at the Mills burn greater than 10% fossil fuel on an annual basis; however, the units also burn a significant amount of biomass, including periods of 100% biomass. For some pollutants such as CO, the emissions profile is much different based on the fuel mix with higher emissions expected from burning biomass. Likewise, the proposed limit for CO for the coal subcategory is much lower than the proposed limit for the biomass subcategory; however, the unit would be restricted to meet only the lower coal limit, because it fires greater than 10% on an annual basis. EPA needs to consider alternate CO and dioxin/furan limits for sources that co-fire fossil fuels and biomass fuels.

Comment: A Pollutant-by-Pollutant Approach is Not Appropriate for Our Boilers

The air emissions profile of the many multi-fuel-fired boilers in the pulp and paper industry varies with fuel mix, making it difficult to establish a "typical" emissions profile. Many times boiler operators have emission limits that change based on the fuel fired. The fact that these boilers must often adapt quickly to varying process steam demand and experience frequent load swings also makes characterizing "typical" emissions difficult. Permitting changes to a multi-fuel fired boiler is challenging because predicting projected actual emissions following the change is difficult, as fuel mix can vary based on season, fuel cost, and operation of other equipment at the facility.
Air emissions control studies for multi-fuel-fired boilers can be difficult, as the control strategy and primary compound of concern vary with the fuel mix. Consider a pulp and paper mill boiler that burns fuel oil, biomass, and coal. Coal and biomass might produce the highest particulate emissions, but coal and fuel oil produce the highest SO2 and HCl emissions, and biomass may produce the highest CO emissions. Therefore, an ESP might be the most appropriate control device for wood firing, a wet scrubber might be the most appropriate control device for coal and oil firing, and control options like combustion improvements would have to be evaluated to reduce CO emissions from wood firing. It is our hope that future CO, VOC, and HAP limits are not so low that combustion improvements alone will not be enough to achieve compliance, as there are no reasonable add-on emissions control combinations for these compounds that make sense to implement on our boilers. For example, adding catalytic oxidation, considered by EPA as appropriate under this proposal, does not materially affect HAP emissions unless flue gas temperatures are at least 400°F. The use of CO catalysts as HAP control therefore requires reheating flue gases by 100°F or more, as they cannot likely be situated prior to particulate control devices. CO catalysts will also oxidize SO2 to SO3 and NO to NO2. This outcome is not practical, since it increases emissions, reduces efficiency, and moves away from both environmental and energy security objectives.

Under the proposed Boiler MACT regulation, the emission limits for each compound have been developed based on the best performing boilers for each compound, not the best overall performing boilers of each boiler type subcategory. Therefore, the boiler may have to install multiple emissions controls to account for the fact that it burns multiple fuels, each with a different emissions profile, and meet multiple fuel-based emission limits for multiple rules (MACT, NSPS, state regulations, and lower NAAQS). It is appropriate to consider multi-fuel-fired boilers differently than single fuel boilers in the context of boiler emissions regulations.

Comment: For combination fuel boilers where biomass is routinely a large portion of the fuel heat input but coal is the regulated fuel subcategory, EPA defines the coal subcategory in this rule to be when coal makes up at least 10% of the heat input, the proposed CO limit inadvertently incents increasing the proportion of coal heat input to more easily comply with the standard.

Comment: EPA's Stated Bases for its Proposed Subcategories is Unsupported by the Data, and Internally Inconsistent, and Therefore Unreasonable and Arbitrary.

EPA's preamble statements and a brief discussion in the memorandum describing the floor setting exercise [See submittal for Reference 2.] are the only justification for its subcategories provided by the Agency in the record for this rule. Indeed, the supporting material for the information request underlying the rule simply assumes the continued use of the five subcategories for new and existing boilers as used in the 2004 rule, which the agency states are: "units designed to burn coal, units designed to burn biomass, units designed to burn liquid, units designed to burn natural gas/refinery gas, units designed to burn other process gases." Supporting Statement, Information Collection Request, NESHAP for Industrial, Commercial and Institutional Process Heaters, EPA-HQ-OAR2002-0058-0801, at 1.

A review of the few limited statements that are in the record for the proposal demonstrates that the arguments EPA puts forward to support its subcategories are themselves internally inconsistent, and unreasonable. For example, EPA asserts it has chosen fuel-based subcategories for what it calls the "fuel-dependent HAPs" – mercury, acid gases, and non-mercury metallic HAPs – because "data indicate that there are significant design and operational differences between units that burn coal, biomass, liquid, and gaseous fuels. Boiler systems are designed for specific fuel types and will encounter problems if a fuel with characteristics other than those originally specified is fired." 75 Fed. Reg. 32,017 (emphasis added). At the same time, however, when defining the various subcategories, EPA states, for example, that "if your new or existing boiler or process heater burns at least 10 percent coal on an annual average heat input basis, the unit is in one of the coal subcategories." Id. 32,012. This 10 percent rule or a variant of it defines all the fuel-based subcategories EPA uses. But a unit that burns, say, 12 percent coal is burning 88 percent something else, by definition. So, the HAPs it emits are would seem as or more likely to be dependent on the 88 percent of non-coal fuel being burned. And, if EPA's design and operational justifications (that boiler design and operation is very specific to fuel type) are correct, a unit burning 10 percent coal and 90 percent of some other fuel, which EPA's subcategories define as a "coal-fired" unit, should regularly "encounter problems." EPA nowhere explains this inconsistency -- either EPA's statements about the fuel-specific nature of boiler design and operation are not correct, or EPA has proposed MACT standards that will apply to boilers that by their nature are "encountering problems" due to their fuel mix.

Response: Please refer to the preamble for discussion of combination fuel units. See final rule and preamble for discussion of how units are assigned to subcategories and provisions available to switch subcategories.

Comment: While the MACT floors are calculated based on the fuel consumed during the test, the EPA section 112 proposal sets out a different test for determining which limit would apply to a particular unit in the future. EPA calls this test a "designed to combust" test, asserting that the limits will apply depending on the nature of the fuel that a unit is designed to combust. However, any unit that burns a fuel must be "designed" to combust that fuel and units that combust multiple fuels are, in fact, designed to combust each of those fuels. Under the proposal, the applicability of different limits is based on whether a source has combusted a prescribed amount of a type of fuel, not necessarily the fuel it combusts during a compliance test, and not the fuel that might be expected to dominate its current emissions profile. Thus, a unit would be "designed to combust" coal if at some unspecified time it generated at least 10 percent of its annual heat input from coal. EPA's proposal continues with a tiered system where, if the source did not burn 10 percent coal, it would look to see if it burned more than 10 percent biomass, and if it did, it would be subject to the biomass limits. If a source burned less than 10 percent solid fuel and any liquid fuel at all, it would be subject to the limits for liquid-fired units (even if it obtained 99.9 percent of its heat input from natural gas). Under this scheme a unit would be a coal-fired unit,[The proposal does not set out how the percentage of annual heat input is to be determined, but sources will need to know in advance of the commencement of a given year which limits apply to operations during that year] subject to the emission limitations based on the emission profile of coal-burning units, even if today it is burning 100 percent biomass. This would result in a situation where the CO limit is unattainable at the source, while the mercury and hydrogen chloride (HCl) limits are overly lax. This scheme also unfairly affects those who co-fire natural gas and oil, since the combustion of any oil at all would remove the exemption from emission limitations that EPA proposes for natural gas-fired units.

The proposal does not set out a rationale for this new approach or why the procedures set out in the vacated rule to address fuel mixtures are inadequate. NACAA recommends that MACT limits be established for each major category of fuels and that the procedures found at 40 CFR 63.7530 be used to address fuel mixtures.

Comment: With respect to the degree to which units can fuel-switch between liquid and gaseous fuels or between such fuels and solid fuels, EPA strings several conflicting sentences together in the preamble that belie the conclusion it reaches that changing fuel type requires extensive changes to boiler systems. The Agency says "[w]hile many boilers in the population data base are indicated to co-fire liquids or gases with solid fuels, in actuality most of these commonly use fuel oil or natural gas as a startup fuel only, and operate on solid fuel during the remainder of their operation. In contrast, some co-fired units are specifically designed to fire combinations of solids, liquids, and gases." 75 Fed. Reg. 32,017. Data in the floors memorandum, by contrast shows that "many boilers and process heaters are designed to burn multiple fuel types," indeed, "some units reported test burns on more than one material" including the switch between tests between gas and liquid fuels (burned during periods of 'gas curtailment'). Floor Memo at 4. Clearly the distinction between boiler types on the basis of fuels burned, viewed in the best light possible, is not as dramatic as EPA describes – it certainly does not justify EPA's choice of subcategories. EPA's rationale is substantively empty, and therefore unreasonable. Moreover, that fact suggests EPA's real motivation – to define subcategories not by "class, type, and size" as the statute requires, but so that the resulting MACT floors are achievable by the majority of ICIBPH. That rationale is unlawful.

Response: Please refer to the preamble for discussion of combination fuel units. See final rule and preamble for discussion of how units are assigned to subcategories and provisions available to switch subcategories.

Comment: EPA must adjust the proposed subcategories to properly accommodate the unique characteristics of combination boilers. Both of our cogeneration boilers co-fire coal in an amount greater than 10% heat input basis with greater than 10% biomass. As a result, they do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA create another subcategory so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and mercury) and the biomass subcategory for purposes of regulating the combustion-based HAP (i.e., CO (as a surrogate for organic HAPs) and dioxins/furans).

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 10

Comment: The proposed definition of any boiler burning at least 10% coal is a coal-fired boiler results in non-representative emission standards and is unfair to boilers predominantly fired with coal.

EPA has arbitrarily decided to categorize combination type boilers that burn at least 10 percent coal as a coal-fired boiler. They then included emission data from such boilers along with 100 percent coal-fired boilers to establish standards for new and existing sources. This is inherently unfair to both biomass and coal fired boilers. Coal-fired boilers will inherently have higher emissions of HCl and mercury whereas biomass boilers will inherently have higher CO emissions. Eastman recommends EPA reverse its methodology and only use data from boilers burning at least 90 percent coal to set standards for the coal subcategories and to use data from boilers burning less than 10 percent coal to set standards for the biomass subcategories. For combination boilers, EPA should allow compliance to be determined using weighted averages such as in NSPS Db where EPA used this methodology for sulfur dioxide and NOx. We do not see any issues related to enforceability of such weighted average standards that cannot be overcome with today’s information technology.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Sharene Shealey
Commenter Affiliation: RRI Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2759.1
Comment Excerpt Number: 10

Comment: EPA must clarify whether the definitions for boiler subcategories are based on actual fuel firing or permitted fuel firing and over what time period the annual average should be taken.

RRI Energy owns and/or operates several ICI boilers that are capable of and permitted to burn multiple fuels, generally fuel oil or natural gas. In all cases where units are permitted to burn two fuels, the units typically only fire one fuel. For example, the auxiliary boilers at Conemaugh Station, Aux Boiler A and Aux Boiler B, are permitted to burn either No. 2 Fuel Oil or Natural Gas. Aux Boiler B was installed in 2006 and only fired fuel oil during the start-up/shakedown and testing phase of operation, all of which occurred in 2006. This boiler has not since fired fuel oil; in practice it is a natural gas-fired boiler. In 2006 though, because of start-up/shakedown and required testing, 14.8% of this boiler's heat input was due to fuel oil firing. This boiler has not combusted any fuel other than natural gas since start-up was completed. RRI Energy considers this boiler to be gas-fired, and believes it should be regulated as such. We are requesting that EPA clarify whether the actual practice or permit conditions define the fuel and we request clarification on the use of the term "annual average".

RRI strongly believes that practice should dictate the boiler's subcategory and that at least two years of data be included in determining the annual average fuel contributions.

Response: See the preamble and final rule for modified provisions available to switch between subcategories. In the final rule the term 'heat input on an annual average' contained within each of the subcategories was switched to 'annual heat input'.

Commenter Name: Robert R. Scott
Commenter Affiliation: New Hampshire Department of Environmental Services, Air Resources Division
Document Control Number: EPA-HQ-OAR-2002-0058-2734.1
Comment Excerpt Number: 11

Comment: NHDES also considers the approach of categorizing boilers based on one primary fuel type to be problematic for enforceability. Boilers today are often configured to run on multiple fuels and the percentage of any one particular fuel over another can be based in part on the cost of each fuel. Therefore, a boiler that would be considered part of one sub-category based on the previous year's annual heat input could be operating under an entirely different fuel loading scenario the following year. Also, without detailed requirements for tracking, recordkeeping and reporting, the 10% annualized usage number would be difficult for enforcement staff to verify. For example, if a biomass boiler co-fired with oil were to perform a stack test for CO, it would be required to meet the 100 ppm (@7% 0?) standard even if during the stack test it burned 99% oil, simply because it burned any amount of biomass. Since a precedent has been set in 40 CFR 60 with establishing emission limitations based on a weighted average between different fuel types, NHDES recommends that EPA provide this same mechanism in order to determine the applicable emission limitations for multi-fuel fired boilers.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Robert R. Scott
Commenter Affiliation: New Hampshire Department of Environmental Services, Air Resources Division
Document Control Number: EPA-HQ-OAR-2002-0058-2734.1
Comment Excerpt Number: 12

Comment: As an alternative, EPA could clarify in the regulation that if a device is operating under a dual fuel scenario, the device must comply with the lowest emission limit for each fuel burned. However, NHDES is concerned that by requiring multi-fuel fired units to comply with the lowest emission limit for each fuel type burned, this proposal would inadvertently push units into fuel switching situations that may result in boilers being required to meet more lenient standards. Therefore, NHDES also recommends that EPA encourage fuel switching not between solid and gaseous fuels but between "dirtier" and "cleaner" burning forms of the same fuel.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Arthur N. Marin
Commenter Affiliation: NESCAUM
Document Control Number: EPA-HQ-OAR-2002-0058-2893.1
Comment Excerpt Number: 19

Comment: EPA proposes allowing a facility to use up to 10% of an alternative fuel that a boiler is “designed” to burn without having to comply with the appropriate emission limit. NESCAUM finds this language problematic for several reasons. First, we suggest that EPA change the word “designed” to “permitted” to burn. While a unit may be designed to burn certain fuels, a state may have placed limitations on fuel use within a permit. Second, we have concerns with the 10% fuel use limit, as it creates significant enforcement issues. Without detailed requirements for tracking, recordkeeping, and reporting, the 10% limit will be difficult for enforcement staff to verify. Third, facilities’ use of the different fuels may vary from year to year, which leads to different emission limits from year to year. States would be unclear as to how to determine which emission limits would apply and when. Fourth, there are questions about what limits would apply when a boiler is simultaneously burning more than one fuel. NESCAUM recommends that EPA modify the rule to state that if a facility combusts more than one fuel type, it must meet the lowest applicable emission limit for the fuel types actually burned.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 154

Comment: Within the pulp and paper sector, there are a number of boilers (at least 30, based on the survey database developed by EPA) that co-fire coal in an amount greater than 10% heat input basis with at least 5% biomass. These combination boilers that simultaneously burn coal and biomass have different emission profiles than units that burn coal or units that burn biomass. As a result, we recommend EPA utilize a combination of the coal subcategory and biomass subcategory emission standards for these units.
As the rule is currently proposed, boiler units that burn more than 10% coal with biomass will be classified in the coal subcategory; however, they will not be able to meet the coal subcategory CO emission standard for organic HAPs due to the substantial amount of biomass that they burn. If these units cannot comply with the CO standard, these units may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards AF&PA notes that some boilers would not be able to switch fuels in the other direction (i.e., burn more biomass to become classified as a biomass boiler). Many boilers are designed to meet its rated steam load burning a designated fuel mix of coal and biomass. If the amount of biomass was increased significantly, the steam load would drop since biomass is a lower BTU fuel than coal resulting in a shortage of steam for the pulp and paper (or wood products) process.. This unintended consequence of replacing biomass with coal is contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.
We recommend the emission standards for coal/biomass combination boilers utilize a combination of the emission standards developed for the coal subcategory and for the biomass subcategory. Combination boilers burning more than 10% coal with biomass should be subject to the same emission standards for PM/metals, mercury, and HCl as the coal subcategory since the emissions of these pollutants are fuel dependent and will be driven primarily by burning coal. However, for all the following reasons, these combination boilers should be subject to the biomass subcategory emission limitations for organic HAP (CO and dioxins/furans).

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1

Comment Excerpt Number: 156

Comment: A combination boiler that co-fires biomass and coal will have a different CO emissions profile than a boiler that burns only coal. The CO emissions profile of these combination boilers will be like that of a boiler in the biomass subcategory for the following reasons:
* Wet biomass fuels (e.g., bark or hog fuel) have more variation in fuel quality and as such do not burn as evenly as coal. This variability results in higher CO emissions than coal combustion. This fact is recognized by EPA in the subcategorization of boilers burning these different fuels. The majority of biomass fuels burned by the pulp and paper industry are wet fuels, and the moisture content varies depending on the source of the fuel, the weather conditions (e.g., rainfall on outdoor storage piles), and the type of fuel (bark, sawdust, wood chips, etc.). Higher moisture fuels, as well as variations in moisture content, cause less even combustion and therefore, higher CO emissions.
* Many pulp and paper industry combination boilers burn wood residues from their wood yard operations, which do not run continuously. As such, the amount of wood residue burned varies throughout each day, as does the type of wood residue (bark, sawdust, undersized chips). Such variations in the fuel quality, size, and type cause less consistent combustion and therefore, higher CO emissions.
* EPA recognizes that wet fuels or varying moisture content of the fuel can result in incomplete combustion, and that the design of the unit influences organic HAP emissions. Specifically, the preamble to the proposed rule states:
"The design of the boiler or process heater, which is dependent in part on the type of fuel being burned, impacts the degree of combustion. Boilers and process heaters emit a number of different types of HAP emissions. Organic HAP are formed from incomplete combustion and are influenced by the design and operation of the unit." [35 FR 32017].

For establishing the organic HAP emission standards for combination boilers, we also considered and then dismissed a prorated approach. The prorated approach we considered involved the use of a sliding scale to prorate the biomass organic HAP emissions based on the quantity of biomass being co-fired over a 30-day averaging period. We did not favor a prorated approach for the following reasons:
* The amount of biomass material combusted would be accrued at the end of the averaging period. Once the amount of biomass combusted over the averaging period is determined, the source would calculate the prorated organic HAP limits for that averaging period. The limits to be complied with and the source's compliance status would be known "after the fact". Not knowing what limits a source needed to be complying with and not knowing compliance status until "after the fact" is untenable. Sources would essentially be "flying blind" as they would not know what their limits were until the end of the averaging period. We did not feel this was an acceptable approach.
* Many sources utilize inventory and purchase records for determining fuel throughput into the boiler units. On a longer term averaging basis, such as on an annual basis, this method of determining fuel throughput is reasonably accurate. This approach may not provide accurate estimates on a short term average basis and facilities may have to install more accurate metering or fuel throughput monitoring equipment at an additional cost.

* The prorated approach does increase the administrative burden of an already burdensome rule by requiring additional data collection, recordkeeping and reporting.
* Prorating may not be workable for combination boilers that co-fire liquid fuel and biomass since the organic HAP proposed limits for the liquid fuel sub-category are very stringent.
For the reasons given above, coal/biomass combination boilers will not be able to meet the proposed coal stoker, pulverized coal, and coal FBC limits of 50 ppm, 90 ppm, and 30 ppm CO, respectively. The proposed biomass stoker CO limit of 560 ppm is a more appropriate limit for stoker and pulverized coal combination boilers, and the proposed biomass FBC limit of 250 ppm CO is a more appropriate limit for combination FBC boilers. Adopting the biomass subcategory organic HAP emission limits (CO and dioxin) for coal/biomass combination boilers would establish more achievable limits for these boilers given the variability of the biomass fuels and boiler operating/design conditions.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Timothy Hunt

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 157

Comment: In order for EPA to adopt a combination of the coal subcategory and biomass subcategory emission limits for coal/biomass combination boilers, the proposed definitions of unit designed to burn biomass subcategory and unit designed to burn coal subcategory would have to be modified. We suggest that they be modified as follows:
Unit designed to burn biomass subcategory
i. For compliance with PM, HCl, and mercury standards, includes any boiler or process heater that burns at least 10 percent biomass, but less than 10 percent coal, on a heat input basis on an annual average, either alone or in combination with liquid fuels or gaseous fuels.
ii. For compliance with the CO and dioxin emission standards, includes
a. any boiler or process heater that burns at least 10 percent biomass, but less than 10 percent coal, on a heat input basis on an annual average, either alone or in combination with liquid fuels or gaseous fuels; and
b. any boiler or process heater that burns at least 5 percent biomass on a heat input basis on an annual average in combination with coal, liquid or gaseous fuels and that does not fall under the coal, gas1, gas2, or liquid fuel subcategories.
Unit designed to burn coal subcategory
i. For compliance with the PM, HCl, and mercury standards, includes any boiler or process heater that burns any coal alone or at least 10 percent coal on a heat input basis on an annual average in combination with biomass, liquid fuels, or gaseous fuels.
For compliance with the CO and dioxin standards, includes any boiler or process heater that burns any coal alone or at least 10 percent coal on a heat input basis on an annual average in combination with biomass, liquid fuels, or gaseous fuels, excluding those boilers or process heaters that burn at least 5 percent biomass on a heat input basis on an annual average.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: We agree in general with EPA's rationale that boilers should be subcategorized based on their fuel type and design; however, we do not agree that all boilers are designed to burn only one fuel type and that they will encounter operational problems if another fuel type is fired at more than 10 percent of heat input. Some boilers are specifically designed to burn a combination of fuels, and to burn them in varying quantities. According to one vendor who designs and builds boilers for various industries, 84% of the boilers are designed to fire combinations of fuels at any one time. In some cases, these boilers are not able to reach full load on any single fuel. From this information it would seem that EPA has incorrectly presumed that boilers are designed based on a primary fuel. Rather, boilers can be designed to fire a variety of fuels, encompassing various types of solid, liquid, and gaseous fuels. This practice provides the most flexibility to facilities and allows them to select fuel mix based on various factors that include cost, availability, season, weather, etc. The subcategories of boilers should not be based on the fuel a boiler or process heater is designed to burn, but rather the fuel the unit actually burns. With that said, EPA should clarify how and when units would move between subcategories in the rule based on the actual fuel mix fired and how and when compliance would be demonstrated for a different subcategory than the one the unit was under for the initial compliance demonstration.

Response: Please refer to the preamble for discussion of combination fuel units. See final rule and preamble for discussion of how units are assigned to subcategories and provisions available to switch subcategories.

Comment: EPA proposes allowing a facility to use up to 10% of an alternative fuel that a boiler is "designed" to burn without having to comply with appropriate emission limits. NHDES suggests that EPA change the word "designed" to "permitted" to burn. While a unit may be designed to burn certain fuels, a state may have placed limitations on the type of fuel used within a permit.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: The Maine DEP has several multi-fuel boilers that do not neatly fit into EPA's proposed categories of units "designed to burn" coal, biomass, or oil. These units are licensed to burn all three fuel types, and vary the amount of each fuel type burned based on availability, price, and demands on the boiler systems. Some of these units were originally designed many decades ago for one fuel type but have been subsequently modified to accommodate others. Does "designed to burn" mean licensed to burn, or how the unit was originally designed by the manufacturer?

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: We agree in general with EPA's rationale that boilers should be subcategorized based on their fuel type and design; however, we do not agree that all boilers are designed to burn only one fuel type and that they will encounter operational problems if another fuel type is fired at more than 10 percent of heat input. Some boilers are specifically designed to burn a combination of fuels, and to burn them in varying quantities. Pulp and paper industry coal/biomass combination boilers burn varying amounts of biomass and coal depending on factors such as fuel availability, wood fuel moisture, fuel cost, malfunctions in the fuel feed systems, and residuals management obligations. Also, the pulp and paper industry combination boilers that meet the proposed definition of a pulverized coal boiler burn pulverized coal like a traditional pulverized coal boiler and simultaneously burn biomass fuels on a stoker grate. Other combination boilers burn pulverized coal or petroleum coke along with biomass in a fluid bed combustor type of boiler. According to one vendor who designs and builds boilers for this and other industries, 84% of the boilers are designed to fire combinations of fuels at any one time. In some cases, these boilers are not able to reach full load on any single fuel. From this information it would seem that EPA has incorrectly presumed that boilers are designed based on a primary fuel. Rather, boilers can be designed to fire a variety of fuels, encompassing various types of solid, liquid, and gaseous fuels. This practice provides the most flexibility to facilities and allows them to select fuel mix based on various factors that include cost, availability, season, weather, etc. Combination boilers can sometimes burn 100% coal, 100% biomass, 100% liquid fuel, or 100% gaseous fuel, but typically burn mixtures of these fuels, based on various operational and economic factors. There is a difference between the worst case fuel a unit is permitted to burn or is capable of burning and the fuel mixture a unit will burn on an annual basis, so subcategory assignments should be based on actual fuel usage.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: EPA must adjust the proposed subcategories to properly accommodate the unique characteristics of combination boilers. Within certain industry sectors, boilers are commonly used that co-fire coal in an amount greater than 10% heat input basis with at least 10% biomass. These "combination boilers" that simultaneously burn coal and biomass have different emission profiles than units that burn coal or units that burn biomass. As a result, combination boilers do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA adjust the proposed subcategory for combination boilers so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and mercury) and the biomass subcategory for purposes of regulating the combustion-based HAP (i.e., CO (as a surrogate for organic HAPs) and dioxins/furans).

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: The FSI has one mill (in Hawaii) that burns both coal and bagasse in its three boilers. These boilers operate at times on bagasse only, coal only (mainly during the sugarcane processing off-season), and a combination of coal and bagasse. EPA is proposing to define boilers that burn at least 10 percent coal (on an annual heat input basis) as being in one of the coal subcategories (see pg. 32017). This is appropriate for fuel-based HAP, but not for organic HAP. Whenever a significant amount of bagasse is being burned in a boiler (>10 percent heat input), the resulting organic HAP emissions are significantly higher than when burning coal (or other fossil fuel) alone, making it impossible to meet organic HAP emission limits for coal-only burning. The higher the percentage of bagasse burned, the more influence on the overall organic HAP emissions. Therefore, FSI requests that any boiler burning bagasse (or biomass) at greater than 10 percent annual heat input basis be placed in the bagasse boiler (or biomass boiler) subcategory, and not in a fossil fuel subcategory.

Within certain industry sectors, boilers are commonly used that co-fire coal in an amount greater than 10 percent heat input basis with at least 10 percent biomass. These “combination boilers” that simultaneously burn coal and biomass have different emission profiles than units that burn coal or units that burn biomass. As a result, combination boilers do not fit into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA adjust the proposed subcategory for combination boilers so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and Hg) and the biomass subcategory for purposes of regulating the combustion-based HAP [i.e., CO (as a surrogate for organic HAPs) and dioxins/furans].

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 10

Comment: As the rule is currently proposed, boilers that burn more than 10 percent coal with biomass will be classified in the coal subcategory; however, most such boilers will not be able to meet the coal subcategory CO emission standard for organic HAPs due to the substantial amount of biomass that they burn. Biomass fuels are more variable than coal and typically contain significantly more moisture than coal. As a result, it is more difficult to control combustion conditions in combination boilers than in boilers combusting only coal, which means that CO emissions from combination boilers often will be unavoidably greater than from a comparable coal-fired boiler. This makes the coal subcategory an inappropriate choice for establishing standards for combustion-based HAP. Regulating combustion-based HAP from combination boilers under the biomass subcategory makes more sense because combination boilers will perform more like biomass-fired boilers with regard to the combustion related HAPs.

On the other hand, biomass typically has lower levels of metals, halogens, and Hg than coal. As a result, regulating the fuel-related HAPs from combination boilers under the biomass subcategory would be inappropriate because the amount of co-fired coal would in many cases prevent combination boilers from meeting the standards for fuel-based HAPs. For this reason, it makes more sense to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 21

Comment: For multifuel boilers under the proposed Rule the unit can only be in one classification, even though the characteristics of two subcategories exist and both predominate. In the case of using more than 10% coal, the coal classification is primary. However, for CO, using the coal conditional maximum for what is essentially a large percent biomass boiler is likely an impossible standard to meet. The Rule must be modified to address multifuel boilers to bifurcate the emission limits, with fuel based emissions (PM, HC1, Hg) based on the coal classification and combustion based emissions (CO, dioxin/furan) based on the biomass classification. Alternatively, additional subcategories to address various multi-fuel boiler configurations must be added to the Rule.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 62

Comment: The special case of units that fire both gas and liquid in the same burners needs to be addressed.
Many boilers and process heaters at refineries that do not have natural gas access are designed to be able to burn gas and liquid in any combination, as are some boilers and process heaters in other refineries. A picture of a standard John Zink combination design appears below, with an oil gun in the center, surrounded by gas burners.

[See submittal for image of a typical combination gas and oil burner.]

EPA, in establishing its gas and liquid subcategories, does not appear to have considered this type of combination operation. The Agency states on page 32017 of the preamble:

“These subcategories are based on the primary fuel that the boiler or process heater is designed to burn. We are aware that some boilers burn a combination of fuel types or burn a different fuel type as a backup fuel if the primary fuel supply is curtailed. However, boilers are designed based on the primary fuel type (and perhaps to burn a backup fuel) and can encounter operational problems if another fuel type that was not considered in its design is fired at more than 10 percent of the heat input to the boiler.”

This combination burner design is specifically designed so that it can fire up to 100% oil or gas or fire both in varying quantities on the same burner. They are a completely different design than EPA contemplated in setting its standards and cannot be fairly included in the same subcategory with other units.

There are several aspects of the co-firing design that are significant from a combustion perspective. First, when a burner is operating on both gas and oil, the gas flame can rob the oil gun of oxygen and result in higher CO emissions. Second, the need to fire up to 100% of the fuel in a heater or boiler as either oil or gas means that the firebox design cannot be optimized to maximize combustion efficiency. As a general rule, a firebox is designed to be about 2/3rds of the flame height of fuel being fired. However, this is not possible in a co-fired unit, because of the different heights and characteristics of oil and gas flames:

[See submittal for image of photographs showing differing flame characteristics of liquid and gas flames in a unit with combined oil/gas burners.]

The result is that the process heater/boiler firebox configurations for such co-fired units are a compromise which does not maximize combustion efficiency or NOx emissions because it cannot be designed to do so.

For these reasons, boilers and process heaters with combination burners should be in their own subcategory.

Recommendation: Establish a subcategory for gas/liquid boilers and process heaters which use combination.

Recommendation: Apply the tune-up work practice requirements to gas’liquid boilers and process heaters which use combination burners.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: Table 1 and 2 Emissions Limits
Combination Fuels.
Under the Proposed Rule, boiler units that burn more than 10 percent coal with biomass will be classified in the coal subcategory. 75 FR 32065. The 10 percent threshold established by EPA is arbitrary and EPA has failed to justify it as an appropriate threshold for defining a primary fuel. EPA then included emission data from such boilers along with 100 percent coal-fired boilers to establish standards for new and existing sources. This is inherently unfair to both biomass and coal fired boilers. Coal-fired boilers will inherently have higher emissions of HCl and mercury whereas biomass boilers will inherently have higher CO emissions.

This threshold is especially problematic for units that burn biomass with coal. If these predominantly biomass burning units exceed the arbitrary 10 percent threshold, they will be required to comply with the coal subcategory emission standard for CO. Such units are unable to meet the CO emission standard for coal. CIBO recommends that EPA amend the Proposed Rule to include an additional subcategory for combination boilers that burn both coal and biomass. EPA should reverse its methodology and only use data from boilers burning at least 90 percent coal to set standards for the coal subcategories and to use data from boilers burning less than 10 percent coal to set standards for the biomass subcategories. For combination boilers, EPA should allow compliance to be determined using weighted averages such as in NSPS Db where EPA used this methodology for sulfur dioxide and NOx. We do not see any issues related to enforceability of such weighted average standards that cannot be overcome with today's information technology. Another option is for EPA to apply the CO and dioxins/furans emission limits for the biomass subcategory to units in this new subcategory.

Such an approach is justified for a variety of reasons. First, if units that co-fire biomass and coal cannot comply with the CO standard it is likely they will switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. Discouraging the use renewable biomass fuel is contrary to current U.S. energy policy.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Cynthia L. Karlic
Commenter Affiliation: NRG Energy, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2822.1
Comment Excerpt Number: 1

Comment: NRG owns and operates several boilers which may be considered gas-fired ICI boilers under the proposed ICI MACT rule. Some of the boilers have dual fuel-firing capability utilizing natural gas and liquid fuel. These dual fuel-fired boilers could fall under the "Unit designed to burn gas 1 (NG/RG) subcategory ("Gas ICI Boiler"). However, the ICI MACT rule states that the "Unit designed to burn gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average."

The use of the 90% heat input criteria on an annual basis to determine if an ICI boiler is a Gas ICI Boiler may be problematic for the dual fuel-fired boilers because in any individual year the boiler may have a gas-fired heat input less than the 90% criteria. This would cause the boiler to be in the Gas ICI Boiler subcategory for a year, in the "Unit designed to burn oil" subcategory ("Oil ICI Boiler") in a subsequent year, and then back to the Gas ICI Boiler in a third year. Changing categories on an annual basis based on a single year's heat input is impractical and may lead to compliance issues for both the regulated source and regulators.

Commenter Affiliation: Decorative Panels International, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2599.1
Comment Excerpt Number: 2

Comment: DPI's Alpena plant requires significant energy resources from three industrial boilers to produce the steam and power requirements for its hardboard process. All three exhaust through a common stack. Each of the boilers is permitted to burn multiple fuels, although two of the boilers are primarily coal fired and the third is primarily wood fired. Alternative fuels include natural gas, used oils and biomass materials such as wood dust, bark, and wastewater treatment sludge. The air emissions profile of multi-fueled boilers varies with fuel mix and moisture contents, making is difficult to establish a "typical" emissions profile. The fact that these boilers must often adapt quickly to varying process steam demand and experience frequent load swings also makes characterizing typical emissions difficult.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Sean M. O'Keefe
Commenter Affiliation: Alexander and Baldwin, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 3

Comment: Biomass-fired boilers should not be required to meet standards that are based on emissions from boilers firing coal; EPA needs to modify its approach to regulation of "combination boilers" burning multiple fuels.
The proposed rule would place in the "unit designed to burn coal subcategory" any boiler that burns coal alone or that burns at least ten percent coal on an annual heat input basis in combination with biomass, liquid fuels, or gaseous fuels. Any boiler in this subcategory would be required to meet standards that are based on emissions from the best-performing sources in

the subcategory, as measured during coal firing. These emissions limits would have to be met at all times when the boiler is operating, regardless of what fuel is being fired. A&B believes that this approach is fundamentally flawed because it establishes emissions limits for boilers firing biomass fuels that are based on the emissions performance of boilers firing coal, a fuel with a vastly different emissions profile.

The Puunene Mill boilers fire primarily renewable biomass fuel, sugarcane bagasse produced in the mill, which typically comprises 60 to 70 percent of the annual heat input to the three boilers. [Since 2001, when the plantation closed its sugar mill at Paia and converted to single mill operation, bagasse has accounted for just over 71 percent of the annual average heat input to the Puunene Mill boilers. Historically, the boilers have been categorized in their permits to operate and/or under state air pollution control regulations as "biomass boilers" with a minimum of 50 percent of the annual heat input to each boiler coming from biomass fuel.] In order to meet its power generation commitments during maintenance periods when bagasse is not being produced by the mill, and to allow stabilization of the boilers during fluctuations in biomass fuel quality or when the bagasse supply to the boilers is temporarily interrupted, the boilers also fire limited amounts of coal, both alone and in combination with biomass. Thus, despite the fact that the Puunene Mill boilers were constructed at an operating sugar mill for the purpose of generating steam by burning bagasse produced by the mill, under the proposed rule these boilers would be categorized as "stokers designed to burn coal" and would be required to meet the corresponding emissions limits in the proposed rule, including a carbon monoxide (CO) emission limit of 50 ppm by volume (corrected to three percent oxygen), at all times, including when firing biomass fuels.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Sean M. O'Keefe
Commenter Affiliation: Alexander and Baldwin, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 4

Comment: Sugarcane bagasse typically contains approximately 50 percent moisture, as fired, though moisture can range as high as 55 to 60 percent depending upon mill operations and harvesting conditions. Bagasse is produced as the sugarcane is ground in the mill and is routed directly from the mill to the boilers to be combusted. Thus, any fluctuations in mill operations or in the quality of cane being milled are directly and immediately transmitted to the boilers in the form of fluctuations in fuel quality, including fuel moisture. By comparison, coal burned at HC&S has a moisture content of ten percent or less, with very little variation. The high moisture content and variability of the bagasse fuel, combined with design characteristics of the boilers developed to burn this fuel, result in CO emissions from burning bagasse (and many other biomass fuels) that are typically one to two orders of magnitude higher than those generated by burning coal in the same boilers. [See, for example, the discussion of bagasse boiler CO emissions in Boiler MACT Report - Bagasse Boilers Should be Regulated in a Separate Subcategory under the Boiler MACT Rules Because they are a Unique Class of Boilers (Golder

Associates; July 2010) and CO emissions data for bagasse fired boilers included in MACT Floor Analysis for Bagasse Boiler Subcategory (Golder Associates; August 2010), both of which have been submitted to the docket for this rule, and emissions data from coal firing in Puunene Boiler 3 (identified as a "best performing unit" in the coal stoker subcategory), submitted in response to the EPA Boiler MACT Combustion Survey of September 2008.] A&B therefore believes that it is unreasonable to expect that CO emissions of 50 ppm can be reliably achieved by either suspension burners, stoker boilers, or fuel cells firing biomass fuel, particularly a biomass fuel such as bagasse which has such a high, and highly variable, moisture content. EPA has as much as acknowledged that this level of emissions is not achievable by even the best performing boilers of these types when firing biomass, since it has proposed a CO emissions limit for new suspension burners designed to burn biomass as high as 1,010 ppm. A&B is unaware of any available control technology with the capability of reducing emissions from its biomass-fired boilers from their current levels to the level proposed for the coal stoker subcategory. Yet both new and existing combination boilers would be required to meet this limit when firing biomass or would be unable to continue operating.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Thomas Bakk
Commenter Affiliation: State of Minnesota Senate
Document Control Number: EPA-HQ-OAR-2002-0058-2950
Comment Excerpt Number: 4

Comment: Minnesota and national energy policy strongly encourages the use of biomass to provide energy and heat for industrial production. The forest products industry is a leader in energy generation from biomass. Unfortunately, the proposed rule will penalize boilers that co-fire coal and biomass. Because these "combination" boilers have different emission profiles from boilers that burn only coal or biomass, they don’t fit into either the coal-fired subcategory or the biomass subcategory. We believe that EPA should include combination boilers burning more than 10% coal in the coal subcategory for the purpose of setting emission standards for particulate/metals, mercury and acid gases and the biomass subcategory for emissions of carbon monoxide and dioxins/furans.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Sean M. O'Keefe
Commenter Affiliation: Alexander and Baldwin, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3196
Comment Excerpt Number: 5

Comment: On the basis of CO emissions alone, there is clearly an urgent need to revise the proposed boiler subcategories so that emissions limits for combination boilers firing biomass fuels will be correctly established based on the best-performing similar units rather than on the best-performing coal-fired units. [It is A&B's understanding that of the units forming the basis for the MACT Floor for CO emissions from coal stoker boilers, only one — Puunene Boiler 3 — fires any biomass fuel.] One option for addressing this issue would be to simply revise the proposed definitions of "unit designed to burn biomass subcategory" and "unit designed to burn coal subcategory" so that units which burn significant quantities of biomass, and certainly units which burn primarily (i.e., more than 50 percent) biomass, would be placed in the biomass rather than in the coal subcategory. While this approach is not without its limitations — it would not necessarily address concerns regarding emissions of fuel-based HAPs (see further discussion below) - it would at least address the inappropriately low, and likely unachievable, proposed limits on CO emissions from combination boilers firing biomass fuels.

An alternative approach to addressing combination boilers would be to recognize that they do not fit cleanly into either the coal-fired or biomass-fired boiler subcategory. That is, while it makes sense to regulate combination boilers as biomass-fired boilers with regard to combustion-based HAPs (CO and dioxins/furans), when firing coal they may be unable to meet limits on fuel-related HAPs under the biomass subcategory due to the lower levels of metals, halogens, and mercury typically found in biomass fuels. Thus, it may make more sense to subject combination boilers to the same emission standards for PM/metals, mercury, and acid gases as the coal subcategory while applying the biomass subcategory emissions limitations for CO and dioxins/furans. A&B strongly endorses this approach. However, in the event that this broader approach proves to be infeasible we believe it is critically important for EPA to ensure that appropriate CO emissions standards are applied to combination boilers which fire significant quantities of biomass by assigning these boilers to the biomass subcategory.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Leslie Sue Ritts
Commenter Affiliation: National Environmental Development Association's Clean Air Project NEDA/CAP
Document Control Number: EPA-HQ-OAR-2002-0058-2794.1
Comment Excerpt Number: 6

Comment: Because EPA has overlooked or ignored the combustion chemistry interactions between some pollutants, the proposed standards are arbitrary and unreasonable.

Because EPA analyzed testing performed by industry across a large sample of industrial boilers but segregated the results by pollutant in establishing the MACT floors, it appears that very few sources (including those identified as best performers for certain HAPs) can meet the proposed standards. EPA appears to have overlooked the combustion chemistry interactions between some pollutants, such as PM and CO with mercury and hydrogen chloride. In addition, EPA has seemingly ignored the fact that most multi-fuel boilers burn a variety of fuels over the year depending on costs, availability, transportation costs, etc., because the proposed MACT standards are based on control equipment that can be optimized for one HAP or fuel, but the simultaneous effect for other HAPs, other fuels or on other control equipment performance is either unknown or incompatible. We submit that this topic should be evaluated for each proposed MACT emission limit when the set of boilers at issue use multiple fuels or that EPA must explain why such criteria are not inherent in the statutory term “achievable.”

Response: See the preamble for response to the pollutant-by-pollutant approach and achievability of standards as well as response to how the subcategories and thresholds were adjusted in the final rule to better accommodate combination fuel boilers.

Comment: Multi-fuel boilers should be addressed as appropriate subcategories as needed.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: David Bonistall
Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 9

Comment: NewPage has a number of boilers that are designed to simultaneous co-fire coal in an amount greater than 10% on a heat input basis and with greater than 10% biomass. These units are designed with coal and biomass as primary fuels. According to the boiler design descriptions and performance information, these units can simultaneously burn significant amounts of coal and/or biomass where up to 70% of the heat input could be supplied by either of these primary fuels.

These "combination boilers" that co-fire coal and biomass have different emission profiles than units that burn coal or units that burn biomass. As a result, combination boilers do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA adjust the proposed subcategories so combination boilers belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and mercury) and the biomass subcategory for purposes of regulating the combustion-based HAP (i.e., CO (as a surrogate for organic HAPs) and dioxins/furans). Although an alternate approach would be for EPA to create a separate combination boiler sub-category. NewPage does not support this approach as the amount of data in the database to determine the combination boiler subcategory floors would be much more limited than our proposed approach.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 9

Comment: In many industries there is a push to include biomass in the fuel mix of boilers that rely primarily on fossil fuel. However, for example, EPA proposes to define a boiler that burns at least 10% coal as subject to the MACT for coal-fired boilers. The proposal to define and regulate any boiler using less than 10% coal and more than 10% biomass as a pure biomass boiler is similar. Both these proposed definitions have the potential to create a significant disincentive to the development and use of mixed fuel boilers and operation schemes, and could serve to limit the future development of biomass fuels.

USW therefore urges EPA to consider a separate subcategory for true mixed-fuel boilers that will be sufficient to protect the public health, but will allow in particular the innovative development and use of biofuels as a viable economic option and clean energy job generator.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: David Bonistall
Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 10

Comment: As the rule is currently proposed, boilers that burn more than 10% coal with biomass will be classified in the coal subcategory; however, these boilers will not be able to meet the coal subcategory carbon monoxide (CO) emission standard for organic HAPs due to the substantial amount of biomass that they burn. Biomass fuels are more variable than coal and typically contain significantly more moisture than coal. As a result, it is more difficult to control combustion conditions in combination boilers than in boilers combusting only coal, which means that CO emissions from combination boilers often will be unavoidably greater than from a comparable coal-fired boiler. This makes the coal subcategory an inappropriate choice for establishing standards for combustion-based HAP. Regulating combustion-based HAPs, in particular CO, from combination boilers under the biomass subcategory makes more sense because combination boilers will perform more like biomass-fired boilers with regard to the combustion related HAPs.

On the other hand, biomass typically has lower levels of metals, halogens, and mercury than coal. As a result, regulating the fuel-related HAPs from combination boilers under the biomass subcategory would be inappropriate because the amount of co-fired coal would in many cases prevent combination boilers from meeting the standards for fuel-based HAPs. For this reason, it makes more sense to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Comment Excerpt Number: 19

Comment: MidAmerican Requests Clarification on what limits apply to Dual-Fueled Units. In this proposed rule, the EPA suggests that new or existing boilers or process heaters which burn at least 10 percent coal, biomass, liquid fuel, or gaseous fuel would fall into the corresponding fuel subcategory. However, the EPA fails to account for dual fueled units that have the capability to utilize more than one fuel type over the 10 percent threshold level. For example, if a boiler has the capability to run on natural gas, coal, and/or biomass at any point in excess of 10%, with the fuel choice dictated by economics and availability, what fuel category would be applied under such a multi-fuel scenario? MidAmerican requests clarification from EPA regarding this issue.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 39

Comment: EPA's method of assigning units to a particular fuel subcategory may be inappropriate for units that co-fire multiple fuel types. EPA attempted to map specific fuels to the generic list of fuel types (i.e. "sander dust" - "biomass", "pet-coke" - "coal"). For many fuels, this mapping strategy is straightforward. However, for units that co-fire multiple fuel types (i.e. "coal/biomass", "coal/natural gas") where a breakdown of the heat input from each fuel type was not provided during the emissions test, EPA appears to have assigned these units to the fuel type containing the highest overall HAPs concentration. For example, "coal/natural gas" was assigned to the "coal' subcategory. Since the relative heat input contribution during the test is unknown, there is no way to quantify the bias this might create in the emissions data pool for each fuel type. Unfortunately, this appears to be common for many of the reported emissions tests, particularly for biomass-fired units.

RMB notes that correctly assigning units based on fuel type may be an impossible task given that the necessary data was probably never provided. Sources may not have had the capability of measuring individual fuel flows and/or EPA's spreadsheet templates may not have had the specific fuel type listed for one or more of the fuels combusted during the test.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company

Comment Excerpt Number: 48

Comment: A significant number of units in the coal-, biomass-, and liquid subcategories (HCl, PM, Hg, CO, and D/F-TEQ) were co-firing gas during the ICR emissions test. Average heat input from gas firing (either 'Gas 1' or 'Gas 2') ranged from 2% - 90% of total heat input although in most cases co-firing was less than 10%. Gas co-firing introduces a bias in the emissions for non-gas subcategories because emissions are averaged with a lower HAP-containing fuel. This bias can be significant depending on the gas firing rate and relative difference in pollutant concentration. For instance, the bias in PM emissions due to 15% natural gas co-firing for a biomass-fired unit that has typically has PM emissions of 0.02 lb/mmBtu during biomass (only) combustion is approximately 15%. RMB recommends that EPA either exclude all test runs where a unit was co-firing gas or adjust the data accordingly to remove the gas-firing bias. This would result in an emissions pool for each subcategory where the emissions are based on the equivalent of 100% combustion of the fuel type for that subcategory. A complete list of test runs containing gas co-firing can be found in Attachment C.

Document Control Number: EPA-HQ-OAR-2002-0058-2863.1
Comment Excerpt Number: 29

Comment: 5.EPA Incorrectly Assumes that a Heater or Boiler is Designed Around a Single Fuel

Because island/remote refining or loading facilities do not have access to natural gas, they must supplement their fuel gas with oil. The amount of gas available can vary substantially, as noted above. For example, during a turnaround of an FCC unit that makes substantial amounts of fuel gas, heaters and boilers that typically burn almost all fuel gas must be able to burn almost entirely fuel oil to remain in operation. As a consequence, heaters and boilers on island facilities like HOVENSA must be designed to be able to burn far more than 10% gas or oil. These units are designed to be dual fuel units, able to provide the heat inputs needed on both fuels. (see submittal picture of a standard John Zink combination burner design, with an oil gun in the center surrounded by gas burners.)

EPA, in establishing its subcategories, did so on the incorrect assumption that a unit is designed for one type or fuel or another, and set a maximum 10% threshold for the alternate fuel:

Commenter Affiliation: Marquette Board of Light and Power
Document Control Number: EPA-HQ-OAR-2002-0058-3175
Comment Excerpt Number: 1

Comment: The Marquette Board of Light and Power submitted a plan to the State of Michigan to achieve the targets by fuel switching to biomass in the coal fired stoker boiler. The low ash content of the wood-based biomass material may require that a blend with coal will be necessary. While our intent is to minimize the amount of coal used in the fuel blend by maximizing the amount of biomass combusted, it may require that more than 10% of the blend be made up of coal. This means that the carbon monoxide emission limit would be 50 ppm when combusting the biomass/coal blend if the 2010 boiler MACT goes into effect. Based on our experience with trying to combust biomass, the new limit will force us to abandon this project and continue burning coal as the only fuel in this unit.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Richard Rosvold
Commenter Affiliation: Xcel Energy Services, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2955.1
Comment Excerpt Number: 2

Comment: Xcel Energy owns and operates boilers that burn coal and biomass in the same boiler, but not concurrently. The data acquisition and handling system component of the continuous emissions monitoring system (GEMS) on these units tracks the F-factor associated with the fuel being combusted on a minute basis, making it easy to distinguish when a particular fuel is being combusted. For these units, it makes sense for the carbon monoxide (CO) limits to be based on the fuel being burned at the time, not by arbitrarily placing these units in one category or the other. In fact, it would be fairly straightforward for these units to comply with different CO limits based on the fuel being burned at the time. Having over thirty years of experience burning these fuels in these boilers, we are certain that the CO limit prescribed for coal-burning units cannot be achieved while burning biomass. We therefore request the EPA allow boilers burning a variety of fuels to comply with the emission limits for the specific fuel being burned if the emissions from that boiler are being monitored by CEMs.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Tim Hagley
Commenter Affiliation: Minnesota Power
Document Control Number: EPA-HQ-OAR-2002-0058-2829.1
Comment Excerpt Number: 2

Comment: The Proposed Rule Will Discourage or Prevent Co-Firing of Biomass by Applying Coal-Fired Unit Based CO Emission Limits that are Unachievable while Cofiring with Biomass. Minnesota Power is aggressively expanding the use of renewable, clean energy resources through new wind projects, and maximizing our biomass and hydro resources, consistent with national energy and climate policy and Minnesota renewable energy standards. We have two facilities that co-fire biomass with coal to produce energy, and we continually look for ways to maximize our use of biomass. One facility, REC, has two solid fuel boilers co-firing biomass that meet the definition of industrial boilers, and would be impacted by this rule.

The rule requires those sources that co-fire biomass with coal, to apply the coal fired emission limits if coal comprises more than 10 percent of the fuel mix. On average, REC burns a blend of 70% biomass (primarily wood chips) and 30% coal in the stoker fired boilers, however on an hourly basis, the blend may vary. The proposed coal-based emission limit for CO is roughly an order of magnitude more stringent than the biomass limit for a stoker-fired boiler (50 ppm vs. 560 ppm), and is not achievable with our existing boilers while co-firing with biomass. A preliminary analysis makes it clear that, even with expensive modifications to the boilers, the coal-based emission limit for CO may still be unattainable. Biomass fuels are more variable in size and moisture content than coal, making it more difficult to control combustion conditions, contributing to higher CO emissions, which explains the higher CO emission limit for stoker-fired biomass boilers.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: Adjusting the proposed subcategories to correctly accommodate the unique characteristics of combination boilers, which simultaneously burn coal and biomass. These combination boilers have different emission profiles and do not fit into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Jim Weeks
Commenter Affiliation: Michigan Municipal Electric Association
Document Control Number: EPA-HQ-OAR-2002-0058-2795.1
Comment Excerpt Number: 5

Comment: For Marquette Shiras Unit 2 and other existing electricity boilers that are striving to move toward a cleaner, more diversified fuel supply using biomass fuels, EPA should amend the subcategory for combination coal-biomass boilers to promote the use of renewable biomass fuel, and to address the severe difficulties that certain combination units will have meeting the proposed technology-based standards.

Marquette is planning on meeting the state renewable portfolio standards by blending a mixture of wood biomass (Reriewfuel) with bituminous coal (the exact ratio has yet to be determined). However, in a unit such as IvIarquettels Shims Unit 2 that may be burning up to a 50/50 blend of biomass and coal, it will be extremely difficult if not impossible to meet the coal sub-category's CO emission standard for organic HAPs. Yet, a blended/combination boiler cannot be simply subject to the proposed biomass subcategory limitations either, because a blended combustion may result in higher PM, metals, mercury and acid gases.

EPA's rule, as proposed, would likely require Marquette to reduce biomass fuel stocks drastically and return to primarily coal combustion at Unit 2. This is a perverse policy incentive given the greenhouse gas reductions possible from biomass use. in addition, Marquette and the State of Michigan are counting on projects like the Shiras Renewafuel project to catalyze and support the biomass industry in critical areas of the state where biomass supply is not yet certain. Likewise, Marquette is counting on the Shiras biomass generation to allow the system to meet the Renewable Energy Standard (portfolio standard) created by Michigan Act 295, the "Clean, Renewable and Efficient Energy Act of 2008." Again, under EPA's proposed categorization of a unit such as Shiras 2 as a coal sub-category unit that must meet CO limits that are likely unachievable for combination units with significant biomass capacity, Marquette may have to abandon or significantly reduce this renewable resource.

A blended-fuel, combination boiler needs a "blended" set of emissions limitations to reflect the technical and policy factors at combination boilers. For these reasons, MMEA and Marquette ask EPA to review the way that biomass-coal combination boilers will be regulated under the MACT. Boilers burning more than 10 percent coal with biomass should be subject to the same emission standards for PM/metals, mercury and acid gases as the coal snbcategory, but also be subject to the biomass sub-category limitations for CO and dioxins/rums.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 6

Comment: Within certain industry sectors, boilers are commonly used that co-fire coal in an amount greater than 10 percent heat input basis with at least 10 percent biomass. These "combination boilers" that simultaneously burn coal and biomass have different emission profiles than units that burn only coal or units that burn only biomass. As a result, combination boilers do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, EPA should adjust the proposed subcategory for combination boilers so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP and the biomass subcategory for purposes of regulating the combustion-based HAP.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Tom Midyett
Commenter Affiliation: Tennessee Paper Council
Document Control Number: EPA-HQ-OAR-2002-0058-2691.1
Comment Excerpt Number: 7

Comment: As the rule is currently proposed, boilers that burn more than 10 percent coal with biomass will be classified in the coal subcategory; however, most such boilers will not be able to meet the coal subcategory CO emission standard for organic HAPs due to the substantial amount of biomass that they burn. Biomass fuels are more variable than coal and typically contain significantly more moisture than coal. As a result, it is more difficult to control combustion conditions in combination boilers than in boilers combusting only coal, which means that CO emissions from combination boilers often will be unavoidably greater than from a comparable coal-fired boiler. This makes the coal subcategory an inappropriate choice for establishing standards for combustion-based HAP. Regulating combustion-based HAP from combination boilers under the biomass subcategory is more appropriate because combination boilers will perform more like biomass-fired boilers with regard to the combustion related HAPs.

On the other hand, biomass typically has lower levels of metals, halogens, and mercury than coal. As a result, regulating the fuel-related HAPs from combination boilers under the biomass subcategory would be inappropriate because the amount of co-fired coal would in many cases prevent combination boilers from meeting the standards for fuel-based HAPs. For this reason, it is more appropriate to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Notably, if owners or operators of combination boilers anticipate difficulty complying with the proposed CO standard, they may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. This unintended consequence is in direct contravention of national and local environmental and climate policy encouraging the use of renewable biomass fuels.

Document Control Number: EPA-HQ-OAR-2002-0058-2913.1
Comment Excerpt Number: 7

Comment: The Rule proposes five boiler subcategories based on the type of fuel cornbusted, namely, coal, biomass. liquid fuel, natural/refinery gas and other gas; coal and biomass subcategories are further subdivided by boiler types. Of PCA's thirteen power boilers, the rule classifies six as coal (stoker), two as biomass (stoker), two as liquid fuel, two as "other gas" and one as natural gas.

EPA has elected to include in the coal subcategory all units that use coal at a rate greater than 10 percent of the heat input. Three of our company's "coal" boilers combust coal, along with a host of other fuels such as woody biomass (bark, sawdust, fiber rejects), tire-derived fuel, old-corrugated container rejects and wastewater treatment plant residuals. This practice serves three rational purposes, a) it takes advantage of those materials that are produced on-site and have fuel value, b) it reduces the amount of material that might otherwise go to landfills, and c) it offsets the use of purchased fossil fuels. By failing to recognize the wide diversity of fuel inputs, the variation in availability of these fuels and the inherent variation in fuel quality (i.e., BTU and moisture content) and related impact on source emissions, EPA effectively penalizes facilities that maximize the use of these fuel streams by applying a "one size fits all" approach to emission limits in the context of a very restricted number of subcategories. It will have the unintended consequence of forcing some facilities to burn more coal in efforts to meet compliance with this rule.

We recommend that the Agency rework the source subcategories to include boilers that combust a combination of solidfuels and establish emission limits reflective of the variation in fuels andfuel quality.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Kirby D. Juntila

Document Control Number: EPA-HQ-OAR-2002-0058-3175
Comment Excerpt Number: 8

Comment: The EPA needs to consider a co-firing subcategory for coal and biomass. A boiler burning a 50% coal/50% biomass blend will not meet the 50 ppm CO limit. Essentially, this rule provides no incentive to burn biomass unless a boiler can operate on biomass alone. Burning biomass alone may not be feasible in existing coal-fired stoker units due to the low ash content of the biomass and the inability to form an ash bed on the traveling grates. The EPA needs to consider adding a category that offers an incentive to offset the combustion of coal with biomass meeting limits somewhere between the stokers designed to burn coal and the stokers designed to burn biomass. This needs to be taken into consideration so that the EPA does not implement a rule that would conflict with the Renewable Portfolio Standards being adopted by many proactive states in an effort to move away from electricity generated from the combustion of coal.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: Mark W. Kowlzan
Commenter Affiliation: Packaging Corp. of America
Document Control Number: EPA-HQ-OAR-2002-0058-2913.1
Comment Excerpt Number: 8

Comment: Within PCA three of our thirteen boilers co-fire coal in an amount greater than 10% heat input basis along with at least 10% biomass. These "combination boilers" have different emission profiles than units that burn exclusively coal or exclusively biomass. In all cases, coal constitutes a minority fuel in these combination boilers. The units perform more like coal boilers with respect to fuel-based emissions (e.g .. PM, HCI and Hg) and perform more like biomass boilers with respect to combustion-based emissions (e.g., CO and DIF).

It is important that EPA recognize that by placing combination boilers burning substantial amounts of biomass in the coal subcategory the boilers will be unable to meet the CO emission standard based on coal firing due to the variable moisture content of biomass and its impact on combustion conditions. Similarly, biomass typically has lower levels of metals, halogens, and Hg than coal. Placing combination boilers in the biomass subcategory is inappropriate due (0 the influence that coal exerts on the fuel quality / emissions characteristics due to coal's higher levels of metals, halogens and Hg, Therefore, it makes more sense to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Given these realities, EPA should revise the way combination boilers are regulated under the proposed Boiler MACT. Specifically, combination boiler emission standards should be bifurcated. Combination boilers burning more than 10% coal with biomass should be subject to the coal subcategory PM/metals, Hg, and acid standards and should be subject to the biomass subcategory standards (if any) for co and dioxinsljurans.

Response: Please refer to the preamble for discussion of combination fuel units.

Commenter Name: David M. Kiser

Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 9

Comment: The data submitted shows that coal fired boilers that co-fire other fuels such as biomass will have a CO profile more akin to a biomass unit. Therefore, coal/biomass boilers will not be able to meet the proposed CO limits of 50 ppm (stokers designed to burn coal). The proposed limit of 560 ppm (stokers designed to burn biomass) is a more appropriate limit as demonstrated by the data in Attachment 4. Therefore any boiler firing more than 10% biomass should be subject to the appropriate biomass limit for CO regardless of what other fuels it fires.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 9

Comment: GPI — Macon Mill operates a multi-fuel boiler that primarily combusts biomass (as defined by the proposed rule) and is also capable of combusting coal, fuel oil, and natural gas, historically at annual heat input capacities less than 10%. However, the boiler does have the potential to combust coal in excess of 10% heat input capacity on a short-term basis and, theoretically, even on an annual capacity basis. [From an operations perspective, there is a higher incentive to combust biomass than coal given fuel costs.] For example, in reviewing hourly fuel usage data on this unit, GPI — Macon Mill has operated the unit in the past two years at greater than 10% coal (heat input basis) for approximately 8% of the total hours of operation, with isolated hourly spikes around 90% of the heat input at that time. Accordingly, GPI — Macon Mill has the following concerns that arise based on the subcategory definition as proposed:

1. Is EPA intending that enforceable permit conditions be established limiting a multi-fuel boiler as described to less than 10% annual heat input capacity from coal?

2. If EPA is intending to establish enforceable conditions, would this limit be tracked on a calendar-year basis or 12-month rolling total basis? Any time-frame shorter than this would impede on flexibility needs for operation of a multi-fuel boiler (i.e., addressing fuel availability, fuel quality).

3. If a unit that historically operated at less than 10% annual heat input capacity from coal were to exceed the 10% basis in one year, would the classification of the unit change from designed to combust biomass to designed to combust coal? If yes, how would this be handled from a permitting and compliance perspective?
4. In general, GPI - Macon Mill feels that EPA needs to more specifically address the "enforceability" of the "designed to burn" classification and more clearly consider the implications of the multi-fuel boiler operation on testing considerations.

Comment: Unit categorization clarifications. These categories do not fit actual operating units. Although a particular unit may have a primary fuel associated with it, they may also be able to operate without restrictions on the secondary fuel. Choice of fuel may simply be an economic decision. The rule should allow these choices. For example, what category is a unit that burns 50 percent coal and 50 percent liquid fuel or a unit that burns 50 percent liquid fuel and 50 percent natural gas? The proposal lists the Gas 1 subcategory as burning at least 90 percent natural gas. What happens if during one year a unit burns 90 percent natural gas and 10 percent liquid fuels, but the next year burns 90 percent liquid fuels and 10 percent natural gas? Do the applicable requirements, including performance testing, etc., change from year to year? Are the performance tests required only for the primary fuel? What happens if in the middle of the year a unit goes from having burned only one type of fuel to only another type the rest of the year — is this action precluded until an "annual" performance test can be conducted on the second fuel? These questions raised by actual use of operating units should be addressed.

Response: Please refer to the preamble for discussion of combination fuel units. See final rule and preamble for discussion of how units are assigned to subcategories and provisions available to switch subcategories.

Comment Excerpt Number: 13

Comment: Achievement of the more stringent coal-firing CO and dioxin/furan (D/F) emission limits may not be feasible when co-firing coal with any appreciable quantity of biomass materials, such as wood chips or wood pellets, in a boiler or process heater. The proposed coal-firing CO and D/F emission limits, with no adjustment for co-firing with higher emitting biomass, would discourage, if not effectively prohibit, co-firing biomass with coal as a renewable energy alternative to fossil fuel combustion. This prohibition is in conflict with current energy, environmental, and economic programs and policies to encourage biomass combustion as an alternative to fossil fuel combustion to reduce greenhouse gas emissions and dependency on foreign oil. EPA should provide prorated emission limits for both CO and D/F from biomass and coal cofired units that would be based on the percentage of total heat input from each fuel fired.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: Within certain industry sectors, boilers are commonly used that co-fire coal in an amount greater than 10% heat input basis with at least 10% biomass. These “combination boilers” that simultaneously burn coal and biomass have different emission profiles than units that burn coal or units that burn biomass. As a result, combination boilers do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA adjust the proposed subcategory for combination boilers so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and Hg) and the biomass subcategory for purposes of regulating the combustion-based HAP (i.e., CO (as a surrogate for organic HAPs) and dioxins/furans).

As the rule is currently proposed, boilers that burn more than 10% coal with biomass will be classified in the coal subcategory. However, most boilers in this subcategory will not be able to meet the coal CO emission standard for organic HAPs due to the amount of biomass that they burn. Biomass fuels are more variable than coal and typically contain significantly more moisture than coal. As a result, it is more difficult to control combustion conditions in combination boilers than in boilers combusting only coal, which means that CO emissions from combination boilers often will be unavoidably greater than from a comparable coal-fired boiler. This makes the coal subcategory an inappropriate choice for establishing standards for combustion-based HAP. Regulating combustion-based HAP from combination boilers under the biomass subcategory makes more sense because combination boilers will perform more like biomass-fired boilers with regard to the combustion related HAPs.

Biomass typically has lower levels of metals, halogens, and mercury than coal. As a result, regulating the fuel-related HAPs from combination boilers under the biomass subcategory would be inappropriate because the amount of co-fired coal would in many cases prevent combination boilers from meeting the standards for fuel-based HAPs. For this reason, it makes more sense to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Notably, if owners or operators of combination boilers anticipate difficulty complying with the proposed CO standard, they may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. This unintended consequence of replacing biomass with coal is contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.

For both technical and policy reasons, EPA should revise the way combination boilers are regulated under the proposed rule. Combination boilers burning more than 10% coal with biomass should be subject to the same emission standards for PM/metals, mercury, and acid gases as the coal subcategory and should be subject to the biomass subcategory emission limitations for CO and dioxins/furans.

Comment: Combination Boilers – Combination coal and biomass boilers should have a CO standard based on biomass emissions.

In establishing the proposed standards, EPA has failed to accurately consider boilers that simultaneously co-fire fuels.
IECA generally agrees with this approach for HAPs that are strongly correlated with the HAP content of the fuel. However, the impact of emissions for CO and likely dioxin are based on the physical firing characteristics. We agree with EPA's rationale that boilers should be subcategorized based on their fuel type and design? however, we do not agree that all boilers are designed to burn only one fuel type and that they will encounter operational problems if another fuel type is fired at more than 10 percent of heat input. Some boilers are specifically designed to burn a combination of fuels, and to burn them in varying quantities.
In its decision making process, EPA appears to have only considered the "primary" fuel type. IECA is aware of numerous boilers for which this is not the case. Within the pulp and paper sector alone, there are at least 35 boilers, based on the survey database developed by EPA, that co-fire coal in an amount greater than 10% heat input basis with at least 10% biomass. These combination boilers that simultaneously burn coal and biomass have different emission profiles than units that burn coal or units that burn biomass. Other combination boilers burn pulverized coal or petroleum coke along with biomass in a fluid bed combustor type of boiler. According to one vendor who designs and builds boilers for this and other industries, 84 % of the boilers are designed to fire combinations of fuels at any one time. In some cases, these boilers are not able to reach full load on any single fuel. From this information it would seem that EPA has incorrectly presumed that boilers are designed based on a primary fuel. Rather, boilers can be designed to fire a variety of fuels, encompassing various types of solid, liquid, and gaseous fuels. This practice provides the most flexibility to facilities and allows them to select fuel mix based on various factors that include cost, availability, season, weather, etc.

Comment: B&W is concerned about using the EPA's proposed 10%, by heat input, to define the unit fuel type subcategories. The inherent differences in the regulated fuels can greatly impact the emissions for the fuel-related HAP's (Hg, HCI, and PM).

While we recognize the need to subcategorize by fuel type, B&W proposes that only data obtained while firing 100% of the affected fuel type be used in determination of the MACT floor limit. For example, for the biomass limit, data from the top performing units firing 100% biomass should define the biomass floor limits.

This concern is emphasized when one considers that the unit setting the Mercury limit for new units burning coal (University of Iowa - IA - EP7 Boiler 11) utilizes a data set that includes data from three different fuel blends (100% coal, 50% coal / 50% biomass, 25% coal / 75% biomass). The range of average Mercury readings for the different blends is 1.40E-081b/MBtu to 2.4E-

071b/MBtu. This clearly illustrates the importance of fuel composition and resulting mercury emissions, as there is an order of magnitude difference in emissions when firing the different blends.

Table 2 summarizes the best performing units that set proposed emission limits for new units that have significant dilution fuel blends. [See submittal for Table 2: Best performing units that reported data while firing significant dilution fuel blends.]

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: Believe that it is appropriate for EPA to continue its approach for fuel related surrogates such as HCl, PM, and mercury. It does make sense to continue to use a 10 % threshold in such situations. However, for units firing biomass in appreciable quantities it would be appropriate to establish subcategories with limits that are based on the biomass category for carbon monoxide. Combination boilers burning more than 10% coal with biomass should be subject to the same emission standards for PM/metals, mercury, and HCl as the coal subcategory since the emissions of these pollutants are fuel dependent and will be driven primarily by burning coal.

Response: See the preamble for how EPA modified the subcategories and the heat input thresholds associated with the subcategory definitions for fuel based HAP and combustion-based HAP.

Commenter Name: Robert Thornton

Document Control Number: EPA-HQ-OAR-2002-0058-2918.1
Comment Excerpt Number: 24

Comment: In addition to the concern expressed above regarding liquid fuel boilers, other subcategories should be adjusted to properly accommodate the unique characteristics of combination boilers (e.g. those burning coal and biomass, coal and gas or biomass and gas).

Some boilers co-fire coal in an amount greater than 10% heat input basis with at least 10% biomass. These combination boilers have emission profiles than units that burn coal or units that burn biomass and do not fit cleanly into either the coal-fired boiler subcategory or the biomass-fired boiler subcategory. To better accommodate the actual performance of combination boilers, we recommend that EPA adjust the proposed subcategory for combination boilers so that they belong to the coal subcategory for purposes of regulating the fuel-based HAP (i.e., metals/PM, HAP acid gases, and mercury) and the biomass subcategory for purposes of regulating the combustion-based HAP (i.e., CO (as a surrogate for organic HAPs) and dioxins/furans).

As the rule is currently proposed, boilers that burn more than 10% coal with biomass will be classified in the coal subcategory; however, most such boilers will not be able to meet the coal subcategory CO emission standard for organic HAPs due to the substantial amount of biomass that they burn. Biomass fuels are more variable than coal and typically contain significantly more moisture than coal. As a result, it is more difficult to control combustion conditions in combination boilers than in boilers combusting only coal, which means that CO emissions from combination boilers often will be unavoidably greater than from a comparable coal-fired boiler. This makes the coal subcategory an inappropriate choice for establishing standards for combustion-based HAP. Regulating combustion-based HAP from combination boilers under the biomass subcategory makes more sense because combination boilers will perform more like biomass-fired boilers with regard to the combustion related HAPs.

On the other hand, biomass typically has lower levels of metals, halogens, and mercury than coal. As a result, regulating the fuel-related HAPs from combination boilers under the biomass subcategory would be inappropriate because the amount of co-fired coal would in many cases prevent combination boilers from meeting the standards for fuel-based HAPs. For this reason, it makes more sense to regulate fuel-based HAP emissions from combination boilers under the coal subcategory.

Notably, if owners or operators of combination boilers anticipate difficulty complying with the proposed CO standard, they may have to switch away from biomass and burn more coal to be able to comply with the coal subcategory emission standards. This unintended consequence of replacing biomass with coal is contrary to national energy and climate policy, which encourages the use of more renewable biomass fuel.
Therefore, for both technical and policy reasons, EPA should revise the way combination boilers are regulated under the Industrial Boiler MACT. Combination boilers burning more than 10% coal with biomass should be subject to the same emission standards for PM/metals, mercury, and acid gases as the coal subcategory and should be subject to the biomass subcategory emission limitations for CO and dioxins/furans.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 27

Comment: Georgia-Pacific has six boilers that burn a combination of coal or petroleum coke with biomass as described below. [The submittal includes a table detailing the fuel and design of these boilers.]

All of these units, with the exception of the Big Island unit, burn more than 10% coal with the biomass and thus fall into the coal subcategory.

Boilers burning more than 5% biomass in combination with coal, liquid or gaseous fuels should be required to meet the emission levels for non-organic HAP for the coal subcategory and the organic HAP (carbon monoxide (CO) and dioxin/furan) emission limits for the biomass subcategory.

Response: Please refer to the preamble for discussion of combination fuel units.

Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 28

Comment: The non-organic HAP parameters, HCl and mercury are primarily driven by levels of these constituents in the fuels and are typically higher in coal than in biomass. Therefore, the limit for combination boilers should, as EPA envisioned in the proposed rule, be set at the coal subcategory limits.
However, organic HAP, CO and dioxin/furan, in combination boilers are less dependant on fuel constituents and much more influenced by the characteristics of the biomass being burned.

Wet biomass fuels (e.g., bark or hog fuel) have more variation in fuel quality and as such do not burn as evenly as coal. This variability results in higher CO emissions than coal combustion. At all of the facilities listed above, the biomass for these boilers are bark from the woodyard operation and purchased bark and thus have a fairly high moisture content (45% –55%). This may be even higher during rain events since the fuels are all stored in outside piles.

[Footnote 5: Elsewhere in these comments, Georgia-Pacific urges EPA to establish a particulate matter-alternative total select metals limit (TSM). Should EPA ultimately adopt this recommendation, GP notes that non-organic total select metals limits for combination boilers should be set at the coal limit for TSM.]

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 29

Comment: The amount of wood residues burned in these units varies during the day. During load swings, which are very common in these units, coal will be the first fuel to be varied with steam demand, thereby changing the ratio of coal to biomass. There may be fuel feed system problems forcing the operators to stop either fuel to the boiler. All these process swings will cause significant variation in the CO emission levels.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment: In contrast, the combination oil/gas burner design used at HOVENSA and other facilities is specifically designed so that it can fire up to 100% oil OR gas or fire both in varying quantities on the same burner. They are a completely different design than EPA contemplated in setting its standards and cannot be fairly included in the same subcategory with other units. It is noteworthy that while they were not considered in development of the MACT standards, these combination oil/gas design burners are well known in the burner industry and referenced in standard literature. See, Combustion Handbook, Volume II, pages 33-42, which devotes an entire subchapter to “Combination Gas-Oil Burners.”
There are several aspects of the co-firing design that are significant from a combustion perspective. First, when a burner is operating on both gas and oil, the gas flame can “rob” the oil gun of oxygen and result in higher CO emissions. Second, the need to fire up to 100% of the fuel in a heater or boiler as either oil or gas means that the firebox design cannot be optimized to maximize combustion efficiency. As a general rule, a firebox is designed to be about 2/3rds of

the flame height of fuel being fired. However, this is not possible in a co-fired unit, because of the different heights and characteristics of oil and gas flames:

The result is that the heater/boiler firebox configuration for co-fired unit is a compromise which does not maximize combustion efficiency or NOx emissions because it cannot be designed to do so.

Comment: Many boilers and process heaters are designed to burn multiple fuels. For units designed to burn either liquid or gas, the unit's design provides no basis for assigning the unit between two subcategories (Gas 1 and Liquid). We believe the only reasonable basis for assigning units into subcategories is what fuel they actually burn. RMA recommends using the past calendar year as the basis, with appropriate consideration of potential changes in subcategory.

Response: Please refer to the preamble for discussion of combination fuel units.

Comment Excerpt Number: 221

Comment: Boilers Are Not Always Designed To Burn One Fuel . We agree in general with EPA's rationale that boilers should be subcategorized based on their fuel type and design; however, we do not agree that all boilers are designed to burn only one fuel type and that they will encounter operational problems if another fuel type is fired at more than 10 percent of heat input. Some boilers are specifically designed to burn a combination of fuels, and to burn them in varying quantities. According to one vendor who designs and builds boilers for various industries, 84% of the boilers are designed to fire combinations of fuels at any one time. In some cases, these boilers are not able to reach full load on any single fuel. From this information it would seem that EPA has incorrectly presumed that boilers are designed based on a primary fuel. Rather, boilers can be designed to fire a variety of fuels, encompassing various types of solid, liquid, and gaseous fuels. This practice provides the most flexibility to facilities and allows them to select fuel mix based on various factors that include cost, availability, season, weather, etc. The subcategories of boilers should not be based on the fuel a boiler or process heater is designed to burn, but rather the fuel the unit actually burns.

Response: Please refer to the preamble for discussion of combination fuel units.

Document Control Number: EPA-HQ-OAR-2002-0058-3220
Comment Excerpt Number: 4

Comment: The Unique Characteristics of Combination (Biomass) Boilers.
Minnesota and national energy policy strongly encourages the use of biomass to provide energy and heat for industrial production. The forest products industry is a leader in energy generation from biomass. Unfortunately, the proposed rule will penalize boilers that co-fire coal and biomass. Because these "combination" boilers have different emission profiles from boilers that burn only coal or biomass, they don't fit into either the coal-fired subcategory or the biomass subcategory. We believe that EPA should include combination boilers burning more than 10% coal in the coal subcategory for the purpose of setting emission standards for particulate/metals, mercury and acid gases and the biomass subcategory for emissions of carbon monoxide and dioxins/furans.

Response: Please refer to the preamble for discussion of combination fuel units.

Other - Rationale for Subcategories

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council
Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 1

Comment: EPA's rationale for what it asserts are fuel- and design-based subcategories for industrial boilers, demonstrates that these subcategories actually are chosen based on the emissions characteristics of the subcategories, not on "class, type, and size" of boilers. What EPA is saying in essence is that different fuels when combusted yield different emissions characteristics – and EPA is subcategorizing to accommodate those emissions characteristics. Similarly, the Agency states that because "differences between given types of units can lead to corresponding differences in the nature of emissions and the technical feasibility of applying emission control techniques," it is justified in distinguishing between unit designs in setting standards. EPA states this is true, particularly for further subcategorizing beyond fuel type for standard setting for organic HAP emissions, for which the Agency notes "different designs and combustion systems, while having a minor effect on fuel-related HAP emissions, have a much larger effect on organic HAP emissions." 75 Fed. Reg. 32,016-32,017. But, the nature of emissions is not an element describing "class, type, or size" of boilers. Subcategorizing based on sources' emissions characteristics instead aims at the eventual achievability of the MACT floor by as many sources in the industrial category as possible – rather than standard setting based on what is achieved in practice by the best performers in the category. See NRDC v. EPA, 489 F.3d 1364, 1372 (D.C. Cir. 2007)(holding that EPA lacks authority to designate a subcategory "that allows harmful emissions in a manner contrary to Congress's statutory scheme.").

Response: EPA did not form the basis of its subcategories on emissions characteristics. Although emissions will vary by fuel type, other technical considerations were considered in the development of the subcategories including boiler design and operating limitations. For example, many commenters provided examples where combustion equipment is designed to burn fuels with a certain moisture content and as a result EPA identified a new subcategory to accommodate units that burn fuels with a hybrid grate/suspension design. See final rule and preamble for discussion of how units are assigned to subcategories and provisions available to switch subcategories.

Commenter Name: N/A
Commenter Affiliation: Sierra Club, Clean Air Task Force, Earthjustice, and Natural Resources Defense Council
Document Control Number: EPA-HQ-OAR-2002-0058-3187.1
Comment Excerpt Number: 8

Comment: EPA's Subcategorization Scheme Creates Perverse Incentives to Fuel Switch to Avoid More Stringent MACT Standards.

By defining the subcategories it has, EPA sets up incentives for existing boiler owners and operators, during the 3 year period between promulgation of final standards and compliance, to tinker with fuel mix in order to fit into the subcategory requiring the least additional controls. While the purpose of MACT at the outset is meant to be for all sources to control to the level actually achieved by the best performers, , however that performance is achieved, see Cement Kiln Recycling Coalition v. EPA, 255 F.3d 855, 861 (D.C. Cir. 2001), EPA's subcategories seem designed instead to at best perpetuate the status quo.3 The fuel-switching likely to result from EPA's subcategories (leaving aside the natural gas subcategory for which work practice standards are proposed) is likely to gravitate towards avoidance of control costs, not towards meeting the emissions performance of the best performers in the industry. In summary, EPA's proposed subcategories circumvent the fundamental objective of section 112(d), which is that "all sources in a category [will] at least clean up their emissions to the level that their best performing peers have shown can be achieved." Sierra Club v. EPA, 353 F.3d 976, 980 (D.C. Cir. 2004). EPA's scheme will motivate change, certainly, but not emissions clean up to the level of the best performing relevant sources. Moreover, where the Agency knows that fuel switching is possible and yields the best performance across the industry, subcategorizing in such a way as to provide disincentives to that compliance option runs counter to the statute's goal that MACT floor standards truly reflect the best performers. See also 42 U.S.C. § 7412(d)(2)(requiring consideration of "process changes [and] substitution of materials").

Response: EPA has consolidated many of the limits in the solid fuel subcategory for fuel-based HAP to partially address these concerns. See the preamble for further discussion of how concerns with combination boilers were treated in the final rule.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 174

Comment: EPA should provide guidance for boilers that don't clearly fit in a subcategory
EPA has established subcategories for boilers based on only a few designs and fuel types. EPA should provide guidance to facilities with other boiler designs (such as combination stoker/pulverized coal boilers and cyclone boilers) or burning fuels not described in the rule on how to determine which set of emission limits they are required to meet or include a requirement for boilers that do not fit in a subcategory to submit a case-by-case MACT analysis under 112(g) or 112(j).

Response: Sometimes a combustion unit reported more than one type of combustor design in the Survey Database, and a hierarchy was used to classify that unit in one of the combustor design categories. For coal units, the hierarchy was pulverized coal units, followed by fluidized beds and then stokers. Other designs not classified as pulverized coal, stoker, or fluidized bed were included in the stoker design category.

For biomass units, the hierarchy was units selecting both a suspension and stoker/grate firing method (excluding dry biomass units who were not believed to actually have this design given the nature of the fuel), followed by fluidized bed, followed by stokers (including sloped grate), Dutch ovens and suspension burners, and then fuel cells. Other designs not classified as stoker, fluidized bed, fuel cell, or Dutch oven, suspension burner or hybrid grate/suspension, were included in the stoker category.

Because units that were not identified to fit within one of the established subcategories were included in the coal or biomass stoker subcategories (depending on the fuel mix for which the unit was designed), units that do not fit within one of the subcategories will fall into the stoker subcategories, as appropriate. This designation impacts only the combustion-based pollutants (CO and dioxin/furan), and for the fuel-based pollutants, units will fall in the solid, liquid, or gaseous fuel subcategories as defined in the rule.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 49

Comment: For gas- and liquid-fired boilers and process heaters, subcategory assignments are proposed to be made on a unit by unit basis. This places undo operational restrictions on petroleum refinery operations where there are often gas imbalances or supply limitations. This concern can be mitigated by allowing subcategory assignments to be made on a facility-wide basis.

This additional flexibility is needed to assure compliance without restricting production and would provide for the same overall reduction of emissions. For illustration purposes, a simple example can be used. For a refinery with 2 process heaters each with a firing capability of 100 MMBTU/hr and with liquid burning capabilities, the current provision restricts each unit to firing no more than 10 MMBTU/hr of liquids on an annual average basis for assignment to the Gas 1 subcategory. However, it may be more feasible to fire oil on only one unit in a given year. If the determination were made on a facility wide basis, then one of the units could fire 20 MMBTU/hr of liquid fuel and the other unit would be restricted to firing only gas. Allowing the assignment of boilers and process heaters to be made on a facility-wide basis results in a more cost-effective rule because it allows fuel use to be optimized and improves operating flexibility.

Recommendation: Revise the gas and liquid subcategory assignment procedures to be based on whether the total facility heat duty is met by firing more than 10% liquids on an annual basis.

Response: The gas 1 subcategory has been revised to only allow burning of fuels other than gas 1 during periodic testing or gas curtailment and supply emergencies. If the units at the example facility provided in this comment are firing liquid fuels under these discrete circumstances they will still qualify in the gas 1 subcategory. The 10 percent threshold is no longer part of the gas 1 definition. For all of the other compelling reasons commenters have suggested about the different designs of the units and requests for additional subcategories, EPA disagrees that it should subcategorize on a facility instead of unit level.

Comment: Would a limited use Boiler (30 to 60 days per year) in the Gas 1 subcategory at a Major Source have to conduct an annual tune-up?

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute and National Petrochemical and Refiners Association
Document Control Number: EPA-HQ-OAR-2002-0058-0851.1
Comment Excerpt Number: 14

Comment: The large effort associated with managing unit outages and special operations to conduct the required tune-ups and performance tests has been ignored. In some cases, boilers and process units will have to be shutdown to allow burner inspections or to make repairs resulting from the inspections. In all cases, the annual tune-up or performance testing will require operating the boiler or process heater at specific high rate conditions and often with unusual feeds to meet the requirement for maximum HCl and Hg in the feed during performance tests. Significant engineering effort will be required to manage these special operations, particularly for process heaters which typically are not spared and thus the entire process will have to be run non-optimally.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Comment Excerpt Number: 3

Comment: Work practices should be more flexible to avoid impractical requirements, and CO measurement should not be required for small natural gas-fired boilers.

The proposed rule itemizes work practice requirements for Gas 1 units 10 MMBtu/hr or larger in §63.7540(a)(10)(i) – (vi). In addition, §63.7540(a)(11) references those requirements for boilers and heaters smaller than 10 MMBtu/hr. INGAA supports work practice standards for natural gas-fired units. However, additional flexibility and clarity is required to ensure that the work practices can be implemented. For example, “manufacturer recommendations” are cited in several cases, and those procedures may not be available for some existing units (e.g., older or smaller units), or operator experience may provide operating practices that are more concise and preferable to manufacturer recommendations. In addition, the many facilities include very small natural gas-fired boilers or heaters that are covered by the rule. CO measurement is not warranted for small natural gas-fired units and a “blue flame” provides adequate assurance of “good combustion”.

“Good combustion practice” standards should be appropriate for work practices. For example, this includes burner cleaning and tuning so that a clean, blue natural gas flame is evident. By requiring “manufacturer recommendations”, the practices are too limiting and additional flexibility should be provided. As needed, operator practices (in lieu of “manufacturer recommendations”) could be documented in a simple plan. In addition, flexibility should be provided for CO measurement. For example, costly reference method tests are not warranted for boiler tune ups and reasonable test procedures should be acceptable – especially since tuning measures changes in CO emissions before and after adjustments. Major source facilities often include small gas-fired heaters or boilers (e.g., for water heating), and the majority of “very small” boilers or heaters will be natural gas-fired. CO measurement is not warranted for these small gas-fired units, and a combustion tune-up that follows a subset of the steps in §63.7540(a)(10)(i) – (v) is adequate to ensure good combustion and low emissions. As noted in the text below, INGAA recommends excluding natural gas-fired (or “Gas 1”) units smaller than 10 MMBtu/hr from CO measurement. At a minimum, the rule should include a threshold of 1 MMBtu/hr for CO measurement of gas-fired boilers or heaters.

INGAA recommends the following revisions to sections (i) through (v), with proposed revisions provided here as strikethrough for deleted text and new text bold and underlined:

“(i) Inspect the burner, and clean or replace burner any components of the burner as necessary;

(ii) Inspect the flame pattern and make any adjustments to the burner necessary to optimize the flame pattern consistent with good combustion practices (e.g., a blue flame for natural gas) or the manufacturer’s specifications;

(iii) As appropriate, inspect Inspect the system controlling the air-to-fuel ratio, and ensure that it is correctly calibrated and functioning properly;

(iv) Minimize total emissions of CO emissions consistent with good combustion practices or the manufacturer's specifications. CO measurement is not required for natural gas-fired boilers or process heaters smaller than 10 million Btu per hour;

(v) Measure the concentration in the effluent stream of CO in parts per million, by volume, dry basis (ppmvd), before and after the adjustments are made. Acceptable methods include standardized test methods and procedures using a portable analyzer that follow reasonable calibration and operating practices. CO measurement is not required for natural gas-fired boilers or process heaters smaller than 10 million Btu per hour;

As an alternative to the recommended "CO measurement exclusion" text in §63.7540(a)(10)(iv) and (v), the exclusion could included in §63.7540(a)(11) as follows:

"(11) If your boiler or process heater has a heat input capacity of less than 10 million Btu per hour, you must conduct a tune-up of the boiler or process heater biennially to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section. CO measurement in (iv) and (v) is not required for natural gas-fired boilers or heaters smaller than 10 million Btu per hour."

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 70 for a response to the tune-up exemption for small capacity units. Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups. Refer to DCN EPA-HQ-OAR-2002-0058-2786.1, excerpt 15 for a response to tune-up requirements. Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: Recommendation: Instead of biennial tune-ups for units 10 MMBTU/hr or under, set a trigger based on hours of operation of the unit.

Many operations can have a boiler or process heaters that they do not use often. Requiring them to conduct a tune up at a set time period can be costly in relation to their use of the unit. Setting the trigger for requiring a tune up based on hours of operation, similar to changing your car's oil every 3,000 miles, would account for level of use. After an initial tune-up, have the following tune-up fall based on manufacturer's specifications or after 17,000 hours of operation or five (5) years, whichever comes first.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Comment: Section 63.7540(a)(10)(ii) of the proposed rule would require the owner/operator to inspect the flame pattern and make adjustments... to optimize the flame pattern. Metal process furnaces have numerous burners, some of which cannot be seen to "inspect the flame pattern". EPA should revise 63.7540(a)(10)(ii) to be required only ", if possible" or ", as applicable".

Response: In order to avoid finalizing requirements that cannot practically be met, EPA has adjusted the language to indicate “as applicable” for many of the tune-up requirements.

Comment: The proposed work practice requirement for natural gas-fired boilers and process heaters in §63.7540(a)(10)(vi)(C) would require a source to include in the on-site annual report the "type and amount of fuel used over the 12 months to the annual adjustment". In order to comply with this requirement, the facility would have to install individual gas meters on the unit. Most facilities do not presently have such meters on individual units, and installing them would be unnecessarily burdensome.
A boiler or process heater that has not operated in the previous year should be allowed to skip the annual tune-up requirements.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2711.1, excerpt 5 for a response to handheld instruments. Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Comment: The annual boiler tune-up as specified in Table 3 and as per §63.7540 (10)(iv) requires the air-to-fuel ratio be adjusted to "minimize total emissions of CO consistent with the manufacturer's specifications." Inherit to the combustion process is that any change in CO emissions will cause an inverse effect on NOx emissions. Other regulations (NOx RACT) have already been developed and are enforced to minimize NOx emissions. Penn State's existing Title V permit states that the University shall "make adjustments necessary to minimize total emissions of NOX, and to the extent practicable minimize the emissions of CO". These ideas are in conflict.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: EPA should clarify scheduling requirements and provide additional flexibility for annual and biennial tune-ups.

For work practice standards, schedule requirements for tune-ups are specified in §63.7515(e). Specifically, each annual tune-up must be conducted between 10 and 12 months after the previous tune-up. Similar timing for sources subject to biennial tune-ups is not addressed. EPA should revise §63.7515(e) to provide flexibility and address biennial tune-up timing.

In some cases, an operator may have cause to conduct a tune-up more frequently that required by the rule. INGAA believes that it is unnecessary and counter-productive for the rule to specify a minimum time of 10 months on the periodicity for annual tune-ups, as long as the maximum allowed interval is met. If a source, for whatever reason (e.g., scheduling conflicts) wants to conduct an annual tune-up sooner than 10 months after the most recent tune-up, that flexibility should be allowed. In addition, the section appears to inappropriately reference §63.7520 (which addresses stack test requirements) rather than §63.7540 for tune-up requirements. Accordingly, INGAA recommends revisions to §63.7515(e) to address this issue for both annual and biennial tune-ups, with proposed revisions provided here as strikethrough for deleted text and new text bold and underlined:

“(e) If you are required to meet an applicable work practice standard, you must conduct annual performance tune-ups according to §63.7540(a)(10) or (11)§ 63.7520. Each annual tune-up must be conducted between 10 and no later than 12 months after the previous tune-up. Each biennial tune-up must be conducted no later than 24 months after the previous tune-up.”

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Comment: Proposed Work Practices for Natural Gas-Fired Boilers/Process Heaters Require Further Clarification and Revision.

Overall, the Auto Group supports EPA’s proposed work practice tune-up requirement for natural gas boilers and process heaters. In general, the proposed tune-up requirement incorporates several key references to the manufacturers’ specifications for the affected unit, which is an appropriate and reasonable approach for these types of standards. Manufacturers’ specifications provide specific guidelines for optimizing performance and efficiency of affected units. For example, any regulatory requirements that would impose a specific CO limit instead of referencing the manufacturers’ specifications could have the unintended effect of increasing NOx emissions from a particular unit thereby resulting in compliance problems with other regulatory requirements. Specifically, as is well known in engineering circles, there is an inverse relationship between NOx and CO emissions from combustion sources. In other words, if CO emissions decrease from a boiler, NOx emissions will increase. This could result in an exceedance of emission limits in state permits and other regulatory requirements. Moreover, a decrease in CO emissions can lead to a decrease in thermal efficiency as well, which will lead to an increase in fuel consumption by the unit and could have the counter effect of increasing HAP emissions from the unit. For these reasons, EPA’s proposal to rely on manufacturers’ specifications for the tune-up requirement is a technologically sound and reasonable approach.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: Clarify If The Use Of Existing Boiler Inspection Programs Satisfy Tune-Up Requirements

In the preamble, the EPA states that it has obtained information on units that reported using good combustion practices as part of the information collection effort, and that the data obtained indicates that units typically conduct tune-ups per state regulations and permits (75 FR 32025). While states like South Carolina already have a periodic boiler inspection program in place (implemented and enforced by a separate state agency), it appears from our survey of various states that the focus of those state required inspections is predominantly safety oriented and not efficiency based. Consequently, air-to-fuel ratios, the minimization of CO emissions, and the measurement of CO in the effluent stream may not be a part of typical state's tune-up inspections. The EPA should provide clear guidance in the rule on whether the existing safety boiler inspection programs are adequate to satisfy the proposed tune-up requirements.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: Work Practice Requirements in § 63.7540(a)(10) Should Allow for Handheld Analyzers.

The requirement in proposed § 63.7540(a)(10)(v) to measure the CO concentration in the effluent stream before and after adjustments are made to the unit does not appear to allow for the use of handheld analyzers and should be revised to allow for such flexibility. Current industry practice is to perform a tune-up or combustion safety audit using a handheld analyzer, and boiler manufacturers do not recommend the use of EPA reference test methods when tuning a boiler. Requiring sources to perform a full blown EPA test method for purposes of measuring CO in the effluent stream is not appropriate as it would be costly, require more time to perform, and would not provide additional or more useful real time information/data.

Other state regulatory agencies have allowed sources to use portable analyzers for purposes of complying with regulatory limits for boilers and process heaters.
Specifically, the Bay Area Air Quality Management District (BAAQMD) Regulation 9, Rule 7: Nitrogen Oxides and Carbon Monoxide from Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters (Regulation 9-7) allows for the use of a portable analyzer and includes a portable analyzer protocol. Given that portable analyzers are recognized as reliable by state permitting authorities, the Auto Group recommends that EPA amend the language in § 63.7540(a)(10)(v) to include the following underlined text:

(v) Measure the concentration in the effluent stream of CO in parts per million, by volume, dry basis (ppmvd), before and after the adjustments are made using a handheld analyzer or similar device or other method;
Not only will this amendment provide greater flexibility, but it will also reduce the costs associated with the tune-up requirement. Tune-up costs can range from $2,500/boiler for a handheld analyzer versus $6,500-8,200/boiler for a full EPA test method. The additional cost of a full EPA test method is not justified given that handheld analyzers are just as effective in measuring CO emissions from natural gas-fired boilers and process heaters and have been recognized by state permitting authorities as appropriate tools for doing so.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: Specify Methodology To Measure CO Concentration For Tune-Up Requirement

If the EPA decides to retain the requirement that sources having to comply with tune-up requirements must measure CO concentration in the effluent stream and must maintain on-site and submit to the administrator, if requested, an annual report containing this and other tune-up information as specified in 63.7540(a)(10), the proposed rule should specify the methodology to be used in measuring CO concentration.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: EPA Should Consider Raising the Capacity Threshold for Annual Tune-Ups.

The Auto Group supports EPA’s requirement of less frequent tune-ups for smaller boilers/process heaters in lieu of emissions limits. EPA uses a heat input capacity of 10 mmBtu/hr as the threshold for requiring owners and operators of natural gas-fired boilers and process heaters to perform an annual tune-up as opposed to a biennial tune-up. [Footnote: See 75 Fed. Reg. at 32,059 (proposed §§ 63.7540(a)(10) and (11)).] While EPA explains in the preamble that work practices are appropriate for smaller boilers and process heaters that have smaller stack diameters, the agency does not explain why a heat input capacity of 10 mmBtu or less is the appropriate cut-off for requiring biennial as opposed to annual tune-ups. The Auto Group suggests that EPA consider raising the heat input capacity threshold that triggers annual tune ups to those boilers/process heaters with a heat input capacity of greater than 100 mmBtu/hr. Larger boilers (i.e., those greater than 100 mmBtu/hr) can benefit from annual tune-ups due to a more noticeable reduction in fuel use. The reduced fuel use for these larger units also results in cost savings as well as lower HAP emissions and use of this threshold heating rate would be consistent with the industrial boiler NSPS. [Footnote: See 40 C.F.R. Part 60, Subparts Db and Dc. Subpart Db covers boilers with a heat input capacity greater than 100 mmBtu/hr and Subpart Dc covers boilers with a heat input capacity from 10 mmBtu/hr through 100 mmBtu/hr.] Boilers with a heat input capacity of less than 100 mmBtu will not benefit as much from such frequent tune-ups given that experience with these smaller boilers indicates that there is rarely a change in the boiler performance from tune-up to tune-up. For this reason, EPA also should consider establishing biennial tune-ups for boilers with a capacity of 30 through 100 mmBtu/hr and every five years for boilers sized 10 to 30 mmBtu.

Response: We have not adjusted the size threshold of the tune-up to 100 mmbtu/hr in the final rule. The commenter did not provide sufficient justification that measurement of emissions is impractical at units between 10 and 100 and therefore these intermediate-sized boilers do not qualify for a work practice under 112(h). See preamble for justification of the work practice standards retained in the final rule.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group
Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 20

Comment: EPA also should consider increasing the time between required tune-ups once it is demonstrated that several consecutive (e.g., annual) tune-ups have produced minimal improvements in boiler operation as identified by decreases in CO emissions. EPA has allowed a similar kind of compliance flexibility in other regulations. For example, in the NESHAP for Steel Pickling, Subpart CCC, EPA allows the permitting authority to approve an alternative schedule for performance testing that would allow testing less frequently than annually. [Footnote: See 40 C.F.R. § 63.1161.] In addition, in the NESHAP for Primary Lead Smelting, Subpart TTT, EPA allows for less frequent testing when facilities are able to demonstrate consistent compliance with the standards. [Footnote: See 40 C.F.R. § 63.1543.] The rule allows operators up to 24 months between compliance tests if the results of the three most recent compliance tests demonstrate compliance. [Footnote: See 40 C.F.R. § 63.1543 § 63.1543(e).] EPA also allows this kind of compliance flexibility in other programs. For example, in Subpart BB of the RCRA Regulations applicable to valves in gas/vapor service, EPA permits sources to monitor valves for leaks less frequently if a leak is not detected for two successive months. [Footnote: See 40 C.F.R. § 265.1057(c)(1).] In addition, sources can skip quarterly leak detection periods for valves if a low percentage of valves are leaking. [Footnote: See 40 C.F.R. §§ 265.1062(b)(2), (3).]

EPA should apply the same testing and compliance flexibility in the final rule for boilers/process heaters that can demonstrate minimal change between annual tune-ups. Minimal change could be defined as less than a 25% change in CO emissions. [Footnote: Including a minimal threshold in the final rule will provide an incentive for assuring that the boiler is optimally tuned without the consequence of requiring a tune-up the next year if an adjustment is made in an attempt to reduce CO emissions. For example, a boiler with an initial reading of 8 ppm CO and a reading at the end of the prior year tune-up of 7 ppm CO may not necessarily be experiencing performance problems. The difference from 7 to 8 ppm CO may be caused by variations in the weather or the instrument and may not be an indication of decreased performance. The only way to verify that the boiler is at the optimal CO level is to adjust the burner. If attempts are made to tune the boiler and the CO decreases from 8 to 7 ppm CO, this should not be considered a significant adjustment which requires a tune-up in the following year. The minimal decrease from 8 to 7 ppm CO may be attributed to weather/instrument variations and not an indication of boiler performance calibration drift. If there is a significant improvement as indicated by decreased CO emissions, then the boiler should be re-visited in the following year to verify stable operations.] The Auto Group suggests that EPA insert in § 63.7540(a)(10) the following language to reflect the concepts discussed above:

If last two tune-ups performed pursuant to (a)(10) of this section did not require more than minimal (less than a 25 percent change in the CO ppm) adjustment of the burner or the air-to-fuel ratio as required by (a)(10)(ii) and (iii) of this section, the owner or operator of a boiler or process heater in the Gas 1 (NG/RG) subcategory with a heat input capacity of greater than 100 million Btu per hour shall be allowed 26 months from the last tune-up to conduct the next tune-up.

Such language would provide those sources that have boilers/process heaters that remain within unit specifications with additional flexibility as well as recognize that smaller boilers require minimal adjustments between tune-ups.

Response: The final rule does not incorporate the requested compliance flexibility for units that demonstrate that several consecutive tune-ups have produced minimal improvements in boiler operation as identified by decreases in CO emissions. The commenter did not provide sufficient justification that tune-ups conducted less frequently impact emissions. Further, technical literature provided by a Sustainable Energy Authority in Ireland relates the efficiency of a boiler to the frequency of the tune-up. Improved efficiency, reduces fuel consumption and in turn, emissions associated with fuel-based HAP. See preamble for justification of the work practice standards retained in the final rule.

Comment: A Boiler or Process Heater That Has Not Operated in the Previous Year Should Be Allowed to Skip the Annual Tune-up Requirements in §§ 63.7540(a)(10) and (11).

The proposed work practices requirement for natural gas-fired boilers and process heaters in §§ 63.7540(a)(10) and (11) do not take into account the operational status of a unit and should allow more flexibility when boilers or process heaters are not operational or have not operated in the past year. As facilities change operational practices, the operational demand for a boiler may not be present and the boiler may be kept in standby for a period of time. Thus, if a boiler is not in use, an owner or operator of the unit should not be required to startup and operate the boiler just for the sake of performing a tune-up.

The Auto Group recommends that EPA amend the language in §§ 63.7540(a)(10) and (11) to include the following text indicated in underline to address this issue:

(10) If your boiler or process heater is in either the Gas 1 (NG/RG) or Metal Process Furnace subcategories and have a heat input capacity of 10 million Btu per hour or greater, you must conduct a tune-up of the boiler or process heater annually to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section. A boiler that is not operating when the annual tune-up is due must perform the tune-up within 60 days of resuming operation.
* * *

(11) If your boiler or process heater has a heat input capacity of less than 10 million Btu per hour, you must conduct a tune-up of the boiler or process heater biennially to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section. A boiler that is not operating when the biennial tune-up is due must perform the tune-up within 60 days of resuming operation.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Comment: The costs for initial tune-ups and energy audits were annualized over 5 years. We do not believe it is appropriate to annualize these costs over a period of years, as these are services, and they must be paid in year 1 to the individual or company performing the work.

Response: EPA considers it appropriate to annualize the cost of a tune-up because the initial tune-up involves more costly steps that make subsequent tune-ups less costly. This is discussed in the docketed memorandum Revised Methodology for Estimating Control Costs for Industrial,

---

Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 34

Comment: The proposed tune-up frequencies should be relaxed.

Table 3 of the proposed rule would require a tune-up every two years for boilers and process heaters under 10 mmBtu/hr(we note this table states only boilers required tune-ups – we assume EPA intends for process heaters to also subject to this requirement) and annually for units over 10 mmBtu/hr. Given the huge number of these units and the very small potential CO emissions, we believe these frequencies should be relaxed to once every 5 years for units smaller than 10 mmBtu/hr and to biennially for units over 10 mmBtu/hr. One problem with requiring annual tune-ups is that this requirement is likely to interfere with scheduled maintenance outages and force a shutdown earlier than otherwise needed. Also, some units are not used continuously and the requirement should be changed to require these tune-ups after so many operating hours, rather than so much elapsed time.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Comment: The proposed requirement to minimize CO emissions during the tune-ups will conflict with many units' requirement to meet NOx emission limits.

§63.7540(a)(10)(iv) requires that the CO emissions be minimized consistent with manufacturer's specifications. First, many units are so old, there will be no manufacturer's specifications. Second, many units perform periodic tune-ups to minimize NOx as part of RACT requirements. It is well known that CO and NOx emissions are generally inversely related.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups. Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment Excerpt Number: 36

Comment: The tune-up requirements should allow use of portable analyzers that measure on a wet basis.

§63.7540(a)(10)(v) requires measurement of the CO & O2 concentration in parts per million, dry basis in the effluent stream. EPA should specify it is permissible to use a portable electrochemical analyzer that meets EPA Method CTM-034. This will measure CO, O2, & NOx from stationary combustion sources. However, it does not measure on a dry basis, but we see no reason for this to be a requirement. At one Eastman facility, it's Title V permits already require use of this method for periodic monitoring to measure NOx on our four NSPS Subpart D boilers. This would be a less expensive method of determining the CO concentration than having to hire a testing contractor.

Eastman requests that the moisture removal system described in this method be allowed as measurement on a dry basis.

Response: EPA agrees that the measurements do not need to be conducted on a dry basis, and that language has been removed from the rule so that the types of portable monitors mentioned by the commenter, as well as other portable monitors, can be used in the tune-up process.

Comment Excerpt Number: 112

Comment: We believe proposed §63.7540(a)(10)(i)-(iii) reflect typical tune-up activities. Many jurisdictions require annual boiler inspections for safety reasons and boilers are often spared or can be shutdown when weather conditions are mild. Some jurisdictions require such inspections for process heaters particularly as part of a NOx minimization effort. However, not all boilers and few process heaters can be readily shutdown. The proposed (a)(10)(i) and (ii) burner inspections could require such a shutdown, since burners are not always retractable and cannot always be inspected or cleaned with the process heater in service. In those cases where the boiler or process heater is not spared or cannot be shutdown without impacting steam or process heat consumers this requirement should allow for delaying the burner inspection until the unit can be shutdown without impact. Potential unit and process shutdowns were not considered in evaluating the tune-up emissions impacts, costs or burdens and are not justified. EPA should clarify that boiler and process heaters need not shutdown to accomplish the required inspections or to clean burners. For units such as process heaters that do not shut down for extended periods of time, scheduling flexibility must be provided so that tune-ups can be done in association with normal inspection/overhaul schedules. For example, in the GHG Reporting rule, EPA allows for postponing initial or subsequent calibrations until the next scheduled maintenance outage (40 CFR 98.3(i)(6), 74 Fed. Reg. 56381). A similar approach should be used for scheduling of tune-ups on equipment which does not lend itself to an annual frequency.

Response: EPA agrees with the commenter. As long as owners/operators complete the parts of the tune-up that can be completed, they can postpone impractical requirements until the next scheduled outage, whichever comes first.

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 113

Comment: Proposed §63.7540(a)(10)(iii) requires "Inspect the system controlling the air-to-fuel ratio, and ensure that it is correctly calibrated and functioning properly." This wording presumes an automatic air-to-fuel ratio controller, but those are present on a minority of process heaters. Where metered fuel/air control systems with O2 trim is installed, there is no real need for periodic "tune-ups" since combustion is continually optimized. Rather, burner/combustion system inspections, control equipment calibrations, and operational checks are all that should be needed to verify proper operation. EPA should reword the work practice requirements so that sources have flexibility to adapt procedures as most applicable and appropriate for specific sources.

Many units only have automatic draft control and individual, manual burner air control. For smaller units, draft control may be manual. Adding automatic air-to-fuel controls, as this requirement might be interpreted to require, is a very large, unjustified cost for units that do not have it, because it requires adding a forced draft combustion air system and perhaps an induced draft system. No such step was considered in the record and it is not justified.
EPA should reword §63.7540(a)(10)(iii) as follows "Inspect the draft control and burner air control systems to ensure they are operating properly. Inspect the system controlling the air-to-fuel ratio, if any, and ensure that it is correctly calibrated and functioning properly."

Response: EPA agrees with the commenter that air-to-fuel ratio controllers were not envisioned as a requirement for all units. Therefore, EPA is amending the language in §63.7540(a)(10)(iii) to require affected sources to inspect the ratio, as applicable. Refer to DCN EPA-HQ-OAR-2002-0058-2786.1, excerpt 15 for a response to tune-up requirements.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 114

Comment: Proposed §§63.7540(a)(10)(iv) and (v) are not typical tune-up requirements for either boilers or process heaters and do not reflect MACT. State tune-up requirements require minimization of NOx, not CO. Thus, these subparagraphs do not reflect the State requirements and would violate the State tune-up requirements for minimizing NOx. Additionally, the tune-up requirement conflicts with the proposed energy assessment work practice requirements, because tuning a boiler or process heater for minimum CO generally requires increasing excess air, which increases energy consumption, in direct conflict with the energy assessment directive to decrease energy consumption.

If the draft control on a boiler or process heater is working properly, as (a)(10)(iii) confirms, and there are no mechanical problems with the flame pattern, as (a)(10)(ii) confirms, there is no justification for measuring CO, since CO will be very low when these items are operating properly and because these are the things you would check and correct if CO were high. Furthermore, the mass of POM emissions that might be reduced from a gas fired boiler or process heater is insignificant. These CO measurement requirements should be removed. If they are not removed they must be justified versus the NOx emissions increase they will engender and EPA must consider policy implications and legality of whether the rule can specifically override State requirements to minimize NOx. The O2 level in a boiler or process heater also must consider draft limitations, flame impingement, and flame stability to assure a safe, reliable and efficient operation, and these conditions are not recognized in the EPA tune-up procedure.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO. Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 117 for a response the definition of a tune-up.

Comment: If burner/control adjustment relative to CO emissions is maintained in the tune-up procedure, the following changes are needed to reflect EPA's description of this work practice, the Agency cost and burden estimate, to make the CO adjustment practical, and not to have it result in increased NOx and other emissions.
i. It should be clarified, in regulatory language, that the CO is only to be minimized to the extent the adjustments do not increase NOx emissions, decrease unit combustion efficiency, cause flame impingement or flame instability, or cause other safety issues, and that portable CO and O2 analyzers are acceptable, and that these tests are not performance tests. Further, it should be made clear that the tuning is to be done at a single representative operating rate. Neither the rulemaking record nor combustion principles justify multipoint tune-ups, especially when some units basically operate at a fixed rate.
ii. For a short term adjustment situation, unit firing and stack conditions will not change enough for the stack moisture to vary significantly. Comparing CO measurements on either a wet or dry basis, before and after adjustment, is more than adequate to reflect the impact of adjustments.

iii. The oxygen measurement should be specified to be based on either an O2 CEMS reading, if the unit has one, or measurement using a portable emissions monitor. It should be made clear that a Method 3 oxygen measurement is not required.
EPA should not finalize proposed §§63.7540(a)(10)(iv) and (v). If these requirements are maintained, they should be simplified and clarified as discussed in items i – iii, above and EPA must specifically over-ride State tune-up requirements to minimize NOx and/or O2.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO. Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: Proposed §63.7515(e) requires that annual tune-ups be performed between 10 and 12 months after the previous tune-up. This means the tune-ups will be more frequent than on an annual basis, a fact not reflected in the record, and will make compliance difficult, because the source will not be able to do the tune-up at the same time each year. For instance if a tune-up is done in May one year, it must be done in April or May of the following year. Since good practice requires some allowance for problems and possible delay due to process operation issues, prudent sources will perform the tune-up in April. Then the next year's tune-up would be in March, etc. Under the proposed system, the work practice is actually required more frequently than annually, a fact not reflected in the record or cost analyses, and obviously not justified. We suggest §63.7515 be revised to specify that annual tune-ups may be done at any time in the same calendar quarter as the initial tune-up was done, regardless of the particular month in which the tune-up occurred. If a boiler or process heater does not operate during the quarter, the tune-up should be required within 30 days after restart.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 81 for a response to scheduling of tune-ups.

Comment Excerpt Number: 117

Comment: The definition of "Tune-up" is provided on 75 Fed. Reg. 32065. It correctly stipulates "optimize the combustion efficiency," whereas language noted above in 7540(a)(10) requires "minimize total emissions of CO," which as noted above is an incorrect approach to a tune-up and will lead to lower efficiency and higher net total emissions. As indicated above, EPA needs to correct language in 7540.

Response: The definition of "Tune-up" was removed from 40 CFR 63.7575 because all of the requirements for a tune-up are provided in the rule language at 40 CFR 63.7540(a)(10), making the definition unnecessary.

Comment: The "tune-up" definition implies that use of an approved specialist could be required. EPA needs to recognize that many companies have in-house resources who are already well qualified, and already do perform adjustments to burner systems. Continued use of these resources must be supported.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups.

Comment: We support inclusion of a biennial boiler tune-up requirement in the rule for applicable small (less than 10 million Btu input per hour) boilers as a means to enhance energy efficiency (and specifically combustion efficiency) and reduce toxic HAP emissions. We suggest clarification as to whether the proposed rule would require tune-up solely of the combustion systems of boilers or of the entire boiler (or furnace) system. We recommend the broader form of tune-up, which would allow additional efficiency measures to be addressed beyond combustion control.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2938.1, excerpt 1 for a response the inclusion of work practices. Refer to DCN EPA-HQ-OAR-2002-0058-2921.1, excerpt 1 for a clarification of the tune-up requirements.

Comment Excerpt Number: 3

Comment: INVISTA, like other chemical manufacturers, has process heaters that are in dedicated service to specific chemical manufacturing process units, which are intended to run up to approximately three years between scheduled maintenance turnarounds. On a regular basis and consistent with process safety regulations, standards, and good operating practices, these heaters are inspected and any required preventative maintenance is performed at the end of these multi-year process runs during the scheduled unit turnaround. The proposed requirement to complete an annual tune-up would place facilities in the position of having to shut down an entire production unit to complete the heater tune-up. These more frequent production unit shutdowns and subsequent startups will result in additional emissions from the production unit (e.g., due to vessel purges). In addition to potentially generating additional emissions, process unit startups and shutdowns present the greatest safety risk to plant personnel. Adding startups and shutdowns, therefore, could increase the overall safety risk at these plants.

Recommended Text at 63.7540(a)(10):
If your boiler or process heater is in either the Gas 1 (NG/RG) or Metal Process Furnace subcategories and have a heat input capacity of 10 million Btu per hour or greater, you must conduct a tune-up of the boiler or process heater in each calendar year in which the unit operates annually, or at the next scheduled unit turnaround, to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Commenter Name: Walter Tyler
Commenter Affiliation: Invista
Document Control Number: EPA-HQ-OAR-2002-0058-2761.1
Comment Excerpt Number: 4

Comment: In addition, with respect to Item 2 in Table 3, the possibility exists for an affected unit to be in the site's Title V operating permit, even if it does not run during a calendar year. In this case, the intent of this requirement would be met if the unit is allowed to conduct the required tune-up during the next calendar year in which the unit operates. Without this modified language (see below) a site could be required to start an affected unit for the sole purpose of conducting the annual tune-up. As stated above, these additional startup and shutdown periods could result in increased emissions and increased overall safety risk at the facility. Accordingly, INVISTA suggests that the language in Item 2 of Table 3 be modified as follows:

Recommended Text at Table 3, Item 2:
Conduct a tune-up of the boiler in each calendar year in which the unit operates annually, or at the next scheduled unit turnaround, as specified in § 63.7540

Response: We have not modified the language in Table 3, but have made some exceptions in § 63.7540 to the annual and biennial frequency to account for units with continuous processes that exceed these time frames. EPA has also incorporated a biennial tune-up frequency for limited use units. The fact that these units operate for unpredictable periods of time and limited hours, would require units to start up solely for the purposes of implementing a tune-up, which is economically impracticable, and would lead to increased emissions and combustion of fuel that would not otherwise be combusted. Therefore, we are regulating these units with a work practice standard that requires a biennial tune-up, which will limit HAP by ensuring that these units operate at peak efficiency during the limited hours that they do operate.
EPA agrees that a unit that is not operating should not be started up for the express purpose of conducting a tuneup. To ensure that tune-ups are as effective as possible and do not result in excess emissions, for units that are not operating on the required date for a tune-up, the tune-up must be conducted within one week of startup.

Document Control Number: EPA-HQ-OAR-2002-0058-2761.1
Comment Excerpt Number: 5

Comment: Many combustion units have manufacturer's specifications. However, older units may not have written manufacturer's specifications available. In these cases, best practices have been developed by combustion unit experts. It is important to allow the use of these best practices when tuning older units.

Recommended Text at 63.7540(a)(10)(iv):
Minimize total emissions of CO consistent with the manufacturer's specifications, where available, or consistent with unit-specific best practices for operation of the unit.

Response: Because manufacturer's specifications may not be available for all units and because of unique design considerations that may impact a given units ability to meet the specific tune-up requirements, the language in 63.7540(a)(10)(i) through (iv) has been amended.

Commenter Name: Walter Tyler
Commenter Affiliation: Invista
Document Control Number: EPA-HQ-OAR-2002-0058-2761.1
Comment Excerpt Number: 6

Comment: There is no language addressing how this measurement should be completed. We request specific language to provide clarity and certainty of compliance obligations. When boiler/process heater tune-ups are conducted, handheld instruments are often used by the boiler/process heater experts. Specifying that handheld instrumentation is acceptable to meet this requirement would provide the necessary clarification and would meet the intent of this provision. Requiring a complete Method 10 test, on the other hand, would add significant additional cost without any additional improvement in the tune-up results. Specifically, such testing would require mobilization of a stack testing firm before the tune-up and after the tune-up in order to meet the requirement.

Recommended Text at 63.7540(a)(10)(vi)(A):
The concentrations of CO in the effluent stream in ppmvd, and oxygen in percent dry basis, measured (using handheld combustion gas analyzers or other measurement instrumentation) before and after the adjustments of the boiler.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: Units of this size may not be operated, even within a two-year period. For consistency with the larger Gas 1 unit requirements, we recommend the following revisions:

Recommended Text at 63.7540(a)(11):
If your boiler or process heater has a heat input capacity of less than 10 million Btu per hour, you must conduct a tune-up of the boiler or process heater during each rolling biennially period in which the unit operates to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section. If the affected unit is part of a process that has longer than a two-year period between scheduled turnarounds, the tune-up shall be completed at the next scheduled turnaround.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Commenter Name: William R. Ermatinger
Commenter Affiliation: Northrop Grumman
Document Control Number: EPA-HQ-OAR-2002-0058-2506.1
Comment Excerpt Number: 13

Comment: The tune-up procedure described in proposed §63.7540 requires minimization of CO emissions as an intended means of minimizing HAP emissions, because EPA proposes to utilize CO as a surrogate for HAPs. However, adjustment of boilers or process heaters with a focus of minimizing CO emissions usually results in suboptimal performance with respect to fuel efficiency, steam generation rate and cost of operation, thereby wasting fuel and increasing emissions of other pollutants, including the other HAPs to be regulated under the Boiler MACT, and also the recently regulated greenhouse gases. Because the typical level of CO at the point of highest operating efficiency is not significantly higher than at its minimized level, adjustment of CO to a minimum level without regard to other desirable aspects of operation as proposed is unwarranted.

Response: In the final rule we have modified the requirements of the tune-up to optimize CO emissions instead of “minimize” CO emissions in order to balance the concerns of flame instability and increased NOx emissions. This approach is consistent with most state tune-up programs and manufacturer specifications, which suggest minimizing NOx emissions while optimizing other aspects of the combustion system.

Commenter Name: William R. Ermatinger
Commenter Affiliation: Northrop Grumman
Document Control Number: EPA-HQ-OAR-2002-0058-2506.1
Comment Excerpt Number: 14

Comment: The point of highest boiler efficiency generally occurs at a particular boiler load and steam output. Deviating from this point will result in less than peak efficiency, but continuous operation at the peak efficiency point is not usually practical because of routine load variations. Only "base loaded" boilers have the potential to be operated at a relatively steady state, but even base loaded units must be designed to "float" with changing steam demands in an industrial environment.

Response: EPA is mindful of the need to account for sources’ variability and the practical impact boiler load has on combustion efficiency. However, the annual and biennial tune-ups requirements will adequately ensure combustion efficiency is maintained in discrete intervals. The tune-up requirements are not mandating a continuous operation at peak efficiency.

Commenter Name: William R. Ermatinger
Commenter Affiliation: Northrop Grumman
Document Control Number: EPA-HQ-OAR-2002-0058-2506.1
Comment Excerpt Number: 17

Comment: As such, these requirements are outside the scope of EPA’s authority under §112(d) of the CAA and should be removed in entirety from the proposal. A more viable approach to assuring lowest HAP emissions of an industrial boiler over the long term would be to establish the most efficient operating range and then utilize the same parameters monitored by the control system as surrogate parameters for HAP minimization.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Commenter Name: William R. Ermatinger
Commenter Affiliation: Northrop Grumman
Document Control Number: EPA-HQ-OAR-2002-0058-2506.1
Comment Excerpt Number: 18

Comment: The requirement for additional certified energy assessments and tune-ups adds an unnecessary cost and administrative burden. Large industrial facilities already manage their boiler efficiency as a routine cost control technique. Adding an additional administrative burden and cost will not serve to significantly improve the existing processes.

Response: The EPA agrees that some sites already perform regular tune-ups, which means the requirement will not increase costs for those facilities. Based on data received from the ICR survey, not all units reported annual tune-ups as part of a good combustion practice and EPA determined that regulating the frequency and components of the tune-up would maximize combustion efficiency in this source category.

Commenter Name: Robert D. Morrison
Commenter Affiliation: Abbott Laboratories
Document Control Number: EPA-HQ-OAR-2002-0058-2764.1
Comment Excerpt Number: 22

Comment: Greater flexibility should be provided on the timing and use of tune-ups as work practices for small boilers and Gas 1 boilers (40 CFR 63.7515(e), 75 FR 32052). Section 63.7515(e) requires a tune-up interval of 10 to 12 months from the previous tune-up. This could result in more frequent tune-ups than the nominal “annual” frequency over time. As an alternative, scheduling for tune-up should be allowed to vary within a range that includes a shorter and longer period (e.g. between 10.0 and 14.0 months), or simply require a tuneup during each calendar year. This would allow flexibility to coordinate shutdowns for tuneups among multiple units and ensure availability.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Commenter Name: Donald R. Schregardus
Commenter Affiliation: Department of Defense
Document Control Number: EPA-HQ-OAR-2002-0058-2763.1
Comment Excerpt Number: 22

Comment: The requirement to conduct annual tune-ups of gas-fired boilers (heat input capacity of 10MMBtu/hr or greater) does not include a qualification whereby limited-use boilers would be required to conduct tune-ups less frequently than normal operational boilers. The consequence of this is that boilers that operate only in a back-up capacity would be required to undergo annual tune-ups despite operating zero hours or only a few hundred hours during the year. The resultant unintentional effect of universally applying the tune-up requirement is that HAP emissions will unnecessarily increase due to operating boilers solely for the purpose of conducting a tune-up.

At some military bases, over 50% of natural gas boilers of heat input capacity of 10 MMBtu/hr or greater are considered limited-use boilers, having an annual heat input capacity factor equal to, or less than, 10%. Several of these boilers typically will not be operated at all during the year due to being designated for back-up use only or for lack of system demand. Operating these boilers for the sole purpose of conducting annual tune-ups will increase HAP, criteria pollutant, and greenhouse gas emissions while consuming fuel and resources with no environmental benefit. Boiler manufacturers provide specifications for achieving optimum operational efficiency. Because boiler manufacturer recommendations may vary, language is being proposed to address limited-use boilers.

Add the following language at §63.7540(a) to the rule to address limited-use boilers.
The following Boiler MACT criteria shall apply for limited-use boilers to assure that the maximum degree of HAP reduction is achieved:

a. Limited-use gas boilers (heat input capacity of 10 million Btu per hour or greater) having an annual heat input capacity factor equal to or less than 10%, may conduct a tune-up biennially provided the owner or operator conducts monthly calculations to demonstrate that the boiler maintains limited-use status on a 12-month rolling basis.

b. If any limited-use gas boiler (heat input capacity of 10 million Btu per hour or greater) fails to maintain limited-use status on a 12-month rolling basis and a tune-up has not been completed in the previous 12-month period, then the owner or operator shall conduct a tune-up of the gas boiler within the next 90 day period following the month that the boiler fails to maintain limited-use status.

c. Gas boilers of any size that do not operate for any period of time during a biennial period shall not be required to conduct a tune-up for that same biennial period. Following the .first biennial period in which a gas boiler did not operate for any period of time, the owner or operator shall conduct a tune-up of the gas boiler within the next 90 day period following the first restart of the gas boiler.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Commenter Name: W. Randall Rawson
Commenter Affiliation: American Boiler Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2698.1
Comment Excerpt Number: 23

Comment: * ABMA acknowledges the proposed requirements for boiler tune-ups set forth in proposed 40 C.F.R. 63.7540(a)(10). While maintenance, repair and tune-up of boilers and combustion equipment in the >400,000 Btu/hr sector do have characteristics in common, ABMA notes that every boiler system is different depending on overall design, operational characteristics and use. Each boiler system in this sector is designed to a specific application; “cookie-cutter” designs do not apply to the non-residential boiler sector. Given such variability in design and operation, and the very real issue of safety as it pertains to (1) doing work with highly technical combustion systems and (2) operating those systems post-tune-up, it is important for tune-ups to be conducted by companies and personnel with the highest standards of technical training and practical expertise in addressing issues of maintenance, repair and optimization of boiler systems. The manufacturers of boilers, burners, or boiler components are a logical source of expertise, as are representatives and boiler repair companies that have documented arrangements with manufacturers. Further, tune-ups should be conducted in accordance with manufacturer guidelines and recommendations in order to preserve technical warranties and guarantees.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer’s specifications and tune-ups.

Commenter Name: Melvin E. Keener
Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)
Document Control Number: EPA-HQ-OAR-2002-0058-2824.1
Comment Excerpt Number: 25

Comment: CRWI supports the use of a periodic tune-up-as a work practice for gas-fired boilers. However, we would suggest that the schedule be made more flexible.

The tune up must be done when the unit is shut down. While some facilities shut down their unit for maintenance on an annual basis, others have maintenance cycles of 36 months or more, depend upon the facility’s production schedule, the boiler design, the fuel used, the load for that boiler and the annual hours of operations. Some facilities will have multiple boilers and only use part of them at any time Requiring a facility that has not been used in that calendar year to undergo an annual tune-up does not make sense.

Therefore, CRWI suggests that the Agency modify the timing for this requirement to match a facility’s routine maintenance schedule. There is no reason to develop a rigid schedule for something when a flexible schedule based on routine maintenance will be equally effective. CRWI suggests the following modifications to § 63.7540(a)(10) and Table 3.

63.7540(a)(10): If your boiler or process heater is in either the Gas 1 (NG/RG) or Metal Process Furnace subcategories and have a heat input capacity of 10 million Btu per hour or greater, you must conduct a tune-up of the boiler or process heater in each calendar year in which the unit operates-annually, or at the next scheduled unit turnaround, to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section.

Table 3, Item 2:
Conduct a tune-up of the boiler in each calendar year in which the unit operates annually, or at the next scheduled unit turnaround, as specified in § 63.7540

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Commenter Name: Chris Greissing
Commenter Affiliation: Industrial Minerals Association
Document Control Number: EPA-HQ-OAR-2002-0058-2740.2
Comment Excerpt Number: 30

Comment: (e) If you are required to meet an applicable work practice standard, you must conduct annual performance tune-ups according to 63.7520. Each annual tune-up must be conducted between 10 and 12 months after the previous tune-up.

Conducting a tune-up would require a boiler outage. Annual outages are scheduled based on numerous business factors and can occur at a different time each year. This would make the narrow requirement of 10-12 months between tune-ups unnecessarily onerous and costly. Additionally, backup boilers may only operate a limited number of hours in any given year. It is impractical to conduct an annual tune-up on a unit that has operated 2500 hours since its last tune-up, for example. Therefore, the tune-up frequency should be based on the following criterion: once per calendar year but not sooner than at least 6000 hours of operation between tune-ups. This would require boilers operating on a continuous basis to undergo a tune-up once per calendar year but with separation between tune-ups of at least 6000 hours of operation. For backup units a tune-up would be required some time during the calendar year after the unit reached 6000 hours of operation since its last tune-up.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 70

Comment: Since there is no minimum design firing rate specified, tune-ups would be required for even the smallest boiler or process heater at a major source, such as those designed for laboratories, cafeterias and offices. Even the smallest boiler used for space heating would be covered. The proposal would even require tune-ups, permitting and similar burdens for such small units as laboratory and cafeteria steam generators, steam cleaners (e.g., carpet cleaners), gas-fired oil fryers for food and similar insignificant sources. The database supporting this rulemaking did not consider such small boilers and process heaters, nor did the cost and burden estimates consider them. Applying the tune-up requirements and the recordkeeping and reporting requirements to them will provide no benefit, and they should be excluded.

The State rules on which the tune-up requirement claimed to be based typically only apply the tune-up requirement to boilers and process heaters above a certain size. For instance, South Coast rule 1146 and N.J.A.C. 7:27 19.7 require combustion tune-ups for boilers and process heaters over 5 MMBTU/hr design firing rate.

Recommendation: Specify a 5 MMBTU/hr minimum design heat input capacity for making any of the requirements of this proposal applicable including notice and general provision requirements.

Response: EPA disagrees with incorporating a de-minimus level on the tune-ups. EPA expects many facilities will consolidate the recordkeeping system and implementation of tune-ups in order to reduce the costs of recordkeeping. Further, many boiler manufacturers recommend annual servicing of the unit. Similarly, small units located residential areas, such as home furnaces and boilers have similar recommendations for annual tune-ups in order to maintain good efficiency and safe use of the unit. The commenter does not provide sufficient justification why a routine tune-up of these small industrial/institutional/commercial boilers is an unreasonable requirement.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 71

Comment: EPA provides justification (not economically feasible) for units of ?10 MMBTU/hr to be subject to biennial tune-up requirements rather than annual. We believe that the EPA analysis actually underestimates the cost and overestimates the potential emission reductions and that the case for exempting small units from annual tune-up requirements is even stronger than EPA indicates. On that basis, we believe units < 100 MMBTU/hr should be subject a no more frequent tune-up requirement than biennial and that units < 10 MMBTU/hr should not be subject to the requirement at all. Emission reduction potential is overestimated because EPA overestimated the potential for problems in boilers and process heaters burning the clean Gas 1 fuels and because the Agency did not account for the increases in emissions that result from upsetting the boiler or process heater while inspecting the burner(s). Costs are higher than EPA estimates for the following reasons. We believe a realistic evaluation would show that such a requirement has negligible emissions impact

* EPA mistakenly assumed one burner per unit.

* EPA did not account for the cost and effort in accessing the burner(s) in forced air units.

* EPA did not account for the stack access costs or the moisture measurement cost.

* EPA did not account for the cost of determining stack moisture or the costs that come from making the tune-up as a performance test (as discussed in Comments V.5 and V.6.)

Recommendation: Change the tune-up frequency to biennial for units of <100 MMBTU/hr and eliminate the tune-up requirement for units under 10 MMBTU/hr.

Response: In the final rule EPA has adjusted the language to indicate "as applicable" for many of the tune-up requirements. EPA has also modified the CO measurement basis to remove the requirement to measure stack moisture, as long as all measurements of CO are made on the same basis. EPA has also made certain exceptions to the schedule of tune-ups for units who have two or 3 year continuous processes in order to avoid increased emissions from upsetting these boilers while they are in mid-process. As a result, many units identified in the proposal as requiring certain aspects of a tune-up will not realize these costs. Furthermore, EPA disagrees that the emission reductions have been overestimated. EPA expects work practice standards such as boilers tune-ups will improve the efficiency of boilers, resulting in fuel savings and pollution prevention. EPA has determined that boiler tune-up improve the efficiency of a boiler 1 percent; this conservative estimate was extracted from the technical literature.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 73

Comment: Annual tune-ups intended to minimize CO emissions are proposed for existing boilers and process heaters with a design heat duty of >10 MMBTU/hr that fire Gas 1. Biennial tune-ups are required for units with a design heat input <10 MMBTU/hr regardless of what type of gas they combust. We do not believe such tune-ups are MACT, as EPA claims on Page 32025 of the proposal preamble. The basis for EPA's conclusion that a tune-up for minimizing CO is MACT is the claim that many States require tune-ups. While this is correct to some extent, these State tune-ups typically are for the purpose of minimizing NOx or optimizing combustion by minimizing O2 and do not require minimizing CO as EPA proposes. In fact, reducing CO using the tune-up procedure EPA proposes would violate the very tune-up requirements EPA cites, because reducing CO increases NOx and requires increasing O2. As we discuss in our next comments, it isn't even clear that the proposed tune-up would reduce any annual emissions, since the tune-up itself raises emissions while it is being done. Thus, while we believe a simple, non invasive inspection work practice might add some value and meet the requirements of 112, the proposal to use the tune-up to minimize CO emissions should not be finalized as presented.

Recommendation: Do not finalize proposed 63.7540(a)(10)(iv) and (v). If these requirements are maintained, they should be simplified and clarified and EPA must specifically override State regulations that require minimizing NOx and/or O2 or optimizing combustion efficiency.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: The true impacts of the 63.7540(a)(10)(i)-(iii) inspections should be characterized and documented by the Agency in the record. The evaluation in the proposal record seems to assume each unit has one or two burners that are readily inspected. This may be true for some units, particularly boilers and some smaller process heaters. But many units, particularly larger process heaters, have a multitude of individual burners (tens to hundreds), and these are often not easily accessible for inspection, such as in the case of forced combustion air systems, where duct work limits easy access. For those units, costs and burdens will be much higher than EPA estimates because of the vastly higher number of burners to inspect and the added cost and effort of opening ductwork to allow the inspection.

Recommendations: Adjust the estimated costs for the tune-up work practice and reevaluate its justification.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 71 for a response to underestimated tune-up costs.

Comment: Proposed 63.7540(a)(10)(iii) requires "Inspect the system controlling the air-to-fuel ratio, and ensure that it is correctly calibrated and functioning properly." This wording presumes an automatic air-to-fuel ratio controller, but those are present on a minority of process heaters. Many units only have automatic draft control and individual, manual burner air control. For smaller units, even draft control may be manual. Adding automatic air-to-fuel controls, as this requirement might be interpreted to require, is a very large, unjustified cost for units that do not already have it because it requires adding a forced combustion air system and perhaps an induced draft system. No such step was considered in the record.

Recommendation: Reword 63.7540(a)(10)(iii) as follows "Inspect the draft control and burner air control systems to ensure they are adjusted and operating properly. Inspect the system controlling the air-to-fuel ratio, if any, and ensure that it is correctly calibrated and functioning properly."

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 113 for a response to flexibility with respect to an air-to-fuel ratio controller.

Comment: Proposed 63.7540(a)(10)(iv) and (v) are not typical tune-up requirements for either boilers or process heaters and do not reflect MACT, and their significant costs are not reflected in the rulemaking record. As we pointed out in Comment V.C.1, State tune-up requirements typically require minimization of NOx or optimization of combustion efficiency, not minimization of CO. Thus, these subparagraphs do not accurately reflect the State requirements, are not MACT and would, in fact, violate the State tune-up requirements for minimizing NOx. Minimizing CO would require units to operate at less efficient higher excess O2 levels. Additionally, the tune-up requirement conflicts with the proposed energy assessment work practice requirements, because tuning a boiler or process heater for minimum CO increases energy consumption, in direct conflict with the energy assessment directive to decrease energy consumption.

Both paragraphs require that the source have or contract for CO and O2 monitors [Footnote: We presume this is the Agency intent in these requirements, though the language in propose d63.7515 and 63.7520 could be read as requiring a Method 10 performance test for these before and after measurements. This point should be clarified in the record and any final version of the rule which includes this requirement.] and (a)(10)(v) requires a moisture measurement on the stack gas. As discussed in other comments, these CO measurements appear to be treated as performance tests, resulting in additional costs and burdens, versus a less formal check. Costs and burdens for these measurements and their treatment as performance tests are not totally reflected in the record since it appears the significant cost of the moisture measurements, accessing the stack and performance test burdens were not included in EPA estimates. Additionally, as EPA points out in its 112(h) justification for these work practices, access to small stacks to allow such measurements isn‘t even feasible.

If the draft control on a boiler or process heater is working properly, as (a)(10)(iii) confirms, and there are no mechanical problems with the flame pattern, as (a)(10)(ii) confirms, there is no justification for measuring CO, since CO will be very low when these items are operating properly and because these are the things you would check and correct if CO were high. Furthermore, the mass of CO emissions and POM emissions that might be reduced from a gas-fired boiler or process heater is insignificant. These CO measurement requirements should be removed. If they are not removed they must be justified versus the NOx emissions increase they will engender and the rule must specifically override State requirements to minimize NOx. The O2 level in a boiler or process heater also must consider draft limitations, flame impingement and flame stability to assure a safe, reliable and efficient operation.

Comment: A. Tune-ups are defined to minimize CO, but that will decrease efficiency and Will increase overall emissions.
In the Proposed Rule, the tune-up requirements are defined in such a way to reduce CO emissions without any consideration of efficiency and costs. 75 FR 32014. Specifically, the Proposed Rule requires minimization of CO "consistent with the manufacturer’s specifications." 75 FR 32014. This practice generally requires increasing excess air, temperature, costs, and even overall HAP emissions while decreasing efficiency. Additionally, lowering CO emissions for many units will result in an increase of NOx emissions. First, many units are so old, there will be no manufacturer’s specifications. Second, many units perform periodic tune-ups to minimize NOx as part of RACT requirements. It is well known that CO and NOx emissions are generally inversely related. Hamworthy Peabody Combustion (a CIBO member) provided the figure (see submittal for combustion performance figure) to indicate the general relationship of (excess O2 from peak efficiency), CO, NOx, and combustion efficiency for a gas fired burner. This shows relative changes from the peak efficiency point and is generally applicable in form for all fuels. As shown, attempts to focus on reducing CO emissions will lead to increased excess air operation, thereby increasing NOx emissions and decreasing unit efficiency. EPA has failed to recognize this basic reality of burner operation and the negative impact on NOx and energy efficiency, and rather, in their impacts analysis, assumed a 1% improvement in efficiency (75 FR 32037). While there may be units in operation that can improve efficiency, well tuned boilers and process heaters will generally increase NOx emissions and decrease efficiency if the only focus is on reducing CO emissions. In reality, optimum conditions are achieved with CO at some higher level. CIBO recommends that EPA amend the rule so that tune-ups also consider optimizing efficiency, limiting increases of NOx, and ensuring safety, not focusing on

minimizing CO. In fact, EPA is correct in its definition of "Tune-up" in that it specifies "to optimize combustion efficiency" (63.7575). In contrast, 63.7540(a)(10)(iv) stipulates "minimize total emissions of CO." The latter needs to be changed to recognize the need for optimization in recognition of all appropriate factors.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups. Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO. Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 117 for a response the definition of a tune-up.

Comment Excerpt Number: 79

Comment: If the CO minimization portion of the tune-up is maintained, the following changes are needed to reflect EPA's description of this work practice, correct the Agency cost and burden estimate, to make the CO adjustment requirement practical, and not have the adjustment result in increased NOx and other emissions.

i. It should be clarified, in regulatory language, that the CO is only to be minimized to the extent the adjustments do not increase NOx emissions or firing or cause flame impingement or flame instability, that portable CO and O2 analyzers are acceptable, and that these tests are not performance tests. Further, it should be made clear that the tuning is to be done at a single representative operating rate. Neither the rulemaking record nor combustion principals justify multipoint tune-ups.

ii. The moisture measurement and correction requirements should be dropped. For a short term adjustment situation, unit firing and stack conditions will not change enough for the stack moisture to vary significantly. Comparing CO measurements on a wet basis, before and after adjustment, is more than adequate to reflect the impact of adjustments. The Method 4 moisture tests called for in the present proposal would impose a more than $10,000 cost per tune-up, a cost not considered in the Agency cost and burden analyses.

iii. The oxygen measurement and correction should be specified to be based on either an O2 CEMS reading, if the unit has one, or measurement using a portable monitor. It should be made clear that a Method 3 oxygen measurement is not required.

iv. All suggestions that the tune-up is a performance test should be removed.

Recommendation: Do not finalize proposed 63.7540(a)(10)(iv) and (v). If these requirements are maintained, they should be simplified and clarified as discussed in items i iv, above, and EPA must specifically over-ride State requirements to minimize NOx and/or optimize combustion.\

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO. Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: EPA should acknowledge that portable combustion analyzers are acceptable. Proposed § 63.7540(a)(10)(v) requires measurement of the CO & O2 concentration in the effluent stream. 75 FR 32059. EPA should specify it is permissible to use a portable electrochemical analyzer that meets EPA Method CTM-034. This will measure CO, O2, & NOx from stationary combustion sources. This would be a less expensive method of determining the CO concentration than having to hire a testing contractor and many facilities already utilize portable analyzers.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Comment: Proposed 63.7515(e) requires that annual tune-ups be performed between 10 and 12 months after the previous tune-up. This means the tune-ups will be more frequent than annual, a fact not reflected in the record, and will make compliance difficult, because a source will not necessarily be able to do the tune-up at the same time each year. For instance, if a tune-up is done in May one year, it must be done in April or May of the following year. Since good practice requires some allowance for problems and possible delay due to process operation issues, prudent sources will perform the tune-up in April. Then the next year‘s tune-up would be in March, etc. Under the proposed system, the work practice is actually required more frequently than annually, a fact not reflected in the record or cost analyses. We suggest 63.7515 be revised to specify annual tune-ups may be done at any time in the same calendar quarter as the initial tune-up was done, regardless of the particular month in which the tune-up occurred. If a boiler or process heater does not operate during the quarter, the tune-up should be required within 30 days after restart.

Recommendation: Revise the tune-up frequency language so tune-ups may be done in the same calendar quarter as the initial performance test in years when they are due. Add provisions for boilers and process heaters that are out-of-service during the quarter they are due for tune-up.

Response: The final rule clarifies the tune-up requirements and provides additional flexibility in scheduling the tune-up. Each annual tune-up specified in §63.7540(a)(10) must be no more than 13 months after the previous tune-up. Each biennial tune-up specified in §63.7540(a)(11) must be conducted no more than 25 months after the previous tune-up.
EPA agrees that a unit that is not operating should not be started up for the express purpose of conducting a tuneup. To ensure that tune-ups are as effective as possible and do not result in excess emissions, for units that are not operating on the required date for a tune-up, the tune-up must be conducted within one week of startup.

Comment: Tune-up Scheduling Should Be Amended.
EPA has proposed that units conduct tune-ups between 10 to 12 months following completion of the previous tune-up. This essentially requires tune-ups to be conducted more frequently then on an annual basis. This is unreasonable as it does not incorporate the requisite flexibility for units. Allowing this flexibility is especially important for process heaters that run for extended periods (i.e. 2 to 5 years) so that internal inspections cannot be done annually.

CIBO supports amending the Proposed Rule so that tune-up frequencies are relaxed to once every 5 years for units smaller than 10 MMBtu/hr and to biennially for units over 10 MMBtu/hr. One problem with requiring annual tune-ups is that this requirement is likely to interfere with scheduled maintenance outages and force a shutdown earlier than otherwise needed. Also, some units are not used continuously and the requirement should be changed to require these tune-ups after so many operating hours, rather than so much elapsed time. EPA could modify the Proposed Rule to allow tune-ups to be done in conjunction with normal inspections and/or overhaul schedules. In order to determine applicability, EPA could require unit specific demonstration of extended operating times. If a unit is not operated for a period of time, EPA should provide that tune-ups be relative to elapsed operating time.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2874.1, excerpt 6 for a response to tune-up frequency. Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Comment: Tune-ups Should Not Require Outside Certification of Adjustments.
Tune-up is defined in the Proposed Rule as "adjustments made to a boiler in accordance with procedures supplied by the manufacturer (or an approved specialist) to optimize the combustion efficiency." 75 FR 32065 (emphasis added). This definition limits the ability of an owner/operator to make adjustments to those that are done in accordance with procedures supplied by manufacturers or approved specialists. EPA should revise this to allow the owner/operator to establish and conduct appropriate procedures independent of this outside certification process. Many facilities have in-house specialists who are well-qualified to conduct optimization adjustments on units. In fact, in-house specialists have site specific information compared to the generic, and possibly in appropriate recommendations a manufacturer might provide. Many adjustments are not directly applicable to some units, particularly some process heaters. Therefore, all steps included in 63.7540(a)(10) should be qualified to only be used when appropriate for specific units. Generic procedures recommended by manufacturers and "approved specialists" will not always result in the appropriate adjustments and EPA should recognize and allow use of the knowledgeable resources currently available in-house at many facilities and companies.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups.

Comment: Because there will be many tune-ups at a typical major source, provision is needed to allow sources to move the tune-ups to other quarters, with agreement of the permitting authority. Tune-up personnel, site personnel and local Agency resources are limited and workload needs to be spread throughout the year to allow these resources to be efficiently utilized. In fact, for the same reasons, we would recommend sources be allowed to spread the initial tune-ups out over the year after the rule effective date rather than the 180 days provided.

Recommendations: Allow for changing tune-up timing to allow sources to spread out the effort throughout a year.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 81 for a response to scheduling of tune-ups.

Comment: Tune-ups are Inapplicable For Some Units.
As currently proposed, EPA's tune-up requirements are unworkable for certain units to which they apply. EPA should amend the work practice standards to reflect these discrepancies. Specifically, the tune-up procedures require owners and operators to inspect "the system controlling the air-to-fuel ration, and ensure that it is correctly calibrated and functioning properly." 75 FR 32014. This requirement is simply inapplicable to units that utilize metered fuel-air control systems with continuous excess air (O2) control where combustion is optimized continuously. On these units, EPA should recognize that system inspections, equipment calibrations, and operational checks are sufficient to ensure the system is "calibrated and functioning properly." Flexibility is what is needed, and EPA should incorporate in the tune-up requirements room for sources to utilize or modify procedures as applicable for and as needed to optimize specific units based on their design and operation.

Response: EPA agrees with the commenter and has changed some of the language regarding tune-ups to increase the flexibility of the requirements. Regarding the specific comment, units that continuously optimize the air-to-fuel ratio would satisfy the language, even as proposed, through a system inspection, equipment calibration, and operational check (as suggested by the commenter as an appropriate method of meeting the requirement).

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 282

Comment: It appears that EPA attempted to estimate the cost impact of the tune-up requirement using very limited information, which was extrapolated to the entire population of units affected by the BPH NESHAP. A survey of several of companies involved in tune-ups and studies revealed that tune-up costs are highly variable dependent upon unit-specific consideration. Based on refined cost information developed from our independent research indicating that EPA underestimated "per facility costs", as well as apparent inappropriate assumptions regarding the complexity of certain industry categories, we believe that it is likely that EPA has significantly underestimated costs for Gas 1 annual tune-ups. API's total estimated cost for tune-ups for the Gas 1 subcategory is approximately $24 million; however, because EPA did not provide a detailed breakout of tune-up costs for the Gas 1 subcategory, we are unable to provide further specific comment on the methodology or approach used to derive this estimate.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 71 for a response to underestimated tune-up costs.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)

Comment Excerpt Number: 307

Comment: Tune-up costs will vary substantially based on a number of factors including but not limited to the following: source type, design, number of burners, capacity, fuel type, and age of the source. Tune up costs are generally estimated by companies using an estimate of man-hours required to complete the work considering the cost per hour or day for qualified personnel. Additional costs a facility will incur will include on-site personnel time allotted to coordinate on-site contractors as well as administrative costs for the preparation and maintenance of the proposed annual tune-up report. Highly specialized fuel burning equipment will require more experienced personnel or contractors, which also impact costs. Although very small units may take as little as one day to complete a tune-up, larger more complex sources can require a two or three man team, which can span more than three weeks for an initial tune-up and up to two weeks for an annual tune-up. This could result in tune-up costs up to $36,000 for an initial tune-up and up to $12,000 for the annual tune-up depending upon the number of burners (30 to 50 burners may be present), as well as the size and configuration of the combustion system.
It should be noted that in EPA's assessment that it is assumed that all burners are accessible for inspection and that there are no costs associated with BPH shutdowns to allow inspection. Due to the site-specific nature of these impacts, Trinity was also unable to readily develop cost impacts estimates; however, such cost impacts would likely be significant.

Response: EPA thanks the commenter for communicating the results of the survey of contractors specializing in tune ups. In its final cost analysis EPA estimated the purchased technical cost of the tune-up using available technical literature prepared by the Industrial Extension Service USI boiler Efficiency Program. It is unknown what fraction of units would need to install replacement burner components as a result of the findings of the tune-up and so EPA did not estimate those costs. EPA also included in its ICR burden estimate time for the facility to submit and prepare records and the annual or biennial tune-up report, although these costs are not included in the purchase price of the tune-up. Further, many other commenters indicate that affected facilities are already conducing routine tune-ups, and presumably these units would be replacing broken components identified during the tune-up in order to maintain efficient combustion. Since many facilities are already undergoing the cost of routine tune-up preparation and implementation and will not experience significant additional costs to complete the same activity now required under the final rule, EPA disagrees that it has underestimated the costs of the tune-up.

Commenter Name: Matthew Todd and David Friedman

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1

Comment: This section presents revised cost estimates for tune-ups of gas-fired boilers and process heaters. Costs for both the initial and annual boiler and process heater tune-ups were obtained from boiler service contractors without adding additional costs associated with facility personnel oversight of the boiler tune-up program. The estimates also do not consider the added cost for replacing burner components.

The revised costs included in this section of the report are based on a survey of the following resources:
* Alstom Power, Monroeville, PA
* B & W Inc, Hummelstown, PA
* Corval Group, Atwater, MN
* Delval, Washington PA
* Devco Process Heaters, Tulsa OK
* Energy Control, Broadview Heights, OH
* Exotherm Process heaters, Houston, TX
* Kasco Boiler Repair Golden, CO
* North Carolina State University, Mechanical & Aerospace Engineering, Industrial Extension Service
* Servco Industrial Equipment, Salt Lake City, UT
* Tate Engineering, Baltimore, MD
* The G. C. Broach Company, Tulsa, OK

Based on feedback from a survey of a number of contractors specializing in tune ups, costs are generally dependent upon the heat input capacity of the combustion system. Accordingly, Trinity estimated total costs by multiplying vendor-estimated costs for certain heat input capacities by the population of units estimated by EPA in that category. In order to maintain consistency with EPA's calculations, the costs for the initial tune-up have been annualized over a 5 year period at 7% interest. Table 7-1 and Table 7-2 show annual costs estimated for Gas 1 and Gas 2 subcategories, respectively.

[See submittal for TABLE 7-1. ANNUAL COSTS FOR GAS 1 UNIT TUNE-UPS ($)]

[See submittal for TABLE 7-2. ANNUAL COSTS FOR GAS 2 UNIT TUNE-UPS ($)]

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 307 for a response to tune-ups cost estimates.

Comment: While we agree and support EPA's assessment of the Gas 1 subcategory and support the proposed work practices, we do have concerns with having a requirement to conduct annual boiler tune-up. We have natural gas-fired units that do not run frequently as they are ancillary or backup equipment, but do not contain any limitations on use in the event the "primary" unit is down for maintenance or repairs. When facilities have this redundancy, these ancillary units may only run for a limited number of hours during a calendar year. Having to conduct an annual tune-up on a boiler that may not have run during the past year or may have run for only a limited number of hours is not the best use of financial and technical resources. In order to minimize financial impact of the rule to facilities and to free-up limited technical boiler resources, we are suggesting EPA adopt an hours of operation interpretation rather than an annual requirement for these ancillary units. Our suggestion is for EPA to establish a subcategory for Gas 1 ancillary units where these units need to conduct a tune-up every 4000 hours of operation or five years whichever comes first.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Document Control Number: EPA-HQ-OAR-2002-0058-2834.1
Comment Excerpt Number: 2

Comment: The proposed approach to regulating boilers in the "Gas 1" subcategory should be based on actual operational hours and not on an annual or biannual basis, depending on the size of the unit.

Instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels (the "Gas 1" subcategory), EPA proposes to adopt work practices requiring an annual tune up of boilers with heat input capacity of greater than 10 million BTU per hour and a biannual tune up of boilers with heat input capacity of less than 10 million BTU per hour. Tuning a boiler based on a random time frequency without regard to actual operating hours serves no logical purpose. The frequency of boiler tuning should be based on operational hours. Potential to Emit (PTE) analysis are based on 8760 hours of operation, which is the equivalent of operating for 24 hours a day, seven days a week and 52 weeks a year. Denison University's gas boilers only operate a few weeks a year or less. Since PTE analysis are used as a basis for State Implementation Plans, and Title V Permitting, it would be logical to use 8760 hours of operation as a frequency for burner tuning, of boilers with heat input capacity of greater than 10 million BTU per hour. Burner tuning of boilers with heat input capacity of less than 10 million BTU per hour at a major source facility would be quite expensive for numerous small boilers. The use of 8760 hours of operation fits in the regulatory framework already put in place by USEPA.

EPA proposes that work practice standards are appropriate and justified for units in the Gas 1 subcategory out of concern for the cost of complying with numeric emissions limitations and based on the adverse policy incentives that would be created. The proposed work practices should be based on 8760 operating hours, for boilers having heat input capacity greater than 10 million BTU per hour. For boilers with heat input capacity of less than 10 million BTU per hour, the cost of burner tuning does not justify the expense and resulting environmental benefit.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Comment Excerpt Number: 3

Comment: Proposed requirements of the Work Practice Standard (Subpart DDDDD, Table 3, 75 FR 32068) should be modified in recognition of standard industry practice regarding scheduled maintenance turn-arounds, state-specific boiler inspection requirements, and safety concerns.

KNC operates boilers and process heaters in chemical manufacturing processes that can have periods of operation that extend for several years. On a regular basis and consistent with process safety regulations, standards, and good operating practices, these units are inspected and any required preventative maintenance is performed during a scheduled turn-around at the end of the extended operating period. The proposed annual tune-up requirement would result in a facility taking a boiler or process heater, along with the associated production unit, out of service in order to complete the annual tune-up. The additional startups and shutdowns could result in increased emissions from the facility, decreased energy efficiency, and increased worker safety concerns. In order to avoid these unintended consequences, KNC proposes the following modification to 63.7540(a)(10):

If you boiler or process heater is in either the Gas 1 (NG/RG) or Metal Process Furnace subcategories and has a heat input capacity of 10 million Btu per hour or greater, you must conduct a tune-up of the boiler or process heater in each calendar year in which the unit operates, or at the next scheduled maintenance turn-around, to demonstrate continuous compliance as specified in paragraphs (a)(10)(i) through (a)(10)(vi) of this section.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Commenter Name: Robert P. Strieter
Commenter Affiliation: The Aluminum Association
Document Control Number: EPA-HQ-OAR-2002-0058-2711.1
Comment Excerpt Number: 5

Comment: The proposed rule specifies Work Practice Requirements for the Metal Process Furnace subcategory. The Aluminum Association supports Work Practices for insuring emissions performance through proper burner maintenance (i.e., burner tune-ups). However, we disagree with the proposed rule requirement to install a natural gas meter on each furnace [§63.7540(a)(10)(vi)(C). Installation of natural gas meters will provide no useful information regarding burner performance because Metal Process Furnaces operate differently (cycle length, temperature and number) in any given 12-month period. Gas usage over 12 months is therefore not directly related to burner emissions performance or tune-ups. EPA should delete this requirement from the proposed rule.

Response: EPA has modified the final rule requirements to minimize the requirements for new individual gas meters at small units. In the final rule, units sharing a common fuel meter can use a common fuel meter to meet the requirement for measuring fuel consumption.

Comment: EPA should provide additional flexibility and/or alternatives to the proposed tune-up requirements. EPA should allow the option for operator-defined procedures rather than sole reliance on manufacturer's specifications.
EPA should provide clarification that CO measurements for tune-ups are not related to any CO emission standard in the rule.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 14

Comment: MidAmerican Questions the Need for Work Practice Standards for Units with Capacity under 10 million Btu Per Hour. MidAmerican submits that it is both unnecessary and impractical for the EPA to require Work Practice Standards for small boilers and process heaters (under 10 million Btu per hour). MidAmerican and all regulated entities with these smaller units have an economic incentive to guarantee optimal performance. Optimal performance will result in lower fuel input costs. The EPA does not need to prescribe the frequency of regular tune ups for these units. Further, to the extent that redundant, backup, and/or emergency equipment is not utilized, requiring annual tune-ups imposes significant and unnecessary costs.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 70 for a response to the tune-up exemption for small capacity units.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 15

Comment: Further, for many smaller units physical or operational adjustments of the burner cannot be performed. As one example, line heaters, once set up per the manufacturer's specifications and performance tested by the manufacturer, are maintenance free. These units have several alarms; if the operating temperature drops below the set point, the unit will shut down. However, there are no adjustments that can be made to these heaters. There is a very narrow operating range for many of these small boilers/process heaters. Field experience by MidAmerican technicians has demonstrated that adjustments to the air/fuel ratio for small heaters (less than 1 mmBtu/hour) are operationally difficult to make and such minor adjustments have caused the burners to fail to stay lit.

Response: In order to avoid finalizing requirements that cannot practically be met, EPA has adjusted the language to indicate “as applicable” for many of the tune-up requirements.

Comment: EPA’s Requirement for an Annual Tune-Up is Inconsistent With the Operational Practices of Some Industrial Boilers
In the Continuous Compliance Requirements of 63.7540, EPA proposes to require that certain source categories perform an annual tune-up. EPA should recognize that some sources

are routinely operated continuously for long periods at a time and do not schedule a yearly routine maintenance outage. Since conducting a tune-up requires inspection and maintenance of internal components, the unit must be shut-down. An annual tune-up in some cases would therefore force the shutdown of a unit at a potentially significant economic loss to the owner. To prevent this situation, EPA should allow a source the ability to seek a waiver or extension from the local permitting agency to allow sources to perform a tune-up on a less frequent basis that fits with the source’s operations.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Commenter Name: Cathy S. Woollums
Commenter Affiliation: MidAmerican Energy Holdings Company
Document Control Number: EPA-HQ-OAR-2002-0058-2786.1
Comment Excerpt Number: 16

Comment: MidAmerican also questions the proposed Work Practice Standard to measure fuel consumption. This requirement would be costly since most of these smaller units do not currently have a dedicated fuel gauge/meter. It is estimated that the labor and capital to install a meter would be about $5,000 per unit. Measurement of fuel consumption will not lead to lower emissions; there are numerous other variables that impact efficiency and, resultingly, emissions. If the fuel consumption increases or decreases, the temperature will stray and the unit will automatically shut down. Since the typical HAP emission from a heater of this size is less than 1 pound per year, the capital expenditure associated with fuel consumption is excessive compared to any real HAP emission reductions.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2711.1, excerpt 5 for a response to handheld instruments.

Commenter Name: Russ A. Wozniak
Commenter Affiliation: Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 44

Comment: Changes are Needed to the Annual Tune Up Requirements for Boilers and Process Heaters. The proposed requirements in 63.7515(e) to conduct annual performance tune-ups must not be stipulated in the rule. All boilers and process heaters undergo maintenance and preventive maintenance procedures as recommended by the manufacturers or by industry practice. Some of these units may not require annual tune-ups, and conducting annual tune-ups may not increase the performance of these units due to design and operating conditions. In addition, some tune-ups may require shutdowns and many units operate continuously for years before they are shutdown for scheduled maintenance.

In addition, some boiler preventative maintenance is coordinated with state inspections. Frequency of state inspections varies by state but can be 12 to 24 months. In these instances the rule must allow tune-ups to be coordinated with state inspections.

Therefore, the rule should be revised to require each affected unit to have a written tune- up schedule based on the manufacturer’s recommendation or industry practice and conduct tune-ups according to the written schedule.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 45

Comment: The proposed work practice requirements in 63.7540(a)(10) where measurement of CO concentration in the effluent stream before and after tune-up adjustments are made is excessive and should be deleted from the rule. There is no reason to require CO measurements where there are no CO emission standards to meet. This requirement may force facilities to conduct stack testing or CO measurements with no environmental benefit at considerable costs and effort. Due to these reasons, at a minimum, the CO measurement requirement must be deleted from the rule.

Response: EPA disagrees. The CO measurements can be done with handheld monitors that should add little expense to a tune-up program.

Commenter Name: Jerry Osheka
Commenter Affiliation: PPG Industries
Document Control Number: EPA-HQ-OAR-2002-0058-2938.1
Comment Excerpt Number: 1

Comment: PPG Supports the Inclusion of Work Practices as the MACT Floor for Gas 1 Fuels. Instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels (the "Gas 1" subcategory), EPA proposes to adopt work practices requiring an annual tune up of the boiler.

PPG strongly supports EPA's proposal to establish annual tune-ups as the MACT standard for existing and new Gas 1 boilers and process heaters, and respectfully urges EPA to adopt that proposal in final form, rejecting any comments urging the adoption of numerical emission limits, such as those on which EPA solicited comment. In adopting annual tune-ups as MACT, EPA should recognize expressly that they constitute the floor for existing and new Gas 1 boilers and process heaters and that no beyond-the-floor requirement would be appropriate for the reasons EPA gave in support of its proposal, namely: the exorbitant cost of compliance and the perverse incentives.

Response: In the final rule EPA is retained the tune-up quiring a work practice standard for the gas 1 subcategory. See the preamble for justification of the work practice standards and the classes of boilers and process heaters that are eligible for the tune-up in the final rule.

Commenter Name: Floyd DesChamps
Commenter Affiliation: Alliance to Save Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2921.1
Comment Excerpt Number: 1

Comment: We support inclusion of a biennial boiler tune-up requirement in the rule for applicable small (less than 10 million Btu input per hour) boilers as a means to enhance combustion efficiency and reduce HAP emissions. We suggest clarification as to whether the proposed rule would require tune-up solely of the combustion systems of boilers or of the entire boiler (or furnace) system (e.g., feedwater system, instruments, draft fan). We recommend the broader form of tune-up, which would allow additional efficiency measures to be addressed beyond combustion control.

Response: We appreciate the support of the biennial tune-up requirement. The final rule clarifies the requirements for the tune-up see §63.7540(a)(10). It should be noted that existing facilities are also subject to an energy assessment which is more comprehensive.

Commenter Name: Tom Brotherman
Commenter Affiliation: CPS Energy
Document Control Number: EPA-HQ-OAR-2002-0058-3138
Comment Excerpt Number: 2

Comment: We believe the work practice standards are a good idea. However, because of the low amount of hours per year our process heaters operate, we would like to see annual tune-up and testing be changed from an annual basis to a minimum/maximum amount of hours and/or maximum elapsed time. We are suggesting that the tune-1 and emissions testing be required between 7,300 and 8,760 operating hours or before the 5’ anniversary of the previous tune-up.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Commenter Name: Frederick R. Albrecht
Commenter Affiliation: SCA Tissue
Document Control Number: EPA-HQ-OAR-2002-0058-2843.1
Comment Excerpt Number: 2

Comment: In the area of Work Practices, the EPA rules are focused on CO reduction. SCA is focused on CO_2 reduction and has aggressive targets for this across the US and across our global operations. However, the EPA’s strong focus on reduction of CO emissions could have the unintended impact of increasing manufacturers’ emissions of other pollutants. For instance, a business could reduce its CO emissions by increasing its emissions of NOx. Clearly this would not be a desired outcome nor the intent of the EPA’s rule.
We recommend that the rules be modified to read: ‘Minimize total emissions of CO consistent with the manufacturer’s specifications while also assuring compliance with total emissions of other regulated pollutants."

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Commenter Name: Gregory A. Wilkins
Commenter Affiliation: Marathon Petroleum Company
Document Control Number: EPA-HQ-OAR-2002-0058-3119.1
Comment Excerpt Number: 3

Comment: Because EPA's current proposed approach has the unintended consequence of requiring inefficient operation of fired equipment (resulting in more fuel consumed than is optimal) Marathon recommends that the CO standards be adjusted so that equipment can be operated for optimal energy efficiency during all period of normal operation, including turndown. While optimal CO levels are generally no more than 400 ppmv, excess oxygen is added to assure safe operation of fired equipment to account for changes in process heat needs, fuel composition and other variables. HAP emissions are negligible with little change between these low CO levels and EPA's proposed standard. Finalizing more appropriate CO standards and work practices will result in less fuel consumption and fewer emissions.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: Clarify that Before and After Tune-up CO Measurement Does Not Require a formal "Performance Stack Test"
40 CFR 63.7540(a)(vi)(A) requires that concentrations of CO in the effluent stream be measured before and after the tune-up adjustments. We request EPA clarification that the measurement of CO before and after tune-ups is not considered a "performance test" and therefore the measurement does not have to be performed according to the test methods or procedures specified in Table 5 of the rule. This would allow us to use inexpensive handheld CO and humidity probes instead of having to hire a vendor to perform a stack test, while still providing adequate data for purposes of evaluating the effects of tune-up adjustments.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Commenter Name: William C. Herz
Commenter Affiliation: The Fertilizer Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2874.1
Comment Excerpt Number: 5

Comment: TFI is concerned about the feasibility of conducting annual tune-ups while operating process units. For most chemical facilities, inspecting the burner requires shutdown of the boiler itself and the associated chemical process unit. Required shutdowns result in emissions of pollutants above normal operating conditions. Shut downs also negatively impact plant efficiency as combustion of additional natural gas is required to shut down and restart the process unit. In cases where multiple burners are fired, pulling one burner while the others remain in service presents a significant safety hazard to the personnel pulling the burner.

TFI requests that the requirement for annual shut downs of chemical facilities for tune-ups be removed, given that it may decrease energy efficiency, increase environmental emissions, and increase worker safety risks. This is counter to the intent of the Major Source Boiler rule.
The environmental performance of the boiler can be detected by other inherently safer means. For natural gas fired sources, visual inspection of the flame pattern combined with CO and O2 concentration measurements are safer, non-intrusive indicators of burner performance.
TFI recommends that burner performance be evaluated while the reformer is operating. Requiring removal of the burner for inspection and cleaning is more prudent when conditions dictate, i.e. poor burner performance is detected due to poor flame patterns and overall CO concentrations.

Response: EPA has adjusted several provisions of the tune-up in the final rule in order to accommodate operational flexibilities. As long as owners/operators complete the parts of the tune-up that can be completed, they can postpone impractical requirements until the next scheduled outage.

Commenter Name: William C. Herz
Commenter Affiliation: The Fertilizer Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2874.1
Comment Excerpt Number: 6

Comment: All ASME Section 1 boilers are required to be inspected within five years from the date of the last inspection. This boiler inspection interval is consistent with preventive maintenance inspections of other equipment and catalyst life in a process unit. Requiring the full work practice standard within the same time interval as the ASME Section 1 boiler inspection would provide a more efficient and safe alternative while not sacrificing targeted emission limits.

TFI requests that EPA specify tune-up frequencies based upon standard industry practice regarding scheduled turn-arounds or a frequency consistent with state-specific boiler inspection requirements, such as the five-year interval for ASME Section 1 boilers. Other less intrusive portions of the requirements (e.g., inspecting air-to-fuel ratio, adjusting flame patterns, other manufacturer requirements) are already performed on an as-needed basis, and should be required to be recorded as completed rather than forcing an annual shut down of a process unit.

Response: We have not adjusted the tune-up frequency in the final rule. The commenter did not provide sufficient justification that tune-ups conducted less frequently will have the same impact on emissions as the schedule contained in the final rule. Further, technical literature provided by a Sustainable Energy Authority in Ireland provide graphs relating the time lapse since a previous tune-up with incremental improvement in fuel efficiency. In the final rule we have allowed limited exceptions to the biennial/annual frequency for units that supply process heat or steam to long term processes. These exceptions allow units to delay the more intrusive portions of the tune-up until the next scheduled shutdown. See preamble for justification of the work practice standards retained in the final rule.

Commenter Name: William C. Herz
Commenter Affiliation: The Fertilizer Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2874.1
Comment Excerpt Number: 7

Comment: For an ammonia plant reformer which may incorporate over one hundred burners in the same furnace, inspection of the burner performance is essential to ensure proper heat distribution in the catalyst tubes. Slight adjustments are frequently made not only to ensure cleanliness of the burner gun but also to correct the direction of firing based on heat distribution to surrounding tubes. Failure to perform these inspections can lead to failure of a catalyst tube, safety risk of tube rupture in the furnace, extended down time required for repair, and economic penalty caused from the loss production and combustion of natural gas during shut down and start up.

TFI requests that EPA exempt ammonia plant reformers from the requirement to remove and inspect burners since standard industry practice is to inspect burners for proper performance to prevent catastrophic failure of catalyst tubes during normal operation. Other less intrusive portions of the requirements (e.g., inspecting air-to-fuel ratio, adjusting flame patters, other manufacturer requirements) are already performed on an as-needed basis, and should berequired to be recorded as completed rather than forcing removal of the many burners in an ammonia reformer.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2874.1, excerpt 5 for a response to tune-ups requirements for ammonia plants.

Commenter Name: Sarah E. Amick
Commenter Affiliation: Rubber Manufacturers Association
Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 7

Comment: Annual tune-ups intended to minimize CO emissions are proposed for existing boilers and process heaters with a design heat duty of >10 MMBTU/hr that fire Gas 1. Biennial tune-ups are required for units with a design heat input <10 MMBTU/hr regardless of what type of gas they combust. RMA does not believe that such tune-ups are MACT, as EPA claims in the proposal preamble.

The basis for EPA's conclusion that a tune-up for minimizing CO constitutes the MACT floor is the claim that many States require tune-ups. While this is correct to some extent, these State tune-ups typically are for the purpose of minimizing NOx or optimizing combustion by minimizing O2 and do not require minimizing CO as EPA proposes. In fact, reducing CO using the tune-up procedure EPA proposes would violate the very tune-up requirements EPA cites, because reducing CO increases NOx and requires increasing O2. Furthermore, it is not clear that the proposed tune-up would reduce any annual emissions, since the tune-up itself raises emissions while it is being done. Thus, while we believe a simple, non invasive inspection work practice might add some value and meet the requirements of §112, the proposal to use the tune-up to minimize CO emissions should not be finalized as presented.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Commenter Name: William O'Sullivan
Commenter Affiliation: New Jersey Department of Environmental Protection

Commenter Affiliation: National Association of Manufacturers
Document Control Number: EPA-HQ-OAR-2002-0058-2845.1
Comment Excerpt Number: 10

Comment: EPA should require only a one time tune-up for smaller boilers and process heaters.

Manufacturers recommends that EPA require only a one time tune-up for smaller boilers and process heaters with rated heat input less than 2 million British Thermal Units (BTUs). Currently, both the South Coast Air Quality Management District and Antelope Valley Air Quality Management District exempt boilers and process heaters with a rated heat input less than or equal to 2 million BTUs per hour from having their burners tuned. Because of the small size of these units, the cost burden of regular tune-ups far outweighs any environmental benefit that may be achieved.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 70 for a response to the tune-up exemption for small capacity units.

Commenter Name: Richard Krock
Commenter Affiliation: The Vinyl Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2944.1
Comment Excerpt Number: 12

Comment: Not all boilers and few process heaters can be readily shutdown. Inspection should be delayed until the unit can be shutdown without impact. For units such as process heaters that do not shut down for extended periods of time, scheduling flexibility must be provided so that tune-ups can be done in association with normal inspection and overhaul schedules. EPA should also reword the work practice requirements so that sources have flexibility to adapt procedures as applicable and appropriate for specific sources. In addition, the “tune-up” definition implies that use of an approved specialist could be required. EPA should recognize that many companies have in-house personnel who are already well qualified, and already perform adjustments to burner systems. Continued use of these in-house resources must be supported.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 12

Comment: Unscheduled Shutdowns. As proposed in section 63.7540(a)(10)(i)-(iii) for tune-up activities, it may be necessary to shut down a boiler or process heater to perform these inspections. However, most boilers and process heaters cannot be readily shut down to perform a burner inspection as required by (a)(10)(i) and (ii), since burners are not always retractable and cannot always be inspected or cleaned with the boiler or process heater in service. Furthermore, many boilers operate with positive firebox pressures that would expose personnel to hazardous conditions for on-line inspections. In those cases where the boiler or process heater is not spared or cannot be shut down without impacting steam or process heat consumers, this requirement should allow for delaying the burner inspection until the unit can be shut down without impact. Potential unit and process shutdowns were not considered in evaluating the tune-up emissions impacts, costs or burdens and are not justified.

Clarify that boiler and process heaters need not shut down to accomplish the required inspections or to clean burners, or allow the inspections to occur with planned maintenance downtimes of these sources.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to scheduling of tune-ups.

Commenter Name: Richard Rosvold

Document Control Number: EPA-HQ-OAR-2002-0058-2955.1
Comment Excerpt Number: 13

Comment: Annual/biennial tune ups are excessive, especially for liquid- and gas-fired boilers with low hours of operation. These units burn relatively cleanly and generally do not become "out of tune" this quickly. We suggest a tune up frequency of once every five years for units burning distillate oil, biodiesel, and gaseous fuels, or that the tune-up frequency be based on hours of operation of the unit.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Commenter Name: Edward E. Quick
Commenter Affiliation: Celanese International Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2840.1
Comment Excerpt Number: 21

Comment: Celanese agrees in general that work practice standards such as boiler inspections and tune-ups are appropriate for smaller boilers and those fired by natural gas. We disagree with the tune-up requirements to: "Minimize total emissions of CO consistent with the manufacturer's specifications; Measure the concentration in the effluent stream of CO in parts per million, by volume, dry basis (ppmvd), before and after the adjustments are made..."

Tuning boilers to reduce CO emissions often results in a trade off between CO and NOx emissions. In many cases, the lowest possible CO emission rate is achieved by increasing excess air and flame temperature. These conditions decrease boiler and process heater efficiency, and also increase emissions of other pollutants, such as NOx and greenhouse gases. We therefore recommend that these two requirements under the work practice standard be removed from the final regulation.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment Excerpt Number: 49

Comment: Proposed Rule Language §63.7540(a)(10)(v):
"Measure the concentration in the effluent stream of CO in parts per million, by volume, dry basis (ppmvd), before and after the adjustments are made; and."
Comments:
Section §63.7540(a)(10)(v) indicates that the CO concentration in the effluent stream must be measured before and after the required adjustments are made. However, Section 63.7540 does not specify the method or equipment required to take this measurement. This section should be revised to clarify to include the required measurement methodology and equipment. A handheld portable equipment should be sufficient to conduct tune-up adjustments.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Commenter Name: Traylor Champion
Commenter Affiliation: Georgia-Pacific LLC

Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 65

Comment: Boiler tune up procedures for natural gas boilers would require CO testing to measure the effectiveness of the tune up. However the proposed rule does not specify the procedures that must be used for this test. CO measurements for the tune up need not be conducted with the rigor of EPA Method 10 or 10A since the results are not used for compliance demonstration – only as an indication of a process improvement. There are several hand-held CO monitors that can be accurately and effectively used for this purpose by plant personnel instead of hiring an outside testing contractor.
GP urges EPA to clarify in the final rule that CO testing during an energy audit does not need to be done by EPA stack testing methods, but can be performed using commercially available portable CO analyzers.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3137.1, excerpt 36 for a response to handheld instruments.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 199

Comment: EPA SHOULD REVISE THE TUNE-UP REQUIREMENTS. Proposed section 63.7540(a)(10) contains the specific tune-up work practice requirements for existing boilers and process heaters. We have the following comments on the specifics of the proposed tune-up work practice. ACC believes proposed section 63.7540(a)(10)(i)-(iii) reflect typical tune-up activities. Many jurisdictions require annual boiler inspections for safety reasons and boilers are often spared or can be shutdown when weather conditions are mild. Some jurisdictions require such inspections for process heaters, particularly as part of a NOx minimization effort.

However, not all boilers and few process heaters can be readily shutdown. The proposed (a)(10)(i) and (ii) burner inspections could require such a shutdown, since burners are not always retractable and cannot always be inspected or cleaned with the process heater in service. In those cases where the boiler or process heater is not spared or cannot be shutdown without impacting steam or process heat consumers this requirement should allow for delaying the burner inspection until the unit can be shutdown without impact. Potential unit and process shutdowns were not considered in evaluating the tune-up emissions impacts, costs or burdens and are not justified. EPA should clarify that boiler and process heaters need not shutdown to accomplish the required inspections or to clean burners. For units such as process heaters that do not shut down for extended periods of time, scheduling flexibility must be provided so that tune-ups can be done in association with normal inspection/overhaul schedules. For example, in the Mandatory Reporting Rule for GHG Emissions, EPA allows for postponing initial or subsequent calibrations until the next scheduled maintenance outage. [40 CFR 98.3(i)(6), 74 Fed. Reg. at 56381.] A similar approach should be used in the Boiler rule for scheduling of tune-ups on equipment which does not lend itself to an annual frequency.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 112 for a response to tune-up requirements.

Comment: Proposed section 63.7540(a)(10)(iii) requires "Inspect the system controlling the air-to-fuel ratio, and ensure that it is correctly calibrated and functioning properly." This wording presumes an automatic air-to-fuel ratio controller, but those are present on a minority of process heaters. Where metered fuel/air control systems with O2 trim is installed, there is no real need for periodic "tune-ups" since combustion is continually optimized. Rather, burner/combustion system inspections, control equipment calibrations, and operational checks are all that should be needed to verify proper operation. EPA should reword the work practice requirements so that sources have flexibility to adapt procedures as most applicable and appropriate for specific sources.

Many units only have automatic draft control and individual, manual burner air control. For smaller units, draft control may be manual. Adding automatic air-to-fuel controls, as this requirement might be interpreted to require, is a very large, unjustified cost for units that do not have it, because it requires adding a forced draft combustion air system and perhaps an induced draft system. No such step was considered in the record and it is not justified.

EPA should reword proposed section 63.7540(a)(10)(iii) as follows:

"Inspect the draft control and burner air control systems to ensure they are operating properly. Inspect the system controlling the air-to-fuel ratio, if any, and ensure that it is correctly calibrated and functioning properly."

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 113 for a response to flexibility with respect to an air-to-fuel ratio controller.

Comment: Proposed section 63.7540(a)(10)(iv) and (v) are not typical tune-up requirements for either boilers or process heaters and do not reflect MACT. State tune-up requirements require minimization of NOx, not CO. Thus, these subparagraphs do not reflect the state requirements and would violate the State tune-up requirements for minimizing NOx. Additionally, the tune-up requirement conflicts with the proposed energy assessment work practice requirements, because tuning a boiler or process heater for minimum CO generally requires increasing excess air, which increases energy consumption, in direct conflict with the energy assessment directive to decrease energy consumption.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment Excerpt Number: 202

Comment: If the draft control on a boiler or process heater is working properly, as (a)(10)(iii) confirms, and there are no mechanical problems with the flame pattern, as (a)(10)(ii) confirms, there is no justification for measuring CO, since CO will be very low when these items are operating properly. Furthermore, these are elements typically checked and corrected if CO were high. Additionally, the mass of POM emissions that might be reduced from a gas fired boiler or process heater is insignificant.

EPA should remove the CO measurement requirements in the final rule. If they are not removed they must be justified, considering the NOx emissions increase they will engender and the rule must specifically address state requirements to minimize NOx. The O2 level in a boiler or process heater also must consider draft limitations, flame impingement, and flame stability to assure a safe, reliable and efficient operation, and these conditions are not recognized in the EPA tune-up procedure.

Response: EPA disagrees with the commenter. The requirement in the final rule is to optimize CO, rather than minimize, and the optimization can consider NOx.

Commenter Name: Jim Griffin

Comment: If burner/control adjustment relative to CO emissions is maintained in the tune-up procedure, the following changes are needed to reflect EPA’s description of this work practice, the Agency cost and burden estimate, to make the CO adjustment practical, and not to have it result in increased NOx and other emissions.

EPA should clarify the regulatory language that CO is only to be minimized to the extent the adjustments do not increase NOx emissions, decrease unit combustion efficiency, cause flame impingement or flame instability, or cause other safety issues, and that portable CO and O2 analyzers are acceptable, and that these tests are not performance tests. Further, it should be made clear that the tuning is to be done at a single representative operating rate. Neither the rulemaking record nor combustion principles justify multipoint tune-ups, especially when some units basically operate at a fixed rate.

For a short term adjustment situation, unit firing and stack conditions will not change enough for the stack moisture to vary significantly. Comparing CO measurements on either a wet or dry basis, before and after adjustment, is more than adequate to reflect the impact of adjustments.

The oxygen measurement should be specified to be based on either an O2 CEMS reading, if the unit has one, or measurement using a portable emissions monitor. It should be made clear that a Method 3 oxygen measurement is not required.

EPA should not finalize proposed section 63.7540(a)(10)(iv) and (v). If these requirements are maintained, they should be simplified and clarified as discussed in items 1-3, above and EPA must specifically over-ride State tune-up requirements to minimize NOx and/or O2.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO. Comment: Proposed section 63.7515(e) requires that annual tune-ups be performed between 10 and 12 months after the previous tune-up. This means the tune-ups will be more frequent than on an annual basis, a fact not reflected in the record, and will make compliance difficult, because the source will not be able to do the tune-up at the same time each year. For instance if a tune-up is done in May one year, it must be done in April or May of the following year. Since good practice requires some allowance for problems and possible delay due to process operation issues, prudent sources will perform the tune-up in April. Then the next year's tune-up would be in March, etc. Under the proposed system, the work practice is actually required more frequently than annually, a fact not reflected in the record or cost analyses, and obviously not justified. We suggest section 63.7515 be revised to specify that annual tune-ups may be done at any time in the same calendar quarter as the initial tune-up was done, regardless of the particular month in which the tune-up occurred. If a boiler or process heater does not operate during the quarter, the tune-up should be required within 30 days after restart.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 81 for a response to scheduling of tune-ups.

Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 205

Comment: The definition of "Tune-up" in the proposed rule correctly stipulates "optimize the combustion efficiency, whereas language noted above in section 63.7540(a)(10) requires "minimize total emissions of CO," which as noted above is an incorrect approach to a tune-up and will lead to lower efficiency and higher net total emissions. As indicated above, EPA needs to correct the language in section 63.7540. In addition, the "tune-up" definition implies that use of an approved specialist could be required. EPA needs to recognize that many companies have in-house resources who are already well qualified, and already do perform adjustments to burner systems. Continued use of these resources must be supported.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-3213.1, excerpt 117 for a response the definition of a tune-up. Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 5 for a response to flexibility with respect to manufacturer's specifications and tune-ups.

Comment: EPA should also establish annual tune-up work practice as the MACT standard for biomass boilers. For example, in the forest products industry alone, the estimated cost of complying with the proposed HAP emissions limitations for biomass boilers is $3.3 billion. This is an extraordinary cost that, in the context of the forest products industry, equals or exceeds the magnitude of the economic burden that EPA predicts for the Gas 1 subcategory. Similarly severe economic impacts are expected in other industry sectors where biomass boilers are widely use, such as the furniture, sugar, and agricultural products industries. Thus, there is strong economic justification for prescribing work practice standards for biomass boilers in lieu of numeric emissions limitations.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Comment: A work practice for certain gas-fired units is appropriate, but should apply to all gas units.
The numeric emissions limits for gas-fired units in the rule will result in technically/practically infeasible standards and, from an energy efficiency standpoint, increased emissions by requiring non-optimal operating conditions. Natural gas, refinery fuel gas, and petrochemical fuel gas, often integrated in refinery fuel systems, have comparable composition and emission profiles and should be considered Gas 1 sources. .

Response: EPA has determined that to the extent that process gases are comparable to natural gas and refinery gas, combustion of those gases in boilers and process heaters should be subject to the same standards as combustion of natural gas and refinery gas. Therefore, we are providing a mechanism by which units that combust gaseous fuels other than natural gas and refinery gas can qualify as Gas 1 units and be subject to the standards for Gas 1 units.

EPA is providing a fuel specification that can be used by facilities to qualify Gas 2 units for the Gas 1 standards. The fuel specification would also allow facilities to perform precombustion gas cleanup in order to qualify Gas 2 units for the Gas 1 standards. For those process gases that do not meet the fuel specification and are not processed to meet the contaminant levels, we are finalizing emissions limits for Gas 2 units.

Comment: NHDES strongly supports adoption of timely final regulations in order to achieve the benefits to public health that will result from the regulations. In keeping with that desired outcome, we would recommend that EPA consider including provisions in the regulation that not only require effective emission limits for CO, but also a combustion efficiency component to ensure that combustion efficiency, and not just CO emission rates, be improved. NHDES would recommend that for existing units, EPA require annual tune-up and testing of combustion efficiency and for new units, EPA require that the manufacturer of the units certify that they meet efficiency standards along with an annual tune-up requirement.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: EPA should, however, take the necessary next step and extend the work practice approach toall gas-fired units. Despite the exceedingly strict emissions limits that are proposed, EPA has not identified a demonstrated path to compliance for the remaining gas-fired units for which EPA has not proposed to make work practices available. Rather than imposing undue and unrealistic costs and standards on these remaining gas-fired boilers, EPA should allow work practices rather than require emissions limitations.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2699.1, excerpt 1 for a response to work practices for all gas units.

Comment: The U.S. Department of Energy regulates the efficiency of small “package” boilers in 10 CFR Part 431. This statute sets the efficiency for oil-fired hot water boilers between 300,000 Btu/hr and 2.5 MMBtu/hr at 82% thermal efficiency as of March 2, 2012; hot water boilers greater than 2.5 MMBtu/hr must have 84% combustion efficiency as of March 2, 2012.

Oil-fired steam boilers must have a thermal efficiency of 81% for both size categories as of March 2, 2012. Such combustion efficiencies effectively limit emissions of CO and other pollutants. We recommend that EPA adopt similar efficiency standards for new and existing boilers with capacities between 1 and 10 MMBtu/hr, and that EPA require a one-time energy audit.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2960.1, excerpt 70 for a response to the tune-up exemption for small capacity units.

Comment: Include additional fuel oil burning flexibility in the final rule. Work practice standards are more appropriate for fuel oil burning at refinery locations and remote locations without access to natural gas. If EPA decides to proceed to set HAP emission limits on refinery oil units, the ten-percent allowance needs to be made on the collection of heaters and boilers subject to the standards instead of the individual pieces of equipment.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2863.1, excerpt 37 for a response to work practices for remote locations.

Comment: Work Practice Standards Should Apply to All Gas-Fired Units. In the IB MACT rule, EPA has proposed to require existing boilers and process heaters burning either natural gas or refinery gas to meet a work practice standard rather than an emission limit. The work practice standard would require these units to conduct an annual tune up. See 75 Fed. Reg. 32,025. This work practice standard should be extended to IB units burning coal-derived gas.

The electric utility industry is increasingly being asked to consider constructing integrated gas combined cycle ("IGCC") units. These units include a coal gasifier that produces gas for later combustion in a gas turbine. The gas from an IGCC unit is cleaned prior to combustion so in terms of trace HAPs it is little different than natural gas or refinery gas.

Some coal-gasification processes include an additional methanation step that results in the production of synthetic natural gas ("SNG"). This product is indistinguishable from natural gas. Indeed, it qualifies for transport in natural gas pipelines. The proposed distinction between natural gas and other gas sources (like SNG) creates a compliance dilemma for end users. How does a natural gas user know if the gas from the pipeline that supplies its plant contains some amount of synthetic natural gas?

EPA's Gas 1/Gas 2 distinction is unworkable and all gas-fired IBs should be subject to work practice standards. If EPA keeps the distinction between gas sources, then it should, at a minimum, add coal-derived gas to the fuels in the Gas 1 category.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2699.1, excerpt 1 for a response to work practices for all gas units.

Comment: Rationales similar to those that support the proposed approach for the Gas-1 subcategory apply well to biomass boilers. As an AF&PA analysis demonstrates, in the forest products industry alone the estimated cost of complying with the proposed HAP emissions limitations for biomass boilers is $3.3 billion. For the forest products industry this is a cost burden of at least the same magnitude as that EPA estimates for the Gas-1 subcategory, and this level of severe economic impact is expected in the many other industry sectors where biomass boilers are widely used. Biomass is a relatively "clean" fuel relative to coal and other fossil fuels. Biomass-fired boilers typically have far lower HCl and Hg emissions than a comparable, well-controlled coal-fired boiler.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 107

Comment: The rationale that supports the proposed approach for the Gas 1 subcategory applies equally well to biomass boilers and, therefore, provides ample support for adopting alternative approaches such as the health-based alternatives, work practices instead of numeric emissions limitations, and otherwise considerably improved, reasonably established emissions limitations for biomass boilers. For example, in the forest products industry alone, the estimated cost of complying with the proposed HAP emissions limitations for biomass boilers is $3.3 billion. This is an extraordinary cost that, in the context of the forest products industry, equals or exceeds the magnitude of the economic burden that EPA predicts for the Gas 1 subcategory. Similarly severe economic impacts are expected in other industry sectors where biomass boilers are widely use, such as the furniture, sugar, and agricultural products industries. Thus, there is strong economic justification for prescribing work practice standards for biomass boilers in lieu of numeric emissions limitations.

In addition, biomass is a "clean" fuel in many of the same respects as the Gas 1 fuels. For example, a biomass-fired boiler typically will have far lower HCl and mercury emissions than a comparable, well-controlled coal-fired boiler. Perhaps more importantly, biomass-fired boilers produce no net CO_2 emissions, which makes the combustion of biomass an important tool in managing and reducing the Nation's carbon footprint. Similarly, biomass is an abundant, renewable domestically-produced fuel that can help reduce reliance on foreign sources of fossil fuel and, thus, improve the Nation's energy security. Prescribing overly stringent HAP emissions limitations on biomass boilers will create a significant barrier to the continued use and expansion of biomass fuels and incentivize the use of less desirable fossil fuel alternatives.
In light of the inordinate costs of complying with the proposed HAP emissions limits for biomass boilers and the strong policy reasons for promoting the combustion of biomass, EPA has ample justification to prescribe work practices and other alternative approaches rather than overly stringent HAP emissions limitations for biomass boilers.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits. Refer to DCN EPA-HQ-OAR-2002-0058-2882.1, excerpt 7 for a response the cost impact to the forest products industry.

Comment: As stated in the Clean Air Act, "if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice, or operational standard, or combination thereof, which in the Administrator's judgment is consistent with the provisions of subsection (d) or (f) of this section. 42 U.S.C. § 7412(h). While the D.C. Circuit Court of Appeals has ruled that EPA cannot set floors of 'no control,' the court also affirmed EPA's authority under CAA § 112(h) to use work-practice standards instead of emission floors where "measuring emission levels is technologically or economically impracticable." Sierra Club v. EPA, 479 F. 3d 875, 884 (D.C. Cir. 2007). Given the limited and sporadic operation of emergency and backup boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should require work practices in lieu of emission limits.
In the recently promulgated CI RICE MACT, EPA set work practices including regularly scheduled maintenance and the cataloging of hours of operation to ensure compliance with relevant emission limits for emergency use engines. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 FR at 9655-56. As

stated by EPA, “EPA believes that work practices are appropriate and justified for this group of stationary engines because the application of measurement methodology is not practicable due to technological and economic limitations.” Id. at 9556. As further stated by EPA:

[U]sing these procedures would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.

Id. at 9661. Similarly, as stated in the memorandum entitled Existing Stationary Non-Emergency CI RICE Less Than 100 HP and Existing Stationary Emergency CI RICE Located at Major Sources and GACT for Existing Stationary CI RICE Located at Area Sources (February 15, 2010) cited in EPA’s final rule:

For existing stationary CI emergency engines located at major sources, EPA determined it is not feasible to prescribe or enforce an emission standard because the application of measurement methodology to this class of engine is impracticable due to the technological and economic limitations. Emergency engines typically only operate during emergencies or during periods of routine testing and maintenance. EPA determined that application of the emissions measurement methodologies during either of these periods is not practicable. It is impracticable to test emissions from stationary CI emergency engines during periods of routine testing and maintenance using the test procedures specified in the rule because it would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.

EPA also excluded black start units from HAP emission regulations in the CI RICE MACT rule. While these units operate whenever a turbine generator starts, and therefore are not limited to emergency operations, EPA nonetheless recognized the importance of exempting these units from numeric HAP standards, finding that “the short time of operation for these engines (10–15 minutes per start) makes application of measurement methodology for these engines using the required procedures, which require continuous hours of operation, impracticable. Requiring numerical emission standards for these engines would actually require substantially longer operation than would occur normally in use, leading to greater emissions and greater costs.” National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 FR at 9662.

It is worth noting that these exceptions were not created because the emissions generated have no impact on the environment. As EPA found, “[t]he majority of stationary CI engines are used for emergency purposes. EPA has estimated that 80 percent of stationary CI engines are emergency engines and EPA has taken steps in the final rule to reduce the burden on owners and operators of these engines.” National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 FR at 9658. Rather, the basis for promulgating work practices in lieu of emission standards is the impracticality of prescribing or enforcing an emission standard. See 42 U.S.C. § 7412(h).

Emergency, startup, and backup boilers, like emergency and black start CI RICE, are operated for only short periods of time and cannot feasibly be tested pursuant to EPA standards. Work practices should therefore also serve in lieu of emission monitoring and control technology for

emergency and backup boilers. For example, under 40 C.F.R. § 63.7545(d) of the Proposed Rule, a Notification of Intent must be submitted at least 30 days before any performance test. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 FR at 32006. As a result, even if a limited use boiler were operated for an entire month after an unplanned start, there would be no time to conduct the necessary performance tests. In addition, most test methods require steady state conditions that may not be achieved during limited use operations and, once a steady state has been reached, would require the boiler to continue operating at steady state for enough time to conduct the three 4-hour test runs required by the proposed rule for most compliance tests. See Proposed 40 CFR 63.7520(d). Even during regular operation, a limited use boiler would still need to operate for at least 12 hours in steady state condition in order to accommodate the variability attendant in these performance tests. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 FR at 32033 (stating that EPA selected a 12 hour averaging period for demonstrating continuous compliance "to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits").
1 75 Fed. Reg. at 32025. Similarly, EPA is proposing that boilers and process heaters with heat input capacities greater or equal to 100 MMBtu/hr "demonstrate that average CO emissions, on a 30-day rolling average, are at or below the proposed CO limit." National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 FR at 32034. This averaging period is essential to accommodating expected data variability, including SSM events. See, e.g. National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 FR at 5521. See Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 102 (rejecting a 24-hour averaging period because a 30-day rolling average "accounts for the variability in fuel characteristics (e.g., moisture, Btu content, mixture) that occur for solid fuel-fired boilers and process heaters"). Without the ability to test for 30 continuous days or thereabouts, a limited use boiler could not reasonably be expected to meet the same emission limits due to their reduced ability to accommodate data variability and operators cannot adequately determine compliance with numeric emission limits.
The result would be a marked inability to practically measure emissions without operating these units for significant periods of time for the sole purpose of conducting emissions testing. As with the recently regulated emergency CI RICE, this would result in a new increase in emissions through the very effort to control emissions from these units. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 FR at 9655-56. Work practices are therefore the most feasible control for limited use boilers and should be adopted in the new rule.

Instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels (the "Gas 1" subcategory), EPA proposes to adopt work practices requiring an annual tune up of the boiler. For units larger than 100 mmBtu/hr, EPA explains that "the capital costs estimated for installing controls on these boilers and process heaters to comply with MACT limits for the five HAP groups is over $14 billion."(75 Fed. Reg. at 32025) EPA further explains that:

[T]he need to employ the same emission control system as needed for the other fuel types would have the negative benefit of providing a disincentive for switching to gas as a control technique (and a pollution prevention technique) for boilers and process heaters in the other fuel subcategories. In addition, emission limits on gas-fired boilers and process heaters may have the negative benefit of providing an incentive for a facility to switch from gas (considered a “clean” fuel) to a “dirtier” but cheaper fuel (i.e., coal). It would be inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular, to adopt requirements that would result in an overall increase in HAP emissions.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2808.1, excerpt 16 for a response the request for work practices not emission limits for limited-use combustors.

Commenter Name: James Santory
Commenter Affiliation: Calgon Carbon Corp.
Document Control Number: EPA-HQ-OAR-2002-0058-2956.1
Comment Excerpt Number: 3

Comment: The regulatory approach to units in the "Gas 1" subcategory should also be applied to units in the "Gas 2" subcategory. Calgon Carbon supports that EPA’s conclusion that work practice standards are appropriate for units in the "Gas 1" subcategory in consideration of the substantial cost of compliance relative to the environmental benefit. We believe this same rationale is applicable to well-maintained units in the "Gas 2" subcategory. Calgon Carbon believes that in the majority of cases there is not a significant difference in the emissions profile of a well-maintained unit in the "Gas 2" subcategory as compared to a "Gas 1" unit. Therefore, Calgon Carbon believes the work practice standards proposed for "Gas 1" units should be similarly applied to "Gas 2" units, or alternatively, the distinction between "Gas 1" and "Gas 2" units should be removed. Work practice standards would result in significant environmental benefit, as recognized by EPA relative to "Gas 1" units, without the projected substantial economic impacts associated with the application of the proposed numeric standards on "Gas 2" units. Moreover, Calgon Carbon believes the application of work practice standards across both "Gas 1" and "Gas 2" units would encourage business and industry to continue to explore the utilization of energy sources in efficient and innovative ways.

Comment: Another option CIBO recommends is that in lieu of a set ppm limit for CO and using a CO CEMS to demonstrate continuous compliance, EPA should borrow from the work practice standard. However, instead of tuning to minimize CO, sources would tune to maximize efficiency of combustion over the load range typical of the boiler. The typical load range can be determined using historical plant data or even the load bin-type calculations used in the Part 75 regulations. To ensure continuous compliance with the source could use the CO CEMS to monitor the boiler tune by establishing a typical range of CO for the individual unit immediately after the tune-up.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2506.1, excerpt 13 for a response the consequences of minimizing CO.

Comment: Emission Limits for Natural Gas-Fired Boilers/Process Heaters are Not Feasible and EPA Should Extend the Gas 1 Work Practices Approach to the Gas 2 Subcategory.
As discussed above, CIBO agrees with EPA's proposed approach to institute work practices for new and existing units in the Gas 1 subcategory and in the Metal Process Furnace subcategory. Emission limits for units burning natural gas are not feasible given the challenges associated with testing units with such low HAP emissions. Such an approach also would be a significant policy shift from how EPA treated these sources in the earlier Boiler MACT promulgated in 2004 and how EPA has treated natural gas-fired units in other rules.

For example, when EPA made the finding under § 112(n)(1)(A) that the regulation of electric utility steam generating units (EGUs) under § 112 is appropriate and necessary, the agency specifically determined that natural gas-fired EGUs were not included in the listing because the HAP emissions from these units "were negligible based on the results of [EPA's utility Report to Congress]." In fact, in the section of EPA's notice of finding and listing of EGUs under section 112, EPA notes that "[c]onversion of coal- and oil-fired units to natural gas firing effectively eliminates HAP emissions." Furthermore, in the NESHAP for Stationary Combustion Turbines, Subpart YYYY, EPA does not impose emission limits on existing units from any of the subcategories, including natural gas-fired units. Finally, as noted earlier, in EPA's area source proposal for boilers, natural gas-fired units are excluded from that rule because they do not emit the HAPs of concern and they are not needed to meet the 90% HAP reduction requirement in the statute. As these examples demonstrate, setting emission limits for natural gas-fired units would be a significant departure from how EPA has treated this fuel under section 112 in other rules.

The discussion above explaining why work practices are justified for natural gas-fired boilers and process heaters also serves to demonstrate why the data in the database are not reliable for setting emission standards for this subcategory of units. Given the very low-HAP emissions from natural gas-fired units, testing of these units results in data that are below or close to the detection limits for EPA's test methods or beyond the quantification capability of these tests. Thus, the data in the database are not reliable and not reproducible because the data often times represents noise as opposed to actual emissions data.

Comment: D. EPA should extend the work practice approach used for Gas 1 to include

Distillate Oil fired units.
While CIBO supports work practice standards, EPA should extend the work practice standard to cover distillate oil-fired units (including No.1, 2, ultra low sulfur distillate and diesel fuel, jet fuel, and other similar oils). EPA has treated distillate oil very much like it treats gas in the Proposed Rule and it should take the same approach when it comes to a work practice standard versus emission standards.

EPA established the MACT floors for liquid-fired units based on fuels that have low sulfur, chloride, and mercury content. As a result, the MACT floors were based on fuel characteristics and not on consideration of emission controls employed by the units. Considering this, EPA should not impose controls on boilers that burn a clean liquid fuel such as distillate fuel that do not contain the low chloride and mercury contents of the fuels used to establish the MACT floors. This is unreasonable, as units that burn distillate fuels have no control over the quality of the oil they receive, and will have additional costs to control very low levels of Cl and Hg to the HCl and mercury limits. In many cases it is problematic to try to design and obtain emissions controls for such low contaminant levels, since the levels in the oils are below detection levels already.

If EPA determines that work practice standards are not appropriate for distillate oil, emission limits should be changed and based on fuel oil quality or composition. This would be an acceptable approach considering distillate oil is commercial grade heating oil. EPA has no justification to impose upon ICI users of commercial fuel oil the emissions reductions that are not imposed on other uses of the same fuel oil. If EPA determines that restrictions are justified, those restrictions should be placed on the suppliers of the distillate oil to meet any limitations in quality without back-end cleanup equipment.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Comment: DP&L strongly recommends that the EPA modify its Proposed Rule to include a limited use exception similar to the exception established under the RICE Rule, 40 CFR 63.6590. Under the Proposed Rule, smaller oil-fired auxiliary boilers that run rarely would be required to comply with stringent emissions limits as in Table 1 and 2 of Subpart DDDDD and demonstrate compliance with those limits in Table 4 of Subpart DDDDD by following expensive monitoring and testing requirements.
The cost of such monitoring and testing is prohibitively expensive for small limited use boilers. DP&L's distillate fuel fired auxiliary boilers have a heat input range of 70 -90 MMBtu per hour and each one is used less than 200 hours per year.

Comment: EPA should, however, take the necessary next step and extend the work practice approach to all gas-fired units. Despite the exceedingly strict emissions limits that are proposed, EPA has not identified a demonstrated path to compliance for the remaining gas-fired units for which EPA has not proposed to make work practices available. Rather than imposing undue and unrealistic costs and standards on these remaining gas-fired boilers, EPA should allow work practices rather than require emissions limitations.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2699.1, excerpt 1 for a response to work practices for all gas units.

Comment: In lieu of numerical emission limits, EPA should establish reasonable limits for PM and alternative good combustion practice and tune-up requirements for other HAPs for biomass units, just as it has proposed for units that combust natural gas. In justifying its decision to apply work practice standards in place of emission limits for gas boilers and process heaters, EPA cites a potential cost of over $14 billion for installing controls to meet such limits. EPA further notes that control requirements would provide a disincentive for fuel switching to gas as a control option for other fuel subcategories, and could even encourage some facilities to switch from gas to a cheaper fuel such as coal2. This rationale could also apply to biomass boilers and therefore provides ample support for adopting work practice standards in lieu of emission limits for boilers that burn biomass.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits. Refer to DCN EPA-HQ-OAR-2002-0058-2882.1, excerpt 7 for a response the cost impact to the forest products industry.

Comment: A work practice standard should also be extended to industrial boiler units burning coal-derived gas. Utilities are increasingly being asked to consider constructing integrated gasification combined cycle ("IGCC") units. These units include a coal gasifier that produces gas for later combustion in a gas turbine. The gas from an IGCC unit is cleaned prior to combustion, so is not much different than natural gas or refinery gas in terms of trace HAPs. EPA should add coal-derived gas to the fuels in the Gas 1 category.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2699.1, excerpt 1 for a response to work practices for all gas units.

Comment: EPA proposes work practice standards for clean gas (Gas 1) boilers rather than MACT limits because the extreme cost to comply with MACT will be a disincentive to switch to a cleaner gas fuel. We agree with this decision, but also believe that the same determination is justified for biomass boilers. The severe economic impact on forest products and other industries that operate biomass boilers will be a disincentive to continue to operate or expand the use of biomass boilers.

Comment Excerpt Number: 16

Comment: Limited use boilers operate for only short periods of time and cannot feasibly be tested pursuant to EPA standards. Work practices should therefore serve in lieu of emission monitoring and control technology for these boilers. As stated in the Clean Air Act, "if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice, or operational standard, or combination thereof, which in the Administrator's judgment is consistent with the provisions of subsections (d) or (f) of this section." 42 U.S.C. 7412(h). The D.C. Circuit Court of Appeals has affirmed EPA's authority under CAA section 112(h) to use work-practice standards instead of emission floors where "measuring emission levels is technologically or economically impracticable." Sierra Club v. EPA, 479 F.3d 875, 884 (D.C. Cir. 2007).
In the recently promulgated CI RICE MACT, for example, EPA set work practices including regularly scheduled maintenance and the cataloging of hours of operation to ensure compliance with relevant emission limits for emergency use engines. See 75 Fed. Reg. at 965556. As stated by EPA, "EPA believes that work practices are appropriate and justified for this group of stationary engines because the application of measurement methodology is not practicable due to technological and economic limitations." Id. at 9556. As further stated by EPA:
[U]sing these [test] procedures would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.

Id. at 9661 [Footnote: It is worth noting that these exceptions were not created because the emissions generated have no impact on the environment. As EPA found, "[t]he majority of stationary CI engines are used for emergency purposes. EPA has estimated that 80 percent of stationary CI engines are emergency engines and EPA has taken steps in the final rule to reduce the burden on owners and operators of these engines." 75 Fed. Reg. at 9658. Rather, the basis for promulgating work practices in lieu of emission standards was the impracticality of prescribing or enforcing an emission standard. See 42 U.S.C. 7412(h).]

Response: EPA agrees with the commenter that it is not feasible to prescribe or enforce a numeric emission limitation on limited use units. Limited-use boilers and process heaters must complete a biennial tune-up as specified in §63.7540. They are not subject to the emission limits in Tables 1 and 2 to this subpart, the annual tune-up requirement in Table 3 to this subpart, or the operating limits in Table 4 to this subpart. See the preamble for a discussion of limited use units.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-2808.1
Comment Excerpt Number: 17

Comment: Like emergency CI RICE, limited use boilers cannot feasibly accommodate the Boiler MACT rule's testing obligations without running for a considerably longer period than they would typically otherwise operate. Averaging less than 50 hours per month and operating as few as 15 hours per month, as is the case for the Painesville limited use unit, does not leave time for the full measure of emission tests required for solid fuel-fired units. The majority of those hours

for limited use units arc in start-up or shut-down modes that are not the steady state conditions required. 75 ed. keg. at 32052 (proposed 40 C.F.R. 63.7520(d)). [Footnote: Even during regular operation, a limited use boiler would still need to operate for at least 12 hours in steady state condition in order to accommodate the variability attendant in these performance tests. See 75 Fed. Reg. at 32033 (stating that EPA selected a 12-hour averaging period for demonstrating continuous compliance "to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits")] Like limited use engines. these boilers vmuld be required to extend steady state operation beyond routinely scheduled operation, thereby unnecessarily increasing emissions just to conduct the testing required by Boiler MACT. A work practice is necessary and justified because it is not technologically and economically feasible to test these sources during routine operations.

Limited use boilers cannot meet the proposed MACT floors. EPA is proposing that boilers and process heaters with heat input capacities greater or equal to 100 mmBtu/hr "demonstrate that average CO emissions, on a 30-day rolling average, are at or below the proposed CO limit." 75 Fed. Reg. at 32034. This averaging period is essential to accommodating expected data variability, including SSM events. See, e.g., 69 Fed. Reg. at 5521; see also Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 102 (rejecting a 24-hour averaging period because a 30-day rolling average "accounts for the variability in fuel characteristics (e.g., moisture, Btu content, mixture) that occur for solid fuel-fired boilers and process heaters"). Measuring CO levels for 15-50 operating hours per month could not reasonably be expected to meet the same emission limits due to their reduced ability to accommodate fuel variability. As a result, operators of limited use boilers may be compelled to operate these boilers substantially longer than would otherwise be necessary to account for fuel and operations variability already factored into the tests conducted at continuously operated units.

Limited use units also present technological and economic obstacles to measuring emissions. Under 40 C.F.R. 63.7545(d) of the Proposed Rule, a Notification of Intent must be submitted at least 30 days before any performance test. See 75 Fed. Reg. at 32060. Due to this requirement, even if a limited use boiler was operated for an entire month after an unplanned start, there would be no time to conduct a properly noticed performance test.

Given the operational characteristics of limited use boilers, their sporadic and unpredictable use, the limited duration of each use, and their need for regular maintenance and readiness testing during periods of prolonged disuse, these units cannot reasonably be expected to use the measurement methodology or meet emission standards achieved by the best performing continuously operating boilers in any fuel or size category. Operators should not be forced to abandon limited use boilers, or to run them for substantially longer periods of time than they are needed for power generation in order to demonstrate MACT compliance. Abandonment of limited use utility boilers would substantially reduce the stability of the power grid, particularly during times of peak demand and for those public services where power is most necessary. On the other hand, forced extraneous operation would result in an increase in emissions, which EPA has already found renders "the application of measurement methodology . . . not practicable." 75 Fed. Reg. at 9661. Work practices consisting of tune-up and performance indicators are therefore the most feasible control for limited use boilers and should be adopted in the final rule.

Comment: We understand that industry representatives have submitted, and are likely to submit, comments in each of these dockets asking that sources combusting biomass be treated differently from sources burning other fuels. Some of these comments seek either broad exemptions, or less stringent forms of regulation, under sections 112 and 129 on the basis that biomass combustion is purportedly “carbon neutral,” renewable, or otherwise environmentally beneficial.

EPA should reject these invitations to indulge in impermissible policy judgments that go beyond the text and purpose of the Clean Air Act. EPA has no authority under either section 112 or 129 to promote one type of combustion over another as a policy matter by imposing inequitable regulatory burdens on sources burning different fuels. Hazardous pollutants are hazardous pollutants, and they pose a danger to human health and the environment regardless of the fuel that produces them. Nothing in sections 112 or 129 authorizes EPA to waive or otherwise weaken MACT standards because either the agency or a regulated source category believes a fuel to have other desirable characteristics. By the same token, EPA should reject industry arguments that work practices or other alternative standards should be adopted for biomass facilities in place of MACT. There has been no demonstration that MACT is not feasible for these facilities within the meaning of section 112(h)(2).

Commenter Name: David Z. Skolasinski

Commenter Affiliation: Cliffs Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-2881.1
Comment Excerpt Number: 3

Comment: Because of the standard operating procedures for the boilers as described above, it is impossible to conduct a stack test consisting of three 4-hour runs while operating the boilers at steady-state conditions near their maximum operating capacity. Because of the boiler operating cycles it is virtually impossible to even conduct a stack test consisting of three 1-hour runs. To conduct three 4-hour stack test runs, would require 12 hours of actual stack testing with one to two hours between test runs to process the collected samples, clean the equipment, and set up for the next test run. The entire process would require 15-18 hours to complete and would typically occur over a two-day period to allow reasonable working hours for the stack testing crew.

It is simply not possible to operate the boilers longer or at higher capacity than that called for to achieve the desired amount of heat in the buildings. To do so would result in exceedingly high temperatures in the buildings, which would create an unacceptable work environment in the offices as well all other buildings. There is also, no way to dissipate the heat generated by the boilers other than directing it into the building heating systems. Even if the heat could be dissipated in some other manner, it would result in a wasteful use of the fuel, which would generate unnecessary emissions of the very constituents the Boiler MACT is intended to limit. It would also result in the unnecessary generation of green house gasses and criteria pollutants, which is contrary to U.S. energy policy.
To further complicate matters the large heating boilers must be tuned up during the summer months when they are not in use. At Cliffs' mines this effort typically requires approximately 150 man-hours per boiler to dismantle the boiler, clean it, and reassemble it. In reality, the process typically requires three to four weeks per boiler with the maintenance crew working 8 hours per day and having to devote time to other maintenance tasks as well. Before the boiler can be reassembled, it must be inspected for safety and insurance purposes by a licensed state boiler inspector. Even if stack testing could be accomplished, stack tests must be scheduled several months in advance with stack testing firms. This is due to the high demand for stack testing required by numerous Clean Air Act regulatory requirements. As a result, during the heating season, operation of the boilers during a scheduled stack test is dictated by the weather conditions that occur during the stack test period.

If stack testing were even possible, the desired approach would be to arrange for a stack testing firm to conduct stack tests on all relevant boilers at a mine during a single campaign. This controls the cost of mobilization and demobilization associated with travel by the contractor to and from the mine and set up for the test. To conduct three 4-hour run stack tests on just three boilers for PM, CO, and dioxin/fiiran would require one week and would cost approximately $50,000. If an attempt was made to conduct the stack tests and the proper boiler operating requirements could not be reached and maintained, the tests would be considered invalid, and the money and effort would be wasted.

For the reasons outlined above, Cliffs strongly recommends that the final Boiler MACT Rule require only annual tune-ups of large oil-fired heating boilers with no emission limits or associated stack testing. The requirements should be the same as those for large gas-fired boilers.

Devoting resources to annual tune-ups of these boilers is the only practical and cost effective approach to controlling their emissions. While Cliffs has no experience with similar large solid fuel-fired heating boilers, it assumes that these boilers operate in a similar fashion to oil-fired heating boilers. Cliffs recommends that EPA investigate this matter, and assuming Cliffs' assumption is correct, EPA should also regulate these solid fuel-fired boilers the same as large gas-fired heating boilers.

Commenter Name: Byron T. Burrows
Commenter Affiliation: Tampa Electric Company
Document Control Number: EPA-HQ-OAR-2002-0058-3129
Comment Excerpt Number: 4

Comment: Tampa Electric urges EPA to exempt these operations or create a limited use subcategory for auxiliary boilers subject only to limited work practice standards. The limited use subcategory could have a 10% capacity factor threshold based on 10% of the maximum hourly heat input of the boiler multiplied by 8760 hours per year. Alternatively, distillate oil-fired boilers that operate in a warm standby mode (less than 10 mmBtu/hour) a majority of the time could be subject only to work practice standards.

Comment: EPA should, however, take the necessary next step and extend the work practice approach to all gas-fired units. Despite the exceedingly strict emissions limits that are proposed, EPA has not identified a demonstrated path to compliance for the remaining gas-fired units for which EPA has not proposed to make work practices available. Rather than imposing undue and unrealistic costs and standards on these remaining gas-fired boilers, EPA should allow work practices rather than require emissions limitations.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2699.1, excerpt 1 for a response to work practices for all gas units.

Comment: Use the existing EPA authority to adopt a work practice standard instead of a numeric emission limit for instances where the application of a measurement methodology to a particular HAP is not practical due to technology and economic limitations.

Response: In the final rule EPA has adopted is requiring a work practice standard for particular classes of boilers and process heaters where it has determined the application of a measurement methodology is impractical. See the preamble for justification of the work practice standards and the classes of boilers and process heaters that are eligible for the tune-up in the final rule.

Comment: EPA should establish annual tune-up work practice as the MACT standard for biomass boilers. For example, in the forest products industry alone, the estimated cost of complying with the proposed HAP emissions limitations for biomass boilers is $3.3 billion. This is an extraordinary cost that, in the context of the forest products industry, equals or exceeds the magnitude of the economic burden that EPA predicts for the Gas 1 subcategory. Similarly severe economic impacts are expected in other industry sectors where biomass boilers are widely use, such as the furniture, sugar, and agricultural products industries. Thus, there is strong economic justification for prescribing work practice standards for biomass boilers in lieu of numeric emissions limitations.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Comment: Limited-use auxiliary boilers should be treated in a similar fashion as gas-fired auxiliary boilers. Electric utility operated auxiliary boilers will be subject to the ICI Boiler MACT rule because they are not steam generating units that produce electricity. As noted above, our auxiliary boilers combust either natural gas or distillate fuel and operate infrequently normally during EGU startups or to provide station heat. As a result, the HAP emissions from auxiliary boilers are very low and do not pose any risk to public health.

Under the proposed rule, gas-fired auxiliary boilers are subject to work practice standards requiring an annual tune-up. By contrast, the proposed ICI Boiler MACT rule requires oil-fired auxiliary boilers to comply with stringent ICI Boiler MACT emission limits and demonstrate compliance with those limits by implementing expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not produce environmental benefits.

EPA should create a limited use subcategory for auxiliary boilers combusting distillate fuel that would subject those units to the same work practice standards as gas-fired boilers. Eligibility for this subcategory should be determined based on 10 percent of the maximum hourly heat input of the boiler multiplied by 8760 hours per year.

Comment: The proposed rule would encourage a switch away from renewable, GHG-neutral biomass fuel to increased fossil fuel use, either domestically or overseas. In the case of the Gas 1 subcategory EPA explained that establishing a work practice standard in lieu of emission limitations is justified because it avoids counterproductive results such as switching to “dirtier” fuels. The AHFA agrees with this conclusion, and we believe it applies to dry biomass as well. By implementing work practice standards rather than a stringent emission limitation for the dry biomass subcategory, the EPA will avoid a switch away from renewable to fossil fuel sources, a switch away from GHG neutral fuels to a much larger carbon footprint, and a movement of domestic production to overseas locations.

Comment: For the reasons discussed above, EPA should establish annual tune-up work practice as the MACT standard for all other gas boilers. Other gas boilers have the same characteristics as natural gas and refinery gas. Indeed, EPA has not identified and cannot identify any technologically feasible means of achieving the stringent proposed standards that apply to all of the units in the subcategories. As discussed infra (Section II.B), EPA is therefore required to turn to other methods of control, with tune-ups as the choice justified by EPA's data. Further, many of the other gases are very similar in composition and combustion properties to the Gas 1 subcategory gasses, making a decision to have such dramatically different emission control regimes arbitrary and capricious. Finally, gaseous fuels are clean burning fuels with emissions that are lower than from other types of fuels. Just as EPA recognized that it should not be creating perverse incentives that force operators to turn away from clean Gas 1 fuels, 75 Fed. Reg. 32025, EPA should not create regulatory incentives for operators to turn away from other clean gaseous fuels. EPA should encourage the use of clean burning fuels by allowing work practices that give operating flexibility to maximize combustion efficiency and, thereby, minimize emissions.

Comment: The forest products industry estimates it will cost $3.3 billion to comply with the proposed HAP limits. This is a severe cost to impose on a single industry. Similar severe costs

are expected to result from other industry groups that bum biomass, if pollution controls must be added to comply with HAP emission standards, such as the furniture industry, sugar industry, and agricultural products industries. These control costs would lead many of.the existing biomass boiler`owners to stop burning biomass or discourage companies from switching to renewable fuels such as biomass. This also contradicts U.S_ policy
objectives to reduce our nation's reliance on fossil fuels. Biomass is a clean fuel with low concentrations of naturally occurring metals, and it is also a fuel with no net increase in the generation of greenhouse gas emissions when it is burned, therefore, we can reduce our nation's carbon footprint by encouraging the use of biomass as a fuel instead of discouraging its use by requiring expensive pollution controls to meet stringent HAP limits.

Response: EPA has revised its cost estimates in the final rule. See the preamble and RIA for revised cost estimates and response to comments on the cost issues.

With respect to the larger policy concerns on promotion of biomass, the carbon footprint of biomass and US energy policy is outside the scope of this rulemaking and will not be responded to in this document.

Comment: Instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels (the "Gas 1" subcategory), EPA proposes to adopt work practices requiring an annual tune-up of the boiler. For units larger than 100 mmBtu/hr, EPA explains that "the capital costs estimated for installing controls on these boilers and process heaters to comply with MACT limits for the five HAP groups is over $14 billion." EPA therefore proposed that work practice standards are appropriate and justified for units in the Gas 1 subcategory out of concern for the cost of complying with numeric emissions limitations and based on the adverse policy incentives that would be created.

The rationale that supports the proposed approach for the Gas 1 subcategory applies equally well to biomass boilers and, therefore, provides ample support for adopting work practices instead of numeric emissions limitation for biomass boilers. For example, in the forest products industry alone, the estimated cost of complying with the proposed HAP emissions limitations for biomass boilers is $3.3 billion. This is an extraordinary cost that, in the context of the forest products industry, equals or exceeds the magnitude of the economic burden that EPA predicts for the Gas 1 subcategory. Document Control Number: EPA-HQ-OAR-2002-0058-2811.1
Comment Excerpt Number: 9

Comment: Should the Agency feel compelled to press forward under § 112(h) despite its authority to establish work practice-based emissions standards directly under §§112(d) and 302(k), the Proposed Rule's findings regarding the infeasibility of controlling and monitoring emissions from natural gas-fired boilers are equally applicable to coke oven gas-fired units. As found by EPA, work practices should supplant numeric emission limits on Gas-1 units because "[f]irst, the capital costs estimated for installing controls on these boilers and process heaters to comply with MACT limits for the five HAP groups is over $14 billion.'..." 75 Fed. Reg. at 32025. Second, EPA found that proposing emission standards for gas-fired boilers and process heaters "would have the negative benefit of providing a disincentive for switching to gas as a control technique (and a pollution prevention technique)" and "may have the negative benefit of providing an incentive for a facility to switch from gas (considered a 'clean' fuel) to a 'dirtier' but cheaper fuel (i.e., coal)." Id. As EPA correctly found, "[i]t would be inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular, to adopt requirements that would result in an overall increase in HAP emissions." Id.

These same arguments apply with even greater force to coke oven gas-fired units. First, the costs of controlling coke oven gas-fired units are similar to the per-unit costs faced by Gas-1 units. Just like Gas-1 units, coke oven gas units would otherwise face the need to install activated carbon injection with fabric filters to control PM, mercury, and dioxin/furan, as well as wet scrubbers to control HC1, and an oxidizing catalyst to control CO - all at a cost well beyond that already calculated by EPA. [Footnote: A model coke oven gas-fired boiler would face an annual cost of $8.4 million with capital costs of $27.7 million to install the controls required for the proposed emission limits. See Table 5. The annual cost for mercury controls alone are over $6.2 million, which means the Proposed Rule is requiring over $250,000 in annual control cost for every pound of mercury reduced from coke oven gas-fired boilers.] ArcelorMittal's Burns Harbor facility alone faces over $100 million in control costs to meet the proposed limits. Second, as discussed above, imposing emission standards on these units would clearly incentivize operators to cease burning coke oven gas in preference for the fossil fuels that cost less to burn, resulting in an increase in emissions "inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular." Id.

But unlike natural gas, which is generally stored as a commodity when not consumed, coke oven gas must be flared as a waste gas to ensure a safe environment if not immediately usable at a facility. As a result, creating incentives which cause operators of coke oven gas-fired units to fuel-switch (even to natural gas) would result in significant net emissions increases. That is because the facility would necessarily combust both the coke oven gas (at a flare) and the additional fossil fuel necessary to generate sufficient heat for its operations. Simply put, any standard that creates a disincentive to recover energy from process gases is bad for the environment and thus contrary to the goals of the Clean Air Act. Extending work practice tune-up standards to coke oven gas boilers will ensure that there is no environmentally-detrimental incentive to displace coke oven gas with natural gas in the boiler and flare the coke oven gas.

When the result of imposing an emission standard on a class of sources is to create economic and technological incentives that compel the operator to move the source of emissions out of the affected source and to a flare, it is no longer feasible to prescribe or enforce that emission standard. Section 112(h) of the Act allows work practices in lieu of emission standards in this circumstance. Unquestionably, EPA can justify a work practice under 112(h)(2)(B) of the Act because the "application of measurement methodology to [these boilers] is not practicable due to technological and economic limitations." HAP emissions from coke oven gas combustion cannot be measured with any methodology applied at the boiler when they are occurring at the flare. EPA may apply work practices under 112(h) to ensure that coke oven gas is not driven out of the boiler and to a flare.

Comment: MPU recommends EPA retain the limited use subcategory as finalized in the 2004 Boiler MACT rule. MPU operates boilers in varying configurations, with some units used to backup primary units to ensure reliable electricity generation at all times. These backup units typically operate less than 10% of the time and in response to the scheduled and unscheduled downtime for primary units. These units are part of the standby capacity of a transmission network that must be reliably available to support the electric grid when need is determined by the transmission operator. These units must be operated periodically to ensure they will be reliably available upon demand to support the grid. MPU encourages EPA to adopt a limited use subcategory that acknowledges the unique challenges associated with monitoring and measuring emissions from these sources. Work practices under 112(h) are needed and appropriate for limited use public power units operating less than 10% of their annual heat input capacity to ensure reliable and efficient electricity service.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2761.1, excerpt 4 for a response to tune-up frequency for limited use combustors.

Comment: Coke Oven Gas-Fired Units Also Satisfy the CAA §112(h) Work Practice Requirements Because Measurement Methodologies Are Insufficient to Reliably Quantify Their Controlled Emission Levels.

EPA may also justify work practices for coke oven gas-fired boilers on the basis that emissions after control will be below the levels that can be reliably measured. EPA should establish a work practice standard for coke oven gas-fired units because measurement of controlled emission levels after application of emission controls to achieve proposed emission limits is technically and economically infeasible.

EPA is directed to use work practices under CAA 112(h) when "application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." When conducting a series of tests on coke oven gas-fired boilers using EPA's designated test methods in July 2010, the measurement methodology could not accurately and reliably measure concentrations for some compounds at the low levels necessary to demonstrate compliance with the proposed emission limits. Uncontrolled concentrations for coke oven gas-fired units are very low, but not low enough to meet the proposed emission limits. When applying the emission control measures assumed in EPA's Regulatory Impact Analysis, the controlled concentrations are expected to be well below the level that can be reliably measured by EPA test methods and laboratory analytical procedures. The factors that determine the levels that can be reliably measured by a measurement methodology cannot be controlled and it is economically infeasible to conduct repeated tests hoping that these factors will randomly result in acceptable detection and quantitation limits. Replacing the Gas-2 numeric emission limitations with a work practice standard for coke oven gas-fired units provides a reasonable pathway to compliance with Boiler MACT requirements.

Comment: Though Citizens commends EPA for attempting to provide for operational variability by averaging the CO concentration over a 30-day period, the proposed limits, even when a longer averaging period is considered, will be difficult to achieve given the variability in operation over a broad load range and the impacts that this has on CO emissions and combustion efficiency.

Citizens recommends that in lieu of a single limit for CO concentration (in parts per million) using a CO CEMS to demonstrate continuous compliance, that EPA utilize a work practice standard (i.e. tuning the system to maximize combustion efficiency over the load range typical for each boiler). The typical load range can be determined using historical plant data or even the load bin-type calculations used in the Part 75 regulations. To ensure continuous compliance with the "good tuning" achieved through the work practice, the source could use the CO CEMS to monitor emissions through the use of a typical range of CO (based on boiler load) for the individual unit immediately after the tune-up.

Response: EPA recognizes the inconsistency in the proposal that established a CO limit based on stack test results but required compliance demonstration with a CO CEMS. We also recognize the sensitivity of CO levels as a function of boiler load. The final rule no longer includes a requirement for a CO CEMS. Although the we appreciate the commenter suggestion to use load bin-type calculations used in the Part 75 regulations, those calculations apply to mostly very large boilers and process heaters and would be difficult to implement for load-following units that experience frequent load swings. Instead, EPA has included an O2 monitoring requirement in the final rule in order to ensure continuous compliance with good combustion efficiency on the unit.

Comment: NAFO recommends that, in the final rule, EPA eliminate the biomass unit emission limits requirements for dioxin/furan and mercury for biomass, and replace them with work practice requirements. Section 112(h)(2)(B) of the CAA authorizes EPA to establish work practice standards when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." The proposed standards are not practicable due to technological limitations.
The proposed rule already adopts work practice standards for other fuel sources. For natural gas-fired units, the proposed rule would establish a work practice standard instead of emission limits. As such, operators would be required to conduct annual or biennial tune-ups for each unit instead of adopting add-on controls. NAFO believes that for dioxin/furan and mercury, EPA's rationale that supports establishing work practice standards for natural gas-fired units applies equally well to biomass units. EPA explained in the preamble that for gas-fired units larger than 100 mm Btu/hour, "the capital costs estimated for installing controls on these boilers and process heaters to comply with MACT limits for the five HAP groups is over $14 billion." 75 Fed. Reg. at 32025. EPA further explains that "emission limits on gas-fired boilers and process heaters may have the negative benefit of providing an incentive for a facility to switch from gas (considered a 'clean' fuel) to a 'dirtier' but cheaper fuel (i.e., coal)." Id. NAFO believes that for certain HAPs a work practice standard (instead of numeric emissions limitations) is similarly warranted for biomass units. Like gas-fired units, the cost of compliance with the dioxin/furan and mercury limitations for biomass units would be extraordinary. In addition, as described above, prescribing work practice standards would avoid creating an incentive for facilities to switch from biomass, a "clean" fuel, to a higher-carbon fossil fuel. Accordingly, for dioxin/furan and mercury, EPA should establish work practices rather than emissions limitations for biomass boilers.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits. Refer to DCN EPA-HQ-OAR-2002-0058-2882.1, excerpt 7 for a response the cost impact to the forest products industry.

Commenter Name: Edward E. Quick

Comment Excerpt Number: 13

Comment: Work practice standards are the appropriate means of regulating distillate oil and similar fuels for a number of reasons.

First, distillate oil (No.2 Oil) is a commercially available fuel that is regulated by ASTM specifications. It is commonly used for commercial and residential heating purposes as well as by industrial, commercial, and institutional boilers and process heaters. HCI and Hg emissions are a function of chloride and mercury content of the fuel. Although chloride and mercury are not included in the ASTM specification, No. 2 oil is inherently low in these compounds by means of the refining process as dictated by the ASTM specification.

Second, work practices have been the preferred method for regulating boilers and process heaters firing distillate oil. In the past, EPA has considered distillate oil in a manner similar to natural gas when establishing requirements for emissions controls. Celanese is not aware of any boilers or process heaters fired with distillate oil, alone or in combination with gaseous fuels, that have been required to install emission controls for PM, mercury, or HCI.

Third, none of the distillate oil-fired units in the MACT floor database are equipped with PM or HCI controls. EPA reference documentation provides no basis for imposing PM and HCI emissions limits on distillate or diesel oil fired boilers and process heaters. Conversely, units firing residual oil have been required to install PM controls and acid gas scrubbers. Therefore, by grouping all liquid fuels into one category, it appears that EPA arbitrarily imposed emission limits that are based on controlled units firing residual oil onto units firing distillate oil.
Fourth, EPA recognizes that distillate oil fired units are inherently lower emitting devices that would likely meet the proposed limits by not requiring performance testing and initial compliance requirements. Since EPA recognizes that emission controls will not likely be required for distillate oil fired units, there is no purpose served by imposing those limits. The imposition of superfluous emissions limits results only in the expense and effort of unnecessary regulatory, enforcement, and compliance demonstration.

Finally, PM and HCI emission rates for distillate oil fired units are very low and, for the most part, are not controllable by the source. In other words, they could legitimately be considered de minimis.
Based on these considerations, Celanese recommends that EPA revise the requirements in the final rule and impose work practice standards for distillate oil and comparable fuels rather than emission limits. The justification for this approach is the same as for the Gas 1 category. This could be done by separating distillate oil and comparable fuels into an oil 1 category, and placing heavy residual oils into an oil 2 category.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Commenter Name: Edward E. Quick

Comment Excerpt Number: 14

Comment: Comparable fuels should be treated the same as distillate oil relative to work practice standards. EPA established final rules revising the standards for Hazardous Waste Combustors on June 19, 1998 (63 Fed. Reg. 33781-33829) to exclude “comparable/syngas fuel” from 40 CFR 261.4 and providing specific requirements 40 CFR 261.38. As explained in the preamble to that rule, EPA used a composite specification for establishing the limits for comparable fuels.

These fuel specifications limit fuel concentrations of halogens, metals, and other compounds and therefore prevent adverse impacts to the environment. Therefore, Celanese recommends that work process standards apply to process liquid fuels meeting the comparable fuels limits.

Comment: Annual stack testing is excessive, especially for liquid-fueled units with low hours of operation. In fact, for units burning distillate fuels, periodic stack testing would be of questionable utility. Instead, we suggest extending the work practice for periodic unit tune ups to boilers burning distillate oil and biodiesel fuels. This would ensure the units are operating optimally, leading to the desired environmental benefits, while sparing these units from the cost of testing.

Comment: The work practice standard should be extended to industrial boiler units burning coal-derived gas. Utilities are increasingly being asked to consider constructing integrated gas combined cycle (“IGCC”) units. These units include a coal gasifier that produces gas for later combustion in a gas turbine. The gas from an IGCC unit is cleaned prior to combustion so in terms of trace HAPs it is little different than natural gas or refinery gas.

In fact, some coal-gasification processes include an additional methanation step that results in the production of synthetic natural gas (“SNG”). This product is indistinguishable from natural gas and can be transported in natural gas pipelines. The proposed distinction between natural gas and other gas sources (like SNG) could create future compliance problems. How will an industrial boiler end user know whether the pipeline delivered gas containing some amount of SNG and thus whether the industrial boiler is subject to work practice standards or emission limits?

The proposed gas distinction is unworkable. All gas-fired boilers should be subject to work practice standards. If, however, EPA decides to keep the proposed distinction between gas sources, then EPA should add coal-derived gas to the fuels in the Gas 1 category.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2699.1, excerpt 1 for a response to work practices for all gas units.

Comment: EPA should adopt a work practices standard for the limited use subcategory for two reasons:
* EPA has acknowledged that there is no proven control technology for organic HAP emissions from limited use units.
* Limited use units, such as emergency and backup boilers, cannot be tested effectively due to their limited operating schedules and because most EPA test methods require a unit to operate in a steady state (See Proposed 40 CFR 63.7520(d)).

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2808.1, excerpt 16 for a response the request for work practices not emission limits for limited-use combustors.

Comment: The proposed IB MACT rule requires oil-fired auxiliary boilers to comply with stringent emission limits and demonstrate compliance with those limits by following expensive monitoring requirements. The distinction between these two different types of auxiliary boilers is unnecessary and does not produce environmental benefits.

Believes EPA should create a limited use subcategory for boilers
combusting distillate fuel that would subject those units to the same work practice standards as gas-fired units. The limited use subcategory should have a 10 percent capacity factor threshold. Eligibility for this subcategory would be determined based on 10 percent of the maximum hourly heat input of the boiler multiplied by 8,760 hours per year. Providing a limited use category with the limitations described above, would not pose any risk to human health but would provide substantial economic and administrative relief to owners of these sources.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2808.1, excerpt 16 for a response the request for work practices not emission limits for limited-use combustors.

Comment: EPA has proposed that work practice standards are appropriate and justified for units in the Gas 1 subcategory out of concern for the cost of complying with numeric emissions limitations and based on the adverse policy incentives that would be created. The rationale that supports the proposed approach for the Gas 1 subcategory applies equally well to biomass boilers and, therefore, provides ample support for adopting work practices instead of numeric emissions limitations for biomass boilers.

Use of biomass reduces net GHG emissions, which makes the combustion of biomass an important tool in managing and reducing the Nation's carbon footprint. Similarly, biomass is an abundant, renewable domestically-produced fuel that can help reduce reliance on foreign sources of fossil fuel and, thus, improve the Nation's energy security. Prescribing stringent HAP emissions limitations on biomass boilers will create a significant barrier to the continued use and expansion of biomass fuels and incentivize the use of less desirable fossil fuel alternatives.

Given the high costs of complying with the proposed HAP emissions limits for biomass boilers and the strong energy and environmental policy benefits off biomass, EPA has ample justification for requiring work practices rather than HAP emissions limitations for biomass boilers.

The proposed standards will drive energy facility managers to avoid or abandon biomass for natural gas. This will reduce fuel flexibility and the associated economic and reliability benefits of using biomass. Dependence on one fuel increases risks relative to price fluctuations and supply disruption.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Comment: As stated in the Clean Air Act, "if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment,

work practice, or operational standard, or combination thereof, which in the Administrator's judgment is consistent with the provisions of subsection(d) or (f) of this section. 42 U.S.C. § 7412(h). While
the D.C. Circuit Court of Appeals has ruled that EPA cannot set floors of "no control," the court also affirmed EPA's authority under CAA § 112(h) to use work-practice standards instead of emission floors where "measuring emission levels is technologically or economically impracticable." Sierra Club v. EPA, 479 F. 3d 875, 884 (D.C. Cir. 2007). Given the limited and sporadic operation of emergency and backup boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should be limited by work practices in lieu of an emission floor.

In the recently promulgated CI RICE MACT, EPA set work practices including regularly scheduled maintenance and the cataloging of hours of operation to ensure compliance with relevant emission limits for emergency use engines. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed.Reg. at 9655-56. As stated by EPA, "EPA believes that work practices are appropriate and justified for this group of stationary engines because the application of measurement methodology is not practicable due to technological and economic limitations." Id. at 9556. As further stated by EPA: [U]sing these procedures would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ. Id. at 9661.

Similarly, as stated in the memorandum entitled Existing Stationary Non-Emergency CI RICE Less Than 100 HP and Existing Stationary Emergency CI RICE Located at Major Sources and GACT for Existing Stationary CI RICE Located at Area Sources (February 15, 2010) cited in EPA's final rule: For existing stationary CI emergency engines located at major sources, EPA determined it is not feasible to prescribe or enforce an emission standard because the application of measurement methodology to this class of engine is impracticable due to the technological and economic limitations. Emergency engines typically only operate during emergencies or during periods of routine testing and maintenance. EPA determined that application of the emissions measurement methodologies during either of these periods is not practicable. It is impracticable to test emissions from stationary CI emergency engines during periods of routine testing and maintenance using the test procedures specified in the rule because it would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.

EPA also excluded black start units from HAP emission regulations in the CI RICE MACT rule. While these units operate whenever a turbine generator starts, and therefore are not limited to emergency operations, EPA nonetheless recognized the importance of exempting these units from numeric HAP standards, finding that "the short time of operation for these engines (10–15 minutes per start) makes application of measurement methodology for these engines using the required procedures, which require continuous hours of operation, impracticable. Requiring numerical emission standards for these engines would actually require substantially longer operation than would occur normally in use, leading to greater emissions and greater costs." National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed.Reg. at 9662.

It is worth noting that these exceptions were not created because the emissions generated have no impact on the environment. As EPA found, "[t]he majority of stationary CI engines are used for emergency purposes. EPA has estimated that 80 percent of stationary CI engines are emergency engines and EPA has taken steps in the final rule to reduce the burden on owners and operators of these engines." National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed.Reg. at 9658. Rather, the basis for promulgating work practices in lieu of emission standards is the impracticality of prescribing or enforcing an emission standard. See 42 U.S.C. § 7412(h).

Emergency and backup boilers, like emergency and black start CI RICE, are operated for only short periods of time and cannot feasibly be tested pursuant to EPA standards. Work practices should therefore also serve in lieu of emission monitoring and control technology for emergency and backup boilers. For example, under 40 C.F.R. § 63.7545(d) of the Proposed Rule, a Notification of Intent must be submitted at least 30 days before any performance test. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed.Reg. at 32006. As a result, even if a limited use boiler were operated for an entire month after an unplanned start, there would be no time to conduct the necessary performance tests. In addition, most test methods require steady state conditions that may not be achieved during limited use operations and, once a steady state has been reached, would require the boiler to continue operating at steady state for enough time to conduct the three 4-hour test runs required by the proposed rule for most compliance tests. See Proposed 40 CFR 63.7520(d).[29 Even during regular operation, a limited use boiler would still need to operate for at least 12 hours in steady state condition in order to accommodate the variability attendant in these performance tests. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed.Reg. at 32,033 (stating that EPA selected a 12 hour averaging period for demonstrating continuous compliance "to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits").

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2808.1, excerpt 16 for a response the request for work practices not emission limits for limited-use combustors.

Comment Excerpt Number: 37

Comment: In view of the substantially higher costs faced by HOVENSA and other remote oil burning facilities for controls, we believe EPA's logic for gas fired units applies with equal force to these units. If HOVENSA is required to install physical controls for CO, PM, HCl and Hg/dioxins on each of its 23 units, as EPA projects it must do to comply with the proposed rule, an initial project scope prepared by HOVENSA estimates capital expenditures of (values removed as CBI). (See CBI submittal for methodology and spreadsheet used for estimates) This estimate spreadsheet does not include an approximately 1MM per unit cost for monitoring (18 of the 23 units would require 2 CEMS, one for CO and one for PM). And it does not include the likely (values removed as CBI) in operating costs imposed by a PM standard that will force a switch
from residual fuel oil to distillate fuel oil (since residual oil might not be able to meet EPA's stringent standards, even with add-on controls).

Because the 3 to 4 year timeframe required for compliance with a MACT standard and that time period might not coincide with turnaround schedules for many units, this rule will impose additional economic costs for shutting down units to install controls outside of a normal turnaround schedule. Shutting down one unit in a refinery typically has a domino effect requiring shutdown of other units operationally integrated with that unit. For example, if HOVENSA were to have to shut down one of its largest oil burning units, it would affect 3Vac and Coker because they are dependent on that unit for their feedstock. The average cost of an outage day on 5CDU for example is (values removed as CBI) because of its total impact on the facility. Assuming a very short 10 day outage (this is shorter than a normal shutdown) to install controls, the rule results in an additional (values removed as CBI) in costs for that unit complex alone. This forced shutdown process would have to be repeated several times to cover all the potential 23 units affected.

HOVENSA's estimated capital cost of (values removed as CBI) to comply is (values removed as CBI) the ENTIRE capital cost estimated by EPA for ALL 826 affected units and its (values removed as CBI) annual operating cost increase is (values removed as CBI) of the ENTIRE opeasting cost estimate, which included only testing and monitoring. In addition, HOVENSA faces tens of millions of dollars in operating losses from unit shutdowns to install controls. These costs are staggering in magnitude and simply not practicable for any refinery, particularly for HOVENSA. Thus, in addition to subcategorizing these facilities, we believe that these units should be subject to a work practice standard consistent with the standard for gas fired units and metal finishing furnaces.

[Footnote 36: Consistent with the preamble, the cost estimate assumes CO oxidation catalyst, fabric filter and wet scrubber and an injection system for sorbet. If either a fabric filter or wet scrubber can be eliminated, it would change the cost, but the costs would still be of a similar magnitude.]

Response: EPA thanks the commenter for describing the difficulties associated with retrofitting existing units. However, regardless of any information on that topic, the emission standards must reflect the floor level of control. Costs and emission impacts estimated for the boiler MACT standard are intended to represent national impacts. Consequently, costs for a specific facility may be lower or higher than what was estimated but on a national basis, we determined that our estimates are reasonable. We would also note that the cost algorithms include a cost factor for retrofitting existing boilers.

EPA has not expanded work practice standards beyond Gas 1 units. It should be noted that EPA has agreed that the unique considerations faced by non-continental refineries warrant a separate subcategory for these units, where data was made available. In this case, only data for mercury and CO were made available for this subcategory and the emission limits for the other pollutants are based on the data for continental liquid units.

Comment: The MACT floor for limited use boilers should be maintenance work practices because emission limitations are infeasible.

As stated in the Clean Air Act, “if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice, or operational standard, or combination thereof, which in the Administrator’s judgment is consistent with the provisions of subsection(d) or (f) of this section. 42 U.S.C. 7412(h). While the D.C. Circuit Court of Appeals has ruled that EPA cannot set floors of “no control,” the court also affirmed EPA’s authority under CAA 112(h) to use work-practice standards instead of emission floors where “measuring emission levels is technologically or economically impracticable.” Sierra Club v. EPA, 479 F. 3d 875, 884 (D.C. Cir. 2007). Given the limited and sporadic operation of emergency and backup boilers, as well as the technical infeasibility of imposing emission limitations on these units, the limited use subcategory should be limited by work practices in lieu of an emission floor.

In the recently promulgated CI RICE MACT, EPA set work practices including regularly scheduled maintenance and the cataloging of hours of operation to ensure compliance with relevant emission limits for emergency use engines. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 9655-56. As stated by EPA, “EPA believes that work practices are appropriate and justified for this group of stationary engines because the application of measurement methodology is not practicable due to technological and economic limitations.” Id. at 9556. As further stated by EPA:

[U]sing these procedures would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.

Id. at 9661. Similarly, as stated in the memorandum entitled Existing Stationary Non-Emergency CI RICE Less Than 100 HP and Existing Stationary Emergency CI RICE Located at Major Sources and GACT for Existing Stationary CI RICE Located at Area Sources (February 15, 2010) cited in EPA's final rule:

For existing stationary CI emergency engines located at major sources, EPA determined it is not feasible to prescribe or enforce an emission standard because the application of measurement methodology to this class of engine is impracticable due to the technological and economic limitations. Emergency engines typically only operate during emergencies or during periods of routine testing and maintenance. EPA determined that application of the emissions measurement methodologies during either of these periods is not practicable. It is impracticable to test emissions from stationary CI emergency engines during periods of routine testing and maintenance using the test procedures specified in the rule because it would increase the required number of hours of operation of the engine beyond the routinely scheduled reliability testing and maintenance operation, thereby increasing emissions. While emergency engines have periods of operation for scheduled maintenance and reliability testing, those periods are usually several hours shorter than the number of hours that would be required to run the necessary emissions tests under subpart ZZZZ.

EPA also excluded black start units from HAP emission regulations in the CI RICE MACT rule. While these units operate whenever a turbine generator starts, and therefore are not limited to emergency operations, EPA nonetheless recognized the importance of exempting these units from numeric HAP standards, finding that "the short time of operation for these engines (10–15 minutes per start) makes application of measurement methodology for these engines using the required procedures, which require continuous hours of operation, impracticable. Requiring numerical emission standards for these engines would actually require substantially longer operation than would occur normally in use, leading to greater emissions and greater costs." National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 9662.

It is worth noting that these exceptions were not created because the emissions generated have no impact on the environment. As EPA found, "[t]he majority of stationary CI engines are used for emergency purposes. EPA has estimated that 80 percent of stationary CI engines are emergency engines and EPA has taken steps in the final rule to reduce the burden on owners and operators of these engines." National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 9658. Rather, the basis for promulgating work practices in lieu of emission standards is the impracticality of prescribing or enforcing an emission standard. See 42 U.S.C. § 7412(h).

Emergency and backup boilers, like emergency and black start CI RICE, are operated for only short periods of time and cannot feasibly be tested pursuant to EPA standards. Work practices should therefore also serve in lieu of emission monitoring and control technology for emergency and backup boilers. For example, under 40 C.F.R. § 63.7545(d) of the Proposed Rule, a

Notification of Intent must be submitted at least 30 days before any performance test. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32006. As a result, even if a limited use boiler were operated for an entire month after an unplanned start, there would be no time to conduct the necessary performance tests. In addition, most test methods require steady state conditions that may not be achieved during limited use operations and, once a steady state has been reached, would require the boiler to continue operating at steady state for enough time to conduct the three 4-hour test runs required by the proposed rule for most compliance tests. See Proposed 40 CFR 63.7520(d). [Footnotre: Even during regular operation, a limited use boiler would still need to operate for at least 12 hours in steady state condition in order to accommodate the variability attendant in these performance tests. See National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32033 (stating that EPA selected a 12 hour averaging period for demonstrating continuous compliance “to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits”).] Similarly, EPA is proposing that boilers and process heaters with heat input capacities greater or equal to 100 MMBtu/hr “demonstrate that average CO emissions, on a 30-day rolling average, are at or below the proposed CO limit.” National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. at 32034. This averaging period is essential to accommodating expected data variability, including SSM events. See, e.g. National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed. Reg. at 5521. See Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 102 (rejecting a 24-hour averaging period because a 30-day rolling average “accounts for the variability in fuel characteristics (e.g., moisture, Btu content, mixture) that occur for solid fuel-fired boilers and process heaters”). Without the ability to test for 30 continuous days or thereabouts, a limited use boiler could not reasonably be expected to meet the same emission limits due to their reduced ability to accommodate data variability and operators cannot adequately determine compliance with numeric emission limits.

The result would be a marked inability to practically measure emissions without operating these units for significant periods of time for the sole purpose of conducting emissions testing. As with the recently regulated emergency CI RICE, this would result in a new increase in emissions through the very effort to control emissions from these units. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed. Reg. at 9655-56. Work practices are therefore the most feasible control for limited use boilers and should be adopted in the new rule.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2808.1, excerpt 16 for a response the request for work practices not emission limits for limited-use combustors.

Comment: Limited use waste heat boiler.

Manufacturers request, consistent with the above discussion, that EPA require work practices for limited use waste heat boilers. Waste heat boilers use heat extracted from other industrial processes and combust fuel only for a very small duration on an annual basis. For the vast majority of the time, waste heat boilers do not burn alternative fuel at all. For waste heat boilers that primarily use waste heat for their total annual operation, the performance testing requirement (§63.7510 and §63.7520) is unreasonably costly and burdensome. Therefore, the final rule should not require performance testing requirements for limited use boilers that combust liquid fuel less than 10% of the time on an annual basis. The application of work practice standards, is more reasonable and appropriate.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2808.1, excerpt 16 for a response the request for work practices not emission limits for limited-use combustors.

Comment: EPA should subcategorize the proposed liquids subcategory into light liquids and heavy liquids and apply work practice requirements to the clean-burning light liquids subcategory. It is unfair to have distillate units set the floor for heavy oil units. Oil is an expensive fuel compared to gas or coal, and oil is usually only used because gas in not available. For remote locations without access to natural gas (such as islands and Alaska), EPA should only require a work practice for oil units, as EPA proposed for gas-1 for the same reasons EPA cited there. In the Turbine NSPS rule EPA provided some relief for remote locations. For the heavy oil subcategory, only a PM limit is warranted beyond a work practice.

Response: EPA disagrees that it should finalize a work practice standard for liquid fuel units in lieu of emission limits. While EPA recognizes that uncontrolled residual oil-fired units typically have higher PM emissions than distillate oil-fired units, add-on controls are available for these units, as well as pre-combustion technologies to reduce ash and/or metal content of the fuel.

See the discussion of further subcategorizing liquid fuel units in the Rationale for Subcategories section of this document. Also see the discussion of responses to comments for a new non-continental liquid fuel subcategory in the preamble.

Comment: EPA proposes to subject existing small boilers (less than 10 MMBtu/hr heat input) to work practices (tune-ups) in lieu of numerical emission limits and ongoing stack testing. ACC supports this approach and believe that it should be expanded to cover new small boilers as well.

Boilers with heat input less than 10 MMBtu/hr are very small emission sources and the same measurement issues EPA cites for requiring only work practices on existing boilers [75 Fed. Reg. 32024] will also apply to new small boilers. It will not be feasible to measure emissions from these boilers, as the outlet stacks or vents are not likely to meet EPA test method criteria and emissions measured during a 2- to 4-hour stack test are likely below method detection limits for most pollutants being regulated under the rule, and it will be economically infeasible to install controls on these small boilers.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits.

Comment Excerpt Number: 10

Comment: EPA should Adopt Work Practices, not MACT for Biomass Boilers.
EPA proposes work practice standards for clean gas (Gas 1) boilers rather than MACT limits because the extreme cost to comply with MACT will be a disincentive to switch to a cleaner gas fuel. We agree with this decision, but also believe that the same determination is justified for biomass boilers. The severe economic impact on forest products and other industries that operate biomass boilers will be a disincentive to continue to operate or expand the use of biomass boilers. This is contrary to environmental and energy policies established by the state and federal government which promote the use of biomass boilers. It's good policy because dioxin/furan emissions are typically lower, there is no net increase in greenhouse gas emissions, and there is an abundance of biomass which is a renewable, domestic energy source.

Response: Refer to DCN EPA-HQ-OAR-2002-0058-2906.1, excerpt 5 for a response the request for work practices not emission limits. Refer to DCN EPA-HQ-OAR-2002-0058-2882.1, excerpt 7 for a response the cost impact to the forest products industry.

Comment: MSU has collected some CO data on their PC boilers in July and August 2010 using portable equipment. This data is currently being reviewed for correctness and will be available in September.

MSU, along with the University of Purdue and the Pennsylvania State University, met with EPA's Robert Wayland and his staff on July 16, 2010. Part of this discussion involved concerns with achieving CO limits at all operating loads. As part of our commitment to Mr. Wayland during this meeting, we have attached hourly CO ppm CEMS data for MSU's CFB boiler. This data is contained in three Attachments. The attachments include 12 months of our CFB operating history. MSU can supply the data from the PC boilers in September. [See DCN:EPA-HQ-OAR-2002-0058-2816.2 through DCN:EPA-HQ-OAR-2002-0058-2816.4 for attachments]

Response: This data has been entered into the EPA database.

Comment: EPA should adopt a limited use category and exemptions (e.g. no limitations, no continuous emissions monitoring, etc.) for startup boilers, that provide steam to assist in the start-up of electric generating units. APPA members have noted that the map of major source boiler locations provided on EPA's web site for the proposed rule at http://www.epa.gov/airquality/combustion/actions.html does not show start-up boilers that could be subject to the proposed rule. This suggests that EPA may have not accounted for start-up boilers in developing the rule's cost and emissions performance criteria (e.g boilers from which the best performing 12% of could be determined), and therefore the proposed emissions limitations may be deficient because they are based on incomplete data.

Comment: NHDES is concerned about the limited data used for setting the emission limitations in the area and major source regulations. In the case of data availability, NHDES recommends that EPA utilize certified stack test data submitted by the states via the National Association of Clean Air Agencies (NACAA) to develop a more robust data set when developing emission limits.
NHDES suggests that EPA use all available certified data along with appropriate subcategories to develop accurate emission limitations that will result in actual HAP emission reductions while taking into consideration the effect these limits will have on emissions of other pollutants

Comment: To grant this request for an alternate limit for THC, EPA needs to gather additional THC data. However, there is some data available in the record to begin this analysis. For PC boilers, EPA obtained 30 days of THC and CO CEMS data from a Phillip Morris unit in Virginia. This data is displayed in Figure 16. The Upper Predicted Level at a 99 percent confidence interval for this data is 6 ppm (@3 percent O2) excluding the three startup periods and 18 ppm including the startup periods. For stoker boilers, EPA obtained 30 days of THC and CO CEMS data from a DuPont unit in West Virginia. This data is displayed in Figure 17. However, this boiler never ran below 50 percent load and no startups were included in the data, so this data really cannot be used to set an appropriate standard. Eastman proposes that EPA include the use of THC in lieu of CO , and that EPA collect additional data to establish a reasonable standard that reflects both steady-state and SSM operation. Eastman would be willing to collect such data to promote sound data-based decision making.

Comment Excerpt Number: 20

Comment: EPA's floors for ICIBPH are based on some of the data available to the Agency via information collection requests, undertaken both in support of this rulemaking (undertaken in 2007-2009) and in support of the Agency's previous (and now vacated) 2004 rules for this industrial category. However, EPA has arbitrarily refused to consider actual emissions data for major source boilers gathered by the National Association of Clean Air Agencies (NACAA). As the agency itself has stated, "EPA must consider available emissions information to determine the MACT floors." 75 Fed. Reg. at 32019 (emphasis added). Because the NACAA data is "available" to EPA, the agency must consider it in setting floors.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2841.1, Excerpt Number 9.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 21

Comment: EPA should use the data submitted with these comments to include the variability for this boiler.

Response: The provided data is not in a format suitable for inclusion in the rulemaking efforts.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 22

Comment: While none of Eastman's units were identified as top performers for mercury, we have included Figures 7 and 8 to show how our coal supply varies. Also, to assist with further statistical analysis, we have included both mercury and chlorine data from two of our powerhouses [See Excel file on CD submitted to the docket] which illustrates the variability over a five year period of time.

Response: The provided data is not in a format suitable for inclusion in the rulemaking efforts.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 24

Comment: EPA needs to do is collect coal chlorine data and mercury either directly from the sources (as Eastman is providing today) or from the suppliers that serve the top performers. If units do not have a large data set such as Eastman's, then EPA should collect chlorine data available from the coal suppliers.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2841.1, Excerpt Number 9.

Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 42

Comment: To add to the record that startups and shutdowns do have a significant impact on 30 day average CO emission levels, Eastman is submitting data from a CO CEMS on one of our stoker boilers. First, in Figure 3 of the submittal, we include data from a startup period for this boiler that shows the significant CO emissions incurred. As shown, the CO CEMS is actually out of span during part of this period. This adds to the argument that 30 day averages should exclude periods of startup and shutdown.

Response: The provided data is not in a format suitable for inclusion in the rulemaking efforts.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 43

Comment: We have included Figure 11 of the submittal which shows 10 months of data from another of our stoker boilers. This graph clearly shows the impact of startups on a 30 day rolling average CO emission.

Response: The provided data is not in a format suitable for inclusion in the rulemaking efforts.

Comment Excerpt Number: 6

Comment: The proposed MACT Standards did not take into account California's long history of comprehensive toxics control programs. ARB's statewide air toxics program was established in the 1983 under the Toxic Air Contaminant Identification and Control Act (AB 1807, Tanner) which created California's program to reduce exposure to air toxics. The Air Toxics "Hot Spots" Information and Assessment Act (AB 2588, Connelly 1987) supplemented the AB 1807 program, by requiring a statewide air toxics inventory as well as notification of people exposed to a significant health risk. Facilities that are found to pose a significant health risk to the community are required to reduce their risk below the level of significance through a risk management plan. All HAPs identified by U.S. EPA are included in California's list of toxic air contaminants (TAC) and additional chemicals have also been added to the list by ARB, based on toxicity and potential exposure. Over 600 substances have been listed under the Act.

In addition, districts include a TAC review during the permitting process for new and modified facilities. Sources emitting TACs must comply with district requirements regarding risk assessment and risk management of TAC emissions. Screening analyses and health risk assessments are performed as part of the permitting process. In the case of unacceptable health risks, districts require mitigation to reduce the risk.

Since the goal of U.S. EPA in developing any MACT standard is to reduce public exposure to hazardous air pollutants, any analysis conducted should include consideration of existing state programs that accomplish or contribute to the same goal.

Comment Excerpt Number: 2

Comment: Under the IQA, EPA's determination must be accurate, reliable and unbiased, and must be presented objectively. The IQA requires that all agency documents disseminated to the public must meet "a basic standard of quality," defined in terms of objectivity, utility and integrity. On its face, the Boiler MACT rule fails to meet the IQA's basic standard of quality. EPA's selection of the "best of the best" as the MACT floor suggests an obvious lack of objectivity. Failure to account for 50 to, in some cases, almost 90 percent of the sources in a subcategory when setting a MACT floor suggests an equally obvious lack of accuracy. These comments constitute a formal request for correction of the Boiler MACT data deficiencies as provided for in the IQA.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Comment Excerpt Number: 3

Comment: AMP and the City of Painesville ask that EPA allow time after the close of the comment period for the submission of data from stack testing currently underway on HCI emissions from the Painesville stoker units so that the data can be quality assured and quality controlled prior to submission. Given the small amount of data available, we encourage EPA to incorporate these new data into the MACT floor analysis as the best available information for stoker emissions rates. Public Comments (Dec. 2, 2008).

Response: EPA did not receive the additional HCl test data from this facility. In the final rule, we considered data submitted up until November 17, 2010, which was the latest allowable date to consider new data given the regulatory development process and current rule schedule.

Commenter Name: Catharine Fitzsimons
Commenter Affiliation: Iowa Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-2767.1
Comment Excerpt Number: 5

Comment: EPA acknowledged that it did not use any of the emission test reports compiled from state and local program files that NACAA provided to EPA in the summer of 2008. Instead, it appears that EPA based its calculations on a "new" data set that incorporates data collected by facilities. IDNR is not commenting on whether EPA should or should not have used the emissions data provided by NACAA in 2008. However, IDNR does agree with NACAA that EPA has not provided a sufficient explanation for why EPA did not include any of the emission data provided by NACAA. EPA has an obligation under the CAA to consider all emissions data. Given the limited number of sources that EPA evaluated in each source category, it is particularly important that EPA consider all emission data available, and provide a reasonable explanation for why it chooses to exclude such data from its analysis.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2841.1, Excerpt Number 9.

Comment: While CO CEMS data is not available for the 1998 period when the stack test occurred, current CEMS data indicate that the boilers operate on a higher average CO concentration (see Attachment 1 for CEMS operating data for the first four months of 2010).

Response: This data has been entered into the EPA database.

Commenter Name: Michael Potter
Commenter Affiliation: Goodyear Tire and Rubber Company
Document Control Number: EPA-HQ-OAR-2002-0058-3181
Comment Excerpt Number: 5

Comment: EPA's cost estimates are inadequate.

Although the comment period did not provide enough time to conduct a thorough review of EPA's database, it appears that only three of Goodyear's boilers with oil-firing capability, located at only one plant location, were included in EPA's cost estimate database. Because only three of Goodyear's sixteen potentially regulated boilers were considered when EPA developed its cost estimate information, Goodyear expects that EPA's estimate of potential cost to Goodyear — and potentially other companies as well —is several times too low. Such a costly proposal warrants a thorough and complete cost analysis, and for that purpose, Goodyear is concerned that EPA's cost analysis may be inadequate and should be reconsidered.

Response: The additional Goodyear liquid boilers have been added to the inventory of units and will be factored into future analyses.

Commenter Affiliation: American Iron and Steel Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2998.1
Comment Excerpt Number: 9

Comment: To gain a better understanding of the potential risk faced by coke oven gas-fired units under the broad Gas 2 subcategory proposed by EPA, an AISI member company conducted stack tests on four coke oven gas-fired boilers in July 2010. The test results confirm that the proposed Gas 2 emission limits for HCl, Hg, and CO are not achievable for these coke oven gas-fired boilers using commercially available emission control technologies. The tests were performed on four identical tangentially-fired industrial boilers. Each boiler has a rated heat input capacity of 650 MMBTU/hour and fires only gaseous fuels, comprised of a mixture of coke oven gas and blast furnace gas with supplementary natural gas, that are supplied to the boilers from common headers for each fuel. Typical fuel gas analyses are provided in Table 1. [see submittal for Table 1. typical process gas analysis.] The boilers operated at 73% to 87% (average 83%) of design heat input capacity during the tests. The average contribution of each fuel to total heat input during the tests was 50% coke oven gas, 39% blast furnace gas and 11% natural gas (Table 2) [see submittal for table 2: fuel heat input to each unit tests .]

The test program included the following measurements in each boiler stack:

Group A:

CO by EPA Method 10;

Dioxins and furans by EPA Method 23;

HCl and filterable non-sulfuric acid PM by EPA Method 26A, combined with EPA Method 5B;

Group B:

Hg and filterable non-sulfuric acid PM by EPA Methods 29 and 101A, combined with EPA Method 5B (modified);

Stack gas flow rate by EPA Method 2 (all tests); and

Oxygen, carbon dioxide and moisture concentration by EPA Methods 3A and 4 (all tests).

Three 4-hour test runs were performed on each of the four boilers. Group A and Group B tests were not conducted simultaneously. Tests were performed at approximately the same time of day and under comparable operating conditions. The test methods for CO, Hg, HCl and dioxins/furans are among those specified by EPA for tests conducted under the ICR for this rule and in Table 5 to Subpart DDDDD of Part 63 – Performance Testing Requirements of the proposed rule. [The test method for dioxins/furans was left blank in Table 5 of the proposed rule. EPA should correct this oversight in the final rule. We assume that Method 23 is the intended method for these compounds based on the preamble discussion at 75 Fed. Reg. 32013.]

Response: The provided stack test data for the coke oven gas-fired boilers have been added to the EPA database and will be factored into future analyses.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: ArcelorMittal USA, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2811.1
Comment Excerpt Number: 15

Comment: To better understand the potential risk faced by coke oven gas-fired units under the broad Gas-2 subcategory proposed by EPA, stack tests were conducted on four coke oven gas-fired boilers during July 2010. [See submittal for Appendix A: Draft Test Results.] The test results confirm that the proposed Gas-2 emission limits for HC1, mercury and CO are not achievable for these coke oven gas-fired boilers using commercially available emission control technologies. The tests were performed on four identical tangentially-fired industrial boilers. Each boiler has a rated heat input capacity of 650 MMBM/hr and fires only gas fuels, comprised of a mixture of coke oven gas and blast furnace gas with supplementary natural gas, that are supplied to the boilers from common headers for each fuel. Typical fuel gas analyses are provided in the submitted Table 1. The boilers operated at 73% to 87% (average 83%) of design heat input capacity during the tests. The average contribution of each fuel to total heat input during the tests was 50% coke oven gas, 39% blast furnace gas and 11% natural gas (See the submittal for Table 2).

The test program was conducted in two groups and included the following measurements in each boiler stack:

Group A:
Carbon monoxide by EPA Method 10;
Dioxins and furans by EPA Method 23;
Hydrogen chloride and filterable non-sulfuric acid particulate matter by EPA Method 26A, combined with EPA Method 5B;
Group B:
Mercury and filterable non-sulfuric acid particulate matter by EPA Methods 29 and 101A, combined with EPA Method 5B (modified);
Stack gas flow rate by EPA Method 2 (all tests); and

Oxygen, carbon dioxide and moisture concentration by EPA Methods 3A and 4 (all tests).

Three 4-hour test runs were performed on each of the four boilers. Group A and Group B tests were not conducted simultaneously. Tests were performed at approximately the same time of day and under comparable operating conditions. The test methods for CO, mercury, HC1 and dioxins/furans were among those specified by EPA for tests conducted under the Information Collection Request for this rule and in Table 5 to Subpart DDDDD of Part 63 — Performance Testing Requirements of the proposed rule. [Footnote: The test method for dioxins/furans was left blank in Table 5 of the proposed rule. EPA should correct this oversight in the final rule. We assume that Method 23 is the intended method for these compounds based on the preamble discussion at 75 Fed. Reg. 32013.]

Method 5B was selected for filterable particulate matter because it is believed to be a superior surrogate for non-mercury metallic HAPs when sulfuric acid may be present, as discussed in Section III of these comments below. SO2 concentrations in the exhaust gas indicate that sulfuric acid may be present at concentrations on the order of 5-7 ppmv, which represents a potentially large fraction of the proposed filterable particulate emission limit (on a lb/MMBtu basis). Method 5B is designed to mitigate the effect of sulfuric acid on the filterable particulate matter results, which allows for a more accurate surrogate for non-mercury metallic HAP. For the Method 29 and Method 101A tests, filterable particulate matter samples were collected with the probe and filter temperature at 160 °C as specified in Method 5B, but the laboratory analysis was modified by drying the samples in a desiccator at room temperature as specified in Methods 29 and 101A rather than in an oven at 160 °C as specified in Method 5B, so that mercury was preserved in these samples. For the Method 26A tests, Method 5B was performed normally.

The test results show highly variable CO emissions with an average concentration 28 times higher than the proposed limit. Also, HC1 and mercury exceed the proposed limits by more than an order of magnitude (Table 3 and Figure 1) rendering them unachievable. Highly variable CO results among the four identical units were not unexpected due to the presence of blast furnace gas in the fuel mix. [Footnote: Blast Furnace Gas contains large amounts of carbon monoxide and no organic HAP, thus the presence of CO in the exhaust gas from BFG fuel mixtures may not be an indication of the presence of organic HAP. The highest CO was observed during tests on Boiler 12, which is attributed to the higher relative contribution of blast furnace gas at that boiler.] the nature of these low Btu fuels, and normal variations in boiler operations even at a relatively constant total heat input near design capacity. These short duration tests cannot capture the full range of normal operating conditions that might be experienced over several years. However, they are important indications that COG-fired units are significantly different from other Gas-2 units and that further data and analysis are needed before EPA can establish non-arbitrary numeric emission limits for COG-fired units.

The levels of HC1, mercury and CO exceed the proposed Gas-2 limits by such a large margin that available emission control measures would be insufficient to achieve the proposed Gas-2 limits. If optimistic assumptions for control efficiency are applied to the uncontrolled levels measured in these tests, it is clear that the Gas-2 emission limits cannot be reliably achieved (Table 4). Even assuming 99% HC1 removal (which is overly optimistic given the low inlet HC1 concentrations and challenges associated with optimizing scrubber performance when burning variable mixed gas fuels), the proposed Gas-2 limits could not be achieved. While activated carbon injection has been reported to effectively reduce mercury emissions between 70 and 90+% at the much higher inlet mercury concentrations present in waste incinerators and coal-fired boilers, such efforts will be less effective for the very low inlet concentrations found in coke oven gas-fired boilers. Optimistically assuming 80% control efficiency, controlled mercury levels will be 5 to 10 times higher than the proposed Gas-2 limits. CO reduction efficiency by oxidation catalysts is reported to be effective in gas turbine applications; however, boiler stack gas temperatures are much lower than catalyst temperatures in those applications, and oxidation catalyst efficiency decreases with decreasing temperature. Even assuming a (likely unrealistic) CO reduction efficiency of 90%, it would not be possible to achieve or reliably detect the post-control results the Gas-2 emission limits in 3 of the 4 cases.

Response: The provided stack test data for the coke oven gas-fired boilers have been added to the EPA database and will be factored into future analyses.

Comment: EPA has listed several GP boilers in the MACT floor and must include other test data for these units
To calculate the MACT floor, EPA identified best performers from the lowest reported test of these units and also included other test results from these units in the calculation. The Memo (and underlying data base) list several GP units as being best performers and EPA includes them in calculation of the MACT floor. GP has other test results from these EPA-identified units that should also be included in its database. The submittal includes Table 13a shows the by-run test results from these tests. The full test reports will be made available to the Agency upon request. As noted in the comments field, some of the tests in Table 13a were conducted using a single ESP field or low voltage on the ESP or at unusually high or low steam loads. These conditions were run to simulate operation under upset conditions during normal operation when a malfunction of the ESP occurs. Because these types of upsets do occur, even at the best performing units, EPA must include these data in its floor analysis.

Response: This data has been entered into the EPA database.

Comment: EPA has collected significant data over the past several
months. It has worked to make that data available for
review. As the public has reviewed this data it is
clear that EPA needs to perform additional quality
assurance to ensure that the data is accurate. Data
review has found inconsistent treatment of non-detect

values, improper classification of boilers, and gaps in
data that could be improved with additional quality
assurance. MeadWestvaco believes that this step is
crucial before EPA can realistically propose such
standards.

Comment: We believe the estimate of the number of boiler and process heaters impacted by this proposal is significantly understated. We note for instance that the proposal for the vacated Boiler and Process Heater NESHAP estimated at 68 FR 1687 (January 13, 2003) that there would be a total of 58,200 affected existing units versus the current estimate of 13,555, suggesting an under-counting by more than a factor of 4. That original estimate was based on input from a vast number of sources during the Industrial Combustion Coordinated Rulemaking (ICCR) effort. Similarly, the 2003 proposal estimated 3463 new units per year rather than the 46 units per year estimated here. The RIA for that rulemaking [Footnote: EPA-452/R-04-002 (February 2004)] details the development of their estimate in Section 3.

Comment: U.S. EPA database at facilities with boilers and process heaters is significantly in error and fails to list numerous facilities.
For example, in Wilmington you left out Tesoro Oil Refinery, Valero Oil Refinery, Ultramar Special Products Refinery, which is an asphalt facility, and the Valero Wilmington Asphalt Plant. In the city of Carson, which is not in the database, is the BP Arco Oil Refinery, the ConocoPhillips Asphalt Specialty Products Facility, the Equilon Enterprises Asphalt Facility and the Tesoro Refinery Marketing Salt Recovery Facility.
In the city of El Segundo you left out the Chevron Oil Refinery. In the City of Long Beach at the Port of Long Beach you left out an incinerator facility, which I don't know the name of but it's there.
To give you a quick reference, you can see by this map that was put together by the California Air Resources Board. Going back in 2005, Wilmington was part of a study to identify toxic sources.
This one right here shows you different little dots that identify the various toxic sources.
And what I'm referring to here is that Wilmington is a poster child for having the most significant human impact resources in one community. The next step that we were supposed to do was a follow-up in doing a ground trooping that had anything else that was missing, but ARB has not continued the project since that time, and so we only have achieved up to this point -- and I will be submitting a copy of this map in a smaller volume and a digital format so that you do have it.
We request that the U.S. EPA validate its boiler and heater facility list with state regulatory

agencies such as CAL-EPA, California Air Resources Board and our local HMDs and, in our particular case, South Coast Air Quality Management District.
If the U.S. EPA boiler facility list is off by at least ten major facilities in Wilmington, that means the total emissions inventory is also significantly underestimated by at least ten times. And if the emissions inventory is estimated by at least ten times, that means our health impact assessment and the numbers that are coded are also underestimated at least by ten times in our community.

Response: EPA has updated its inventory based on comments received during the public comment period. Among the refineries listed by the commenter, the following were added to the database: In Wilmington, CA, the Tesoro and Valero oil refineries were added. In Carson, CA, the BP Arco oil refinery and ConocoPhillips Asphalt Specialty Products facility were added. The Chevron oil refinery in El Segundo, CA, was added. The remaining facilities listed were not added to the database due to the inability to obtain information on their applicable combustion units.

Comment: I am concerned that your list of toxic facilities with boilers or incinerators is not accurate and complete. Your list doesn't include BP-Arco Oil Refinery. It also doesn't include specialty product oil refineries such as:
A) ConocoPhillips Company, Carson Refinery.
B) Equilon Enterprises, LLC, Shell Oil Products U.S.A. Desoto (phonetic) Refinery and Marketing Company, a sulphur recovery plant. Specialty products include sulphur recovery facilities and asphalt refineries.
Point two, as a result, your boiler toxic emissions are significantly underestimated in my environmental justice community of Carson.
Point three, therefore your public health risk assessment is also significantly underestimated and must be updated and a monitoring system must be implemented.

Response: See response for DCN EPA-HQ-OAR-2002-0058-1778, Excerpt Number 75.

Comment: The carbon monoxide (CO) limits are unreasonably low -for several reasons:

According to manufacturers of calibration standards for reference materials traceable through the National Institute of Standards and Technology (NIST), the lowest concentration for CO reference material available is 5 parts per million (ppm). Based on testing procedures established by EPA through 40 CFR 60, Appendix B and Appendix F, a calibration curve should include concentrations of 30%, 50% and 80% of span. In this case, 5 ppm would represent the lowest calibration concentration point, or 30% of span. This requires that the span be set at 15 ppm. Also according to EPA's own reference methods, the span is determined as a factor (1.5 to 2) of the standard. Therefore, based on the criteria established by EPA's own reference methods, the lowest emission limit measureable that meets the calibration criteria of EPA's reference methods is between 7.5 and 10 ppm.

The test results used to determine the MACT floor should be reviewed with respect to the integrity of the calibration procedures noted in the above paragraph. EPA should throw out any of the results whose calibration procedure did not conform to the calibration criteria of the methods.

Also based on the calibration criteria of the reference methods cited above, the "zero" calibration point is acceptable if the concentration of CO is less than 1 ppm. This means that "zero" could be as high as 1 ppm. EPA is proposing emission limits that are essentially zero as a practical matter. For the data set used to determine the MACT floor, EPA should reject those results that are statistically equal to zero.

Response: EPA has made corrections to very low reported CO values, see the preamble for how EPA adjusted the CO values to consider measurement error.

Comment: The emissions database includes numerous fundamental flaws that compromise the MACT floor analysis that is based on these data.
Given the limited comment period that has been provided on the Industrial Boiler MACT proposal, it simply has not been possible to conduct a thorough data quality assessment on EPA's entire emissions data base. EPA's failure to provide adequate time for an appropriate assessment of the data violates the Agency's obligation to provide a full and fair opportunity for public comment on the proposed rule. Within these severe time constraints, we conducted a spot check of 100 stack test reports and associated information from top performers in order to assess the quality of the data the Agency relied upon in calculating the MACT floors that underlie the proposed rule.

This spot check revealed numerous data errors – many of which, if corrected, would have a material impact on the stringency of EPA's calculated MACT floors and associated proposed standards. To name just a few, there was: (1) widespread inconsistency in the data reported under the Phase I and Phase II ICRs, such as entirely different methods of determining and reporting "non detects"; (2) inconsistent reporting of dioxin/furan emissions testing results; (3) inconsistent and incompatible PM emissions testing methods; and (4) mischaracterization of boiler types, such as including a coal-fired boiler in the biomass subcategory. The number and magnitude of the errors provide clear evidence that the database is fundamentally flawed and that any standard derived from the database does not have adequate factual support.

To resolve this problem, EPA must conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for public comments (including sufficient time for commenters to conduct their own comprehensive review of the data).

Comment: EPA has failed to conduct a detailed review of the IB emissions data. EPA has rushed to issue a proposed rule to comply with an aggressive rulemaking schedule that EPA should never have agreed to in a consent decree. EPA does not appear to have conducted an independent quality assurance review of the data IBs submitted in response to an extensive information collection request ("ICR"). Other commenters provide numerous examples of errors in the information EPA used to identify the best performing units and to set MACT floors. EPA must conduct a thorough review of all IB emissions data before proposing MACT standards. If more time is needed to complete the MACT rulemaking, then EPA should request that time from the court.

Comment Excerpt Number: 5

Comment: Dioxin data error needs to be corrected in Phase II ICR Database

The data included in EPA's database for dioxin emissions from Purdue's Boiler #5 (a unit tested as part of the Phase II ICR), is listed in the database incorrectly. The error in the data entry resulted in Boiler #5 being listed as one of the two top performers in the dioxin category by several orders of magnitude. The corrected data is attached. Purdue understands that the data for the other top performer for dioxin in a CFB with bituminous coal is also in error. Purdue expects that EPA will adjust the floor determination accordingly.

Response: The specified data corrections have been processed in the EPA database.

Comment: While we support EPA using all available resources to ensure full representation of the sector or subcategory, several floors proposed in this rule include data not acquired through the recent Information Collection Request (ICR). These instances are often in categories with very few data points, potentially magnifying any errors or unrepresentative situations, such as the inclusion of jet fuel in the liquid-fired category, discussed below. At a minimum, EPA should release all data included in addition to or in place of ICR data, along with their detailed test reports, to ensure full public review of any data used to establish a MACT floor.

Comment Excerpt Number: 8

Comment: Correct emissions test data for Alcoa's Warrick power plant were submitted to EPA through the ERT. However, EPA's Access database contains erroneous emissions data for Unit 3 (all test runs and all pollutants). Also, the database reports emissions for Unit 2 even though Unit 2 was not tested as part of the §114 test request. The database needs to be corrected and any emission standards should that used the Warrick power plant data should be revised accordingly.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: G. Vinson Hellwig and Robert H. Colby
Commenter Affiliation: National Assocation of Clean Air Agencies
Document Control Number: EPA-HQ-OAR-2002-0058-2841.1
Comment Excerpt Number: 9

Comment: EPA acknowledges that it did not use any of the emission test reports in state and local permit authority files and provided to it in the summer of 2008 (in the NACAA Model Rule database) in establishing its proposed MACT floors.[NACAA has formally resubmitted this data to the dockets in these rulemakings.] Instead, EPA based its calculations entirely on its "new" data set that incorporates data collected by emission sources. We believe this is a clear error that will jeopardize the final rule. We acknowledge that the subsequently collected data fills gaps that existed in the NACAA data set and do not object to EPA's use of this additional information. Incorporation of these test results in EPA's MACT floor calculations is not likely to change the calculated floor for many subcategories, but, especially considering the proposed adoption of many small subcategories, this cannot be known or assumed to be true. Exclusion of reference test results merely because they were maintained in the files of the regulatory authorities rather than those subject to regulation is arbitrary.

NACAA believes that its data set is more objective than the subsequent industry testing, since the NACAA testing was often supervised by state or local inspectors and was conducted without knowledge by the source (or the permitting authority) that the data would be used in developing emission limitations. In contrast, testing conducted as part of EPA's more recent information-gathering activities was almost universally conducted by sources who understood that it was in their interest to obtain high emission levels during the testing and was conducted without oversight by federal, state or local authorities. The regulated community was allowed to define the operating parameters for the tests.[We do not assert that there was widespread "gaming" by industry, only that there is no reason to believe that the more recent data is more credible than the information submitted by NACAA. We do note that the Office of Management and Budget (OMB) was extensively involved in the development of the test plan and that NACAA's comments respecting the test plan were largely ignored by EPA and OMB, while industry requests were accommodated. NACAA hereby incorporates its comments to EPA and OMB on the proposed testing in this comment and the administrative record in this matter] More importantly, the EPA data includes numerous entries where a source was combusting different fuel mixes, which NACAA believes will be difficult to translate into enforceable MACT limitations. While NACAA and EPA data sets often produce generally consistent results, EPA is not free to exclude from the calculation of the top performing 12 percent testing conducted for other compliance purposes as required by state and local permit officials. EPA has asserted that it does not need to consider the information provided to it by NACAA since industry sources "should" have provided this information. This assumption has not been shown to be correct and is insufficient given EPA's obligation to consider all emissions data and the relative ease of determining whether there are any NACAA-provided test results that should be included in the evaluation of the top 12 percent of performing units or any variability analyses that are conducted.

NACAA does not assert that the MACT floor calculations should be based on the data it provided to EPA in lieu of that subsequently collected by EPA, just that EPA must consider all of the emissions data available to it and not ignore the NACAA-provided information. Indeed, the EPA data fills significant gaps in needed knowledge of mercury, HCl and dioxin/furan information.

Response: In addition to the testing mentioned by the commenter, EPA conducted a comprehensive survey under an Information Collection Request. In the directions to this survey, EPA requested sources to submit the results of the most recent stack test data for each of the pollutants listed in the emission test spreadsheet by completing the spreadsheet linked below. EPA also accepted other supporting emission test data to document any earlier emission tests on the unit with similar controls and fuels as well as tests available relative to trials or tests of emission control methods or R&D efforts. The limit for requesting these tests was that the test had to reflect current operating conditions. This limit was introduced to prevent the use of older test data from units that are no longer relevant. The NACAA database does not incorporate this limit on the data so it could include CO tests on units that have since installed NOx equipment or other controls to comply with the vacated standard. It also contains many duplicates to the data reported to the ICR survey that could not be fleshed out and identified within the labeling of the units in the NACAA database. EPA has updated the initial inventory based its ICR survey data to incorporate specific comments and corrections and the current inventory of boilers resulting from the ICR supersedes previous inventories.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group
Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 12

Comment: The Auto Group also has significant doubts as to whether EPA has performed a thorough Quality Assurance/Quality Control (QA/QC) review of the database itself. The background document in the docket providing EPA's floor analyses for the potential Gas 1 floors in the preamble indicates that EPA included in its analysis direct-fired process heaters, which are not supposed to be included in the rule. Specifically, EPA included a direct-fired rod/bar mill furnace (CORockyMtnSteel212) among the natural gas-fired units comprising the floors for hydrogen chloride (HCl), carbon monoxide (CO), and dioxins/furans (D/F). [Footnote: See Memorandum from A. Singelton, ERG, to J. Eddinger, U.S. EPA, MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 143, 168, 186 (April 2010).] According to the owner and operator of the Rocky Mountain Steel unit, the unit is a direct-fired re-heat furnace where steel billet intermediate product comes into direct contact with the products of combustion. This explains why the test data for the unit shows such low CO and D/F levels. Such database errors call into question whether EPA has included the correct units in the database used to set the MACT floors in the proposal and whether EPA has undertaken the necessary QA/QC of the database.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 12

Comment: Significant errors exist in the database used to set CO limits for coal-fired boilers.

While we do not believe MACT standards should be set for CO based on stack test data alone (see more comments below), we believe there are significant errors in EPA's database that need correction.

For the PC boiler subcategory, EPA has made translation errors with the data for the top three performers it identified. Specifically, for the three boilers at the ILDukeEnergyTuscola facility, Units 1, 3, and 4, Appendix C-3 to the MACT floor memo shows the best stack results as 0.053 ppm CO for Unit 3, 0.0553 ppm CO for Unit 4, and 0.0571 ppm CO for Unit 1. All these values were derived from the EPA' Access database that has the reported data expressed as ppb instead of ppm. This error needs correction and the MACT floor analyses for new and existing units should be redone.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Jack Carter
Commenter Affiliation: Weyerhaeuser Company
Document Control Number: EPA-HQ-OAR-2002-0058-2797.1
Comment Excerpt Number: 30

Comment: Four Weyerhaeuser wood products mills were selected to participate in the "Phase 2" stack testing portion of EPA's Information Collection Request survey implemented under the CAA §114. Upon review of EPA's final database a number of errors have been identified in the test report data submitted to EPA for three of the sites. The fourth site is no longer in Weyerhaeuser ownership, and we understand the boiler is not in operation by the new owner. Corrections to these data and a limited set of "Phase 1" data have been submitted to EPA (to the attention of Mr. Brian Shrager, USEPA, and to EPA's data contractor, ERG, at its website). [See submittal for Exhibit 1 showing an email specifying corrections to facility emissions data.]. Copies of the submitted corrections are included as an attachment to these comments so that they are included in the docket.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group
Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 30

Comment: Work practices are More Appropriate for Boilers/Process Heaters Using Landfill Gas and Fit with the Criteria for Section 112(h) Work Practices.

Despite the fact that three of EPA's five proposed HAP floors (particulate matter (PM), mercury (Hg), and D/F) for the Gas 2 subcategory include data from a single landfill gas unit (BMW), EPA's data for landfill gas units are not accurate and do not reflect what is achieved in practice by these sources. For example, there appears to be an error in the Hg data for the BMW unit. The error seems to result from not including the detection limits for undetected values when summing the five different analytical fractions for the Method 29 sampling train. EPA specified in the guidelines for the ICR that detection limits should be included in the data sums submitted to EPA. The lab analysis report for the BMW unit for Method 29, however, shows total mercury catches which include only the detected value in the HCl rinses. If summing detection limits with the detected values following EPA guidelines for the tests, the total mercury catches would be approximately four times higher. This would result in a much higher Hg floor for the Gas 2 subcategory. [Footnote: BMW will be submitting revised Hg information to EPA in a separate letter.]

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 48

Comment: Emission test results for filterable particulate matter, mercury, HCl, CO, and dioxin/furan are the underlying basis for the proposed emission limits. In 2008, EPA distributed a survey targeted at 'major' (with respect to hazardous air pollutants) sources. This survey was intended to gather information on individual boilers and process heaters. Respondents were also asked to submit summaries of available emission test and fuel analysis results using spreadsheets. A database was created from the spreadsheet submissions and it was used to assess the need for additional data to support the Boiler MACT rulemaking.
In 2009, a second ICR mandated extensive stack testing and fuel analyses at roughly 150 boilers and process heaters. EPA selected these units to fill perceived information gaps in the database and to obtain additional test data from numerous 'best performing' units to examine emissions variability. Companies were given only four months to conduct this testing and submit the results to EPA.
A combined Microsoft Access emissions database with the 2008 survey responses and 2009 testing program results was first released in January 2010 and then revised in February 2010, March 2010, and April 2010 ("Emissions Database for Boilers and Process Heaters Containing Stack Test, CEM, & Fuel Analysis Data Reported under ICR No. 2286.01 and ICR No. 2286.03, Version 5). Revisions were made to incorporate late-arriving results from the second ICR, delete information from units that had ceased operation, correct data that had been entered into the database from faulty output from EPA's Electronic Reporting Tool (ERT), adjust dioxin/furan test results, and correct miscellaneous reporting inconsistencies and other problems.
The file size for Version 5 of the database is about 110 MB. It contains 44,389 records with emission test results; 92,822 records with fuel analysis information; and 44,219 records with CEMS data. Although this is a massive amount of information, the emissions data in the database being used to set these standards that will impact thousands of sources should be checked by EPA for accuracy.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1

Comment Excerpt Number: 49

Comment: Over the past several months, the National Council for Air and Stream Improvement (NCASI) [Footnote: The National Council for Air and Stream Improvement (NCASI) is an independent, non-profit research institute that focuses on environmental topics of interest to the forest products industry.] has examined about 100 stack test reports and associated laboratory analysis reports for filterable particulate matter, dioxin/furan, mercury, HCl, formaldehyde, and/or total hydrocarbons (THC). Most of these reports were for boilers assigned to either the biomass or coal subcategories, and most were listed in the Version 5 (or earlier versions) database as being among the units with an emission test in the lowest 12% for filterable particulate matter, dioxin/furan, mercury or HCl. NCASI found a disturbing number of problems with the test results appearing in the Version 5 database for these so-called ‘best performing’ boilers. It was obvious the test results being used to develop the proposed emission limits had not received an adequate review. Some of the problems identified by NCASI, when corrected, will have a dramatic impact on the proposed emission limits. It is imperative for EPA to thoroughly review all of the available data for the top performing units before promulgating emission limits. We identify several data quality problems that should be corrected throughout these comments, and many of our member companies have submitted requests for data corrections to EPA.
The most critical shortcoming in EPA’s data analysis is merging test results reported by 2008 survey respondents with test results from the 2009 mandatory test program into a single database that was used to identify ‘best performers’ in each subcategory and calculate emission limits. EPA implicitly assumed they were equivalent in terms of quality without conducting a detailed review of the actual stack sampling and associated laboratory analysis reports.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)
Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 54

Comment: There are many other problems in Version 5 database caused by lack of adequate review of stack sampling and associated laboratory reports. The following are examples of problems with ‘top performer’ emissions data for the biomass subcategory:
* ARGBPMorrilton – Unit SN-04 conducted stack tests in 2009 as part of the Phase II ICR. EPA’s database lists the dioxin/furan test result as being the lowest TEQ value for the biomass stoker subcategory. Individual dioxin/furan congeners are not in the database with the exception of the “total congeners” such as Total OCDD. All congeners preceded by numbers are absent from this boiler’s dioxin/furan dataset. Since the total TEQ is based on the sum of the individual congener TEQs, the total used for ranking this boiler is incorrect.

* WAWeyerhaeuser_Raymond – Hog Fuel Boiler EU-1 conducted stack tests in 2009 as part of the Phase II ICR. EPA’s database lists the dioxin/furan test as being the lowest TEQ value for the biomass fuel cell subcategory. For this boiler, “total” congener data are entered as “other.”

Further only three congeners preceded by numbers are provided in the database. The boiler owner may have submitted mislabeled data to EPA, but EPA should be able to construct a relatively simple query to find instances of this problem.

* ORWeyerhaeuserCoWarrentonLumberMill – Boiler 3-HFB conducted stack tests in 2009 as part of the Phase II ICR. EPA’s database lists the dioxin/furan test as being the third lowest TEQ value for the biomass fuel cell subcategory. Three dioxin/furan sample runs were conducted. Sample runs 1 and 3 failed almost all the quality assurance criteria. These two runs do not appear in the database. Run 2 also had very poor quality assurance values but did contain some ‘passes.’ EPA put the congeners that passed the QA into the database. Since not all congeners were entered, the sum of the TEQs is biased low (based on an incomplete dataset). Neither the testing contractor nor the lab that analyzed the samples were able to determine the cause of extremely low recoveries that resulted in two failed runs and one run with extremely poor quality results. Given the uncertainty about these tests, EPA should not include any of the results from these tests in its database.

* ARWeyerhaeuserDierksMill – Boiler SN-45 conducted stack tests in 2009 as part of the Phase II ICR. EPA’s database lists the dioxin/furan test as being the fourth lowest TEQ value for the biomass fuel cell subcategory. In the EPA database, the congener “1,2,3,7,8 PeCDD” has duplicate values for both Sample Run #2 and Sample Run #3, the congener “1,2,3,7,8,9 HxCDF” has duplicate values for both Sample Run #1 and Sample Run #2, and there are 11 other congeners that have duplicate Sample Run #2 data.

* GAGPCelluloseBrunswick, U700-No. 4 Power Boiler - This boiler is ranked No. 1 in EPA’s list of best performers for filterable PM emissions for the biomass subcategory. Data from two separate testing events for this source are in EPA’s boiler MACT database – a Phase I test conducted in November of 2007 and a Phase II test conducted in August of 2009. The Phase II data are based on EPA’s OTM 27 particulate method for measurement of filterable PM10 and PM2.5. Given that EPA Method 5 was specified as the method to use for measurement of filterable PM within EPA’s test plan for Phase II boiler MACT testing, and that OTM 27 uses an in-stack unheated filter versus Method 5’s heated out of stack filter, and that NSPS performance standards for filterable PM are based on EPA Method 5, it is inappropriate to use the filterable PM data from the OTM 27 test results. EPA Method 5 results were included in the Phase II report and should be used instead. EPA’s database lists filterable PM emissions of 0.0002, 0.0009, and 0.0005 lb/MMBtu for the OTM 27 runs one through three, respectively. This is in contrast to the Method 5 results in the same report of 0.0070, 0.0075, and 0.0035 lb/MMBtu for runs one through three, respectively.

* ORGeorgiaPacificWaunaMill, EU35-Fluidized Bed Boiler – This boiler is ranked No. 2 in EPA’s list of best performers for filterable PM emissions in the biomass subcategory. Data from two separate testing events for this source are in the Version 5 database – a Phase I test conducted in March of 2006 and a Phase II test conducted in July of 2009. Data from the Phase I test are based on Oregon’s particulate matter method ODEQ5. The Phase II data are based on EPA’s OTM 27 particulate method for measurement of filterable PM10 and PM2.5. For the same reasons stated earlier, it is inappropriate to use filterable PM data generated using OTM 27 for establishing boiler MACT floors.

* WAGraysHarborPaper, No. 6 Boiler (EU2) – This boiler is ranked No. 12 in EPA's list of best performers for HCl in the biomass subcategory on the basis of a 2009 stack test. However, EPA did not recognize that two stacks were tested and that the total boiler emissions should be the sum of the two tests. Approximately 80% of the boiler flue gas is directed to only a multiclone, and 20% is directed to a secondary multiclone followed by a packed bed venturi scrubber. These gas streams are later sent to a stack which also services another biomass boiler (EU1). The EPA database treats these as two separate tests, with the one on the venturi scrubber being much lower (0.0002 versus 0.025 lb/106Btu). A 2006 test is also in the EPA database, with an average of 0.045 lb/106Btu. This test appears to include both portions of the flue gas.

* LAGPPortHudson, EQT0109-No.6 CFB Boiler – This boiler is listed as a top performer in the biomass subcategory for filterable PM on the basis of a 2007 test with only two runs. This boiler should not be in the biomass subcategory since it was burning petroleum coke at the time of the test. In the Phase I survey, the emission test template drop-down fuel menu does not list petroleum coke, which could be the source of confusion. Because the 2007 test report was not reviewed by EPA, this discrepancy was not detected and it was assumed coke oven gas was the correct entry.

* MTPlumCreek, Wellons Plywood – This unit is listed as a top performer for HCl in the biomass subcategory on the basis of a 2009 test. The Wellons Plywood unit combusts biomass and the flue gas from the burners is directed to a plywood veneer dryer. An ESP follows the dryer, and the stack test was conducted at the ESP exit. It seems that this unit is neither a boiler or process heater (as defined in the proposed rule), since the flue gases come into direct contact with the material being dried. It appears this unit was initially mischaracterized and then mistakenly selected for Phase II sampling. A review of the stack sampling report would have uncovered this problem, but apparently the source description section of the report was not examined. All data for this unit should be removed from the EPA Boiler MACT database.

* GATempleInlandThomson, BW-B001. This unit has the lowest EPA Method 10 test for CO in the biomass stoker subcategory and thus CO test data for this unit are the basis for the new source limit for stokers, and are part of the MACT floor pool for existing biomass stokers. The Version 5 database lists BW-B001 as "Stoker/Sloped Grate/Other". The January 2009 Phase I survey database indicates a "True" in the columns labeled watertube, package, and wall-fired in the Unit Design/Operation table; all other columns pertaining to the BW-B001 description are "False". There is an obvious inconsistency between the two databases. Contacts with company personnel indicate the boiler is designed to fire sanderdust, natural gas, and distillate oil, and should be classified as a suspension burner.

The above examples are limited to the EPA-identified "top performers" in the biomass subcategory. Once EPA conducts its reviews of the reports for these units and revises its emission database, many will no longer be "top performers". They will be replaced by other units, and EPA will need to carry out reviews of additional reports to insure the quality of data being used to set the emission limits.

Response: The specified data corrections have been processed in the EPA database.

Comment Excerpt Number: 55

Comment: The following are a few issues identified in Version 5 database with some of the EPA-selected top performers in the coal and liquid subcategories:
* SCSonocoHartsville – Boiler 9 - conducted stack tests in 2009 as part of the Phase II ICR. EPA's database lists the dioxin/furan test result as being the lowest TEQ value for the coal fluidized bed subcategory. Individual dioxin/furan congeners are not in the database with the exception of the "total congeners" such as Total OCDD. The TEQ is thus based only on OCDD and OCDF, and is thus approximately two orders of magnitude too low.

* SCCogenSouth – B001 Main Boiler – This unit is listed as best performer for mercury in the coal subcategory based on a 2009 test. The EPA database has front-half and back-half results for three Method 29 runs. With the exception of Run 3 back-half, all are listed as ND. There is also a total listed for each run, but the totals are not listed as ND. Furthermore, mercury fractions below laboratory minimum levels were treated as zeroes when the totals were calculated. Rather than the three run average of 0.17 lb/1012Btu, a value of <0.51 lb/1012Btu should have been reported for the 2009 test. The EPA database also contains 2003, 2005, and 2007 mercury test results for this boiler. For each of these Method 29 tests, the total mercury emissions were calculated assuming a zero value for fractions that were below the laboratory detection limits. Thus all mercury data in the EPA database must be corrected.
* MNGPDULUTH EU33 Boiler #3 is listed in the EPA database as the lowest emitting liquid fired unit for mercury emissions. An examination of the two sets of test data for this unit revealed that non-detect fractions of mercury were treated as zero, biasing the results low. The test runs were only 2 hours long for one set of test data and only 3 hours long for the other set of data. The mercury data for this unit should be reviewed and either corrected or removed from the database.
* The October 20, 2009 report for the August 24-27, 2009 testing conducted at IAADMCornProcessingCR EU-501B indicates that all fractions of mercury were not analyzed and reported, which biases the results low.
* The SCMilliken-Dewey D30 boiler firing anhydrides waste (a unique boiler in the data set that is not representative of any other liquid-fired boiler) is a top performer for several compounds in the liquid subcategory. A review of the test report for the August 2009 testing indicates that non-detects were treated as zero or half the detection limit, which does not comport with EPA's Phase 2 ICR testing guidance and biases the results low. The emissions results for this boiler should be re-calculated.
* A review of the August 28, 2007 test report for MITBSimonPowerPlant Unit 2 indicates that the lab listed high sulfur in the samples as a possible interferent to the Method 29 analysis. The lab report also does not show receipt of all sample fractions. A review of the October 15, 2009 test report (same testing firm) for IAUofIowa EP7 Boiler 11 shows the same concerns. The data in these reports should be more closely examined to determine if it is valid.

* TX Equistar Chemicals UTBLRG CO data: The values reported were the uncorrected CO concentration and the unit of measure was incorrectly picked as “ug/dscm @ 3% O2” on the survey form. The correct unit of measure selected should have been ppmv @ 3% O2. The correct test average is 3.39E+01 ppmv @ 3% O2.
* For Units 1, 3, and 4 at the ILDukeEnergyTuscola facility, Appendix C-3 to the MACT floor memo shows the best stack results as 0.053 ppm CO for Unit 3, 0.0553 ppm CO for Unit 4, and 0.0571 ppm CO for Unit 1. These values were derived from the EPA’s Access database that has the reported data expressed as ppb instead of ppm, skewing the CO floor for pulverized coal boilers too low.

* IDTASCOPaul Unit 2 is a top performer for HCl in the coal subcategory. The unit has a wet scrubber. For the June 2006 emission test, the 3 test runs averaged 3.85E-5 lb/MMBtu with all 3 values being non-detect. EPA collected no coal chloride variability data for this unit. As the values being used in the floor analysis are below detection limits, these values should be adjusted upward to reflect a measurable value. Further variability should be accounted for with coal chloride content data.

* InAlcoaWarrick Units 2 and 3 are top performers for HCl and Unit 3 is a top performer for mercury in the coal subcategory. However, only 2 test runs are included for each boiler in the floor calculations. As two test runs do not constitute a valid emissions test and do not demonstrate emissions variability sufficiently, this data should not be included in the floor calculations.

* VAINVISTAWaynesboro Unit 2-205 (V#1) Vaporizer #1: This unit is a liquid subcategory top performer for HCl. It is a No. 6 Oil fired Dowtherm® Vaporizer (process heater) with a design heat input of 43MMBtu/hr. The 2008 emission test is listed as having averaged 0.000243 lb/MMBtu. The unit is listed in the EPA database as having a fabric filter, which is not the case - it has no control. Most likely the data for this unit has been confused with the facility’s PC fired Boiler 2, which does have a fabric filter. No fuel quality data is provided for this unit. The Vaporizer 2 emission test showed HCl emissions of 0.05 lb/hr. If operated at 43MMBtu/hr heat input, that would be 0.0012 lb/MMBtu. It is likely the heat input used to calculate the listed lb/MMBtu emission rate was also confused with Boiler 2 heat input of 168MMBtu/hr during its test (the emission test spreadsheet gives steam output for the vaporizer during those tests of 166.04, 166.1, and 167.37 Mpph, which is not applicable to a vaporizer). Therefore, the reported and utilized emission rate for this unit is too low.

* ILCognisCorp Boiler 2 is ranked #2 in the liquid subcategory by EPA based on the chlorine in the fuel (this unit is also a top performer for Hg). This unit is a 1948 vintage field erected watertube boiler with a design heat input of 67.3MMBtu/hr. Both Boilers 1 and 2 at this facility fire natural gas and waste vegetable oil as fuel per the emissions test report. All fuel analyses for this company are listed as animal fats/tallow or vegetable oil. (No analyses are provided for fuel oil). Twelve liquid analyses are provided, with Cl ranging from 0.036% to 0.13%, and HHV ranging from 13,900 to 21,300 Btu/lb. EPA listed equivalent HCl emissions for that unit as 4.74E-6 lb/MMBtu; however the EPA calculation is not correct. For example, the analysis at 0.078% and 19,100 Btu/lb is shown by EPA to be 4.4E-6 lb/MMBtu, but calculation by Cl percent and Btu/lb and 36/35 for HCl/Cl MW gives 0.042 lb/MMBtu. This type of calculation

error applies to all of that unit's analyses and emission rate calculations. The correct average equivalent HCl emission rate based on the fuel analysis data and 100% emission of chloride as HCl is 0.045 lb/MMBtu. This emission rate would put this unit above all others in the database, not in the top performers. In addition, emissions test data for Boiler 1 was provided for testing conducted during the time the liquid analyses were provided indicating an HCl emission rate of 0.005542 lb/MMBtu, ranking #186 in the EPA MACT Floor list. Fuel firing during that test consisted of 80% light liquid and 20% natural gas. Thus, while natural gas co-firing would be expected to dilute the HCl emission rate leading to lower HCl emissions, even the measured emission rate is three orders of magnitude higher than the EPA listed fuel equivalent emission rate. So there are a number of problems with this unit being used as a top performer: a) Waste vegetable oil is in no way representative of all liquids fired in units subject to the rule, and certainly is not representative of fuel oils, b) the EPA determined fuel equivalent HCl emission rate is incorrect (erroneously low), and c) the reported emission data for one of the units while cofiring the waste vegetable oil with natural gas places the unit as a worst performer. This unit's data should be corrected and it should not be among the top performers in the liquid subcategory because the fuels being fired are not representative of the majority of the units in this subcategory and are not widely available.

* MEFPLEnergyWyman Unit #5 is listed as a top performer for mercury in the liquid subcategory. It is a 1977 vintage firetube boiler burning No. 6 fuel oil with no controls. The average equivalent Hg content based on fuel sample analysis is 29.6 lb/TBtu. However, the emission rate per emissions test average is identified as 0.086 lb/TBtu. As there is a tremendous difference between apparent oil Hg level and emissions test level and this unit has no control device, EPA should quality assure the fuel and test data.

* For several of the listed liquid subcategory top performers, the fuel analyses for Hg indicated Hg contents below detection levels (NJVinelandMuniElectric-HowardDown- Unit 9, SCMilliken-Dewey- D30, NYConEd59thStStationNewYork- Boiler 118, PABoeingRidleyPark-033, ILCognisCorp- Boiler #2 & #1, INUSSteelGaryWorks- O4B10459). Use of data from boilers firing fuels with no detectable Hg content to set emission limits for all liquid-fired boilers is not appropriate. If EPA continues to use these data, they should at least be adjusted upward to represent a measurable quantity.

* PAConemaughPowerPlantNewFlorence Aux Boiler B is listed as a top performer for PM in the liquid subcategory. Emission test results for the 3 runs were 0.0013, 0.00032, 0.001 lb/MMBtu. Without the test report there is no way to identify if there were issues with the second run that led to significantly lower emissions than the other two runs, but we question the validity of the second run. For comparison, the other auxiliary boiler at the site, a similar size unit, showed PM emissions of 0.009, 0.0087, 0.0047 lb/MMBtu for an average of 0.0075 lb/MMBtu, much more in line with Runs 1 and 3 for Boiler B. EPA should investigate the validity of the Boiler B data.

* NJSunocoWestville Boilers #5, #6, #7, #8 are top performers in the liquid subcategory. However, it was publicly reported that this refinery was shutdown in 2009, so these boilers should be removed from the database.

* NENebraskaCityStation Auxiliary Boiler 2 is listed as a top performer for CO in the liquid subcategory. EPA lists average CO emissions of 0.2733 ppm @3% O2 dry, which is the average of the 3 reported runs. Per the emissions test report, it appears the NDIR analyzer was set up with a 1000 ppm span, with upscale calibrations between runs using 229 ppm CO cal gas. Therefore, at best the M10 accuracy specification of +/- 5% of span would allow for an accuracy of +/- 11.45 ppm CO. Thus, the reported data from this test indicating 0.27 ppm is well below the potential accuracy limitations of the methods used.

* OHOSUColumbus B140 is listed as a top performer for CO in the liquid subcategory. EPA lists average CO emissions of 0.54434 ppm @3% O2 dry, which is the average of the 3 reported runs, however 2 of those were reported at < 0.5 ppm (DL). The M10 analyzer was used with a 100 ppm calibration span. The reported results appear lower than the M10 accuracy specification warrants for use in establishing a MACT Floor.

* NCCampLejeuneMCB C-CG-650-83B and 84B are listed as top performers for CO in the liquid subcategory. EPA lists average CO emissions of 0.8667 and 0.5667 ppm @3% O2 dry for 83B and 84B, respectively, which are the average of the 3 reported runs for each boiler firing No. 2 Oil. The M10 analyzer was used with a 246 ppm calibration span. The reported results appear lower than the M10 accuracy specification warrants for use in establishing a MACT Floor.

* VADominionPossumPoint Aux. Boiler 001 is listed as a top performer for CO in the liquid subcategory. EPA lists average CO emissions of 0.6286 ppm @3% O2 dry, which is the average of the 3 reported runs. However, the emission test report indicates that the boiler fired natural gas during the emissions testing; therefore, this unit is not appropriate to include for setting a liquid fired unit MACT Floor.

* PAKeystonePowerPlantShelocta Aux Boiler A is listed as a top performer for CO in the liquid subcategory. EPA lists average CO emissions of 0.7590 ppm @3% O2 dry, which is the average of the 2 reported runs. The M10 analyzer was used with a 149 ppm upscale calibration span gas. The reported results appear lower than the M10 accuracy specification warrants for use in establishing a MACT Floor.

* WINewPageKimberly Boilers 21 and 22 burn coal and share a common stack. They are not currently listed as top performers in the coal subcategory. However, their mercury data in the database are 1000 times higher than the actual test data. The data should be 1.74E-06, 1.56E-06, and 1.88E-06 lb/MMBtu (the data are listed as 1.74E-03, 1.56E-03, and 1.88E-03 lb/MMBtu).

Response: The specified data corrections have been processed in the EPA database.

Comment: We have noted that there are several boilers, some listed as top performers, that have been mis-categorized:
* LAShellChemicaGeismar Furnace F-S801 is not a Gas 2 boiler, but should be categorized as a liquid boiler because it burns heavy recycle.
* WIGPGreenBay2818 B10 - Wastepaper Sludge-Fired Boiler 10 is not a liquid-fired boiler. This boiler burns secondary fiber deinking residuals to produce steam for the secondary fiber papermaking process. Secondary fiber deinking residual is a biomass fuel consisting of recovered fiber from the deinking process that cannot be made into paper. Fuel analysis data for 2007-08 indicates an average deinking residual HHV of 2575 Btu/lb (4400 Btu/lb dry), with moisture of 42%. Similar analyses for 2009 indicate a moisture content of 41% and a dry HHV of 3875 Btu/lb. Therefore this unit should be included in the biomass category.
* LAGPort Hudson - EQT0109 No. 6 CFB is listed as a biomass boiler. This boiler burns more than 10% petroleum coke along with biomass and some natural gas to make steam for the papermaking process. The probable reason for this boiler being mischaracterized is that during EPA's Phase I Information Collection Request (ICR) there was no choice in the drop down menus for petroleum coke and the instructions told responders to select coke oven gas instead. Therefore, this boiler should be in the coal category since it burns more than 10% petroleum coke.
* The following boilers also have been listed as burning coke oven gas when in fact they burn petroleum coke:
GASRMRincon – EU B002: This boiler is incorrectly listed in the Gas 2 category but should be listed in the coal category because it burns 100% petroleum coke but does not burn coke oven gas.
GASRMRincon – EU B003: This boiler is correctly listed in the coal category and burns a combination of coal and petroleum coke, but does not burn coke oven gas.
GASRMRincon – EU B001: This boiler is correctly listed in the coal category and burns a combination of coal and petroleum coke, but does not burn coke oven gas.
WIGPGreen Bay0218 – B29-Fludiized Bed Boiler #9: This boiler is incorrectly listed in the Gas 2 category but should be listed in the coal category because it burns 100% petroleum coke but does not burn coke oven gas.
We suspect that there are many other boilers in the database that have not been placed in the correct subcategory and are inappropriately influencing MACT floors.

Response: The specified data corrections have been processed in the EPA database.

Comment Excerpt Number: 58

Comment: EPA must scrutinize the emission test database for potential problems with units having multiple tests where a top performer may not be identified because of inappropriate grouping of test runs. Two such examples in the biomass subcategory follow:

* MESDWarrenSomerset, No.2PowerBoiler – EPA improperly grouped sample runs creating substantial differences in test event averages for filterable particulate matter. A two run set (4-14-08) and a four run set (4-21-08) were treated as two three run sets. For one of the two sets the average value should be more than twice the current value.
* FLRayonierPerformance, PB06 – The boiler was tested in 2008 with three fuel mixes. Two sample runs were conducted per fuel mix. These six runs should represent three test events. EPA grouped the data as two three run sets (dioxins/furans and perhaps other pollutants).

Response: The specified data corrections have been processed in the EPA database.

Comment: It is noted that a wet ESP was installed in 2007 on this boiler, so it is appropriate to segregate test data gathered before and after installation of this device. However, the control device listed in the Version 5 emissions database is a wet ESP for all test dates, which is not accurate.

Response: The specified data corrections have been processed in the EPA database.

Comment: NCASI also conducted detailed reviews of the 2009 ICR test reports for several boilers. One component of that review was the handling of reporting of measurements below the

method detection limit (or reporting). Due to lack of an EPA procedure of determining the detection limits in EPA Method 29, the data included in EPA's database and used to set the MACT emission standards includes a significant amount of data reported using the reporting limits. The overall range of the DLs/RLs for the sources reviewed was from 0.047 to 0.84 µg, which represents a factor of 20.
This analysis once again highlights the need for detailed report review and using consistent data prior to utilizing the data for setting the standards.

Response: EPA incorporated data updates based on many of the NCASI findings in the test reports. EPA also conducted an independent review of 4 test reports from low emitting sources to evaluate whether all mercury fractions were treated appropriately.

Comment: The boilers at FLUSSugarCorp, FLOsceolaFarms and FLSugarCaneGrowersCoop (except Boiler No. 1) are all listed as spreader stokers. Boiler No. 1 at FLSugarCaneGrowersCoop is listed as Other – water-cooled pinhole grate. The CO information from these boilers should be put in the appropriate subcategories. The dioxin/furan information for WAGraysHarborPaper No. 6 Boiler and ORRosboroSpringfield DV 01.1 should be in the Dutch oven subcategory and that for ORFlakeboardEugene Boiler-2 in the suspension burner subcategory.

GATempleInlandThomson BW-B001 is listed as a stoker/sloped grate/other in the Version 5 emissions database, but as a package watertube wall-fired boiler in the survey database. This unit burns sanderdust, natural gas, and distillate fuel oil, and should be in suspension burner subcategory.

Response: The specified data corrections have been processed in the EPA database.

Comment: EPA did not make MACT floor memo Excel files available in the docket for the Boiler rule until 3 weeks into the original 60-day comment period.

The rules would also benefit significantly from the generation of additional emissions information. EPA's MACT Floor tables indicate that eleven of the thirty MACT Floor emission limitations for existing sources were determined using less than five sources due to a lack of available data.6 No time was allocated for additional data-gathering.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2841.1, Excerpt Number 9.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 33

Comment: The database used for this rulemaking is rife with anomalies due to apparently erroneous identification of fuels fired, equipment type, incorrect conversion of reported results to standardized units and data transcription and import errors, reporting errors, and other issues. Therefore, the quality of the data in EPA's database is inappropriate for use in setting emission standards of any kind, much less national standards affecting hundreds to thousands of individual units. Many of these issues could be resolved simply by reviewing all of the information provided to EPA via the ICR such as primary data (field data, laboratory reports, etc.) submitted with test reports and resolving anomalies via communications with the facility. In Attachment A, we list many specific anomalies identified during our review; this list is not comprehensive, but indicative of the types of issues encountered during our review. In several cases, the source of the anomaly was identified, confirmed via contact with the facility and correction action was identified. This section focuses on anomalies in the data used by EPA. In Comment VI.B.1 we discuss the failure of this data to properly represent the source category.

Recommendation: Since the rule impact is so extreme, the Agency should verify every entry, individually, with the boiler or process heater owner/operator and against the test report or CEMS output to validate all of the data used in this rulemaking. At a minimum, every data point for units in the floor and all data in small data sets (e.g., <30 units) should be individually validated. All anomalies identified in Attachment A and in comments of others must be resolved.

Response: The specified data corrections have been processed in the EPA database.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 37

Comment: * The database contains data for units that are excluded from the proposed rule. For instance, 63.7491(j) excludes blast furnace gas-fired boilers and process heaters, but such units are included in the database.

Response: Blast furnace units co-firing with other fuels are covered under this standard. There are no units firing 100 percent blast furnace gas that are used as a basis of the floor calculations.

Commenter Name: Leonard W. Sandridge
Commenter Affiliation: University of Virginia
Document Control Number: EPA-HQ-OAR-2002-0058-2769.1
Comment Excerpt Number: 38

Comment: We reviewed UVA data (Facility ID = VAUniversityofVirginia) in the survey database and noticed the following omissions or inconsistencies:

Data: Control Device Table
* 5575-1-01, 5575-1-02, 5575-1-03, and 5575-1-04 were omitted. These boilers are all equipped with low NOx burners.
* Boilers 7103-1-03R and 7103-1-04R were omitted. These boilers are equipped with low NOx burners and flue gas recirculation (FGR).
* In addition to the controls noted in the database, our coal boilers 7103-1-01R, 7103-1-02R, and 7103-1-05 control NOx emissions using over-fire air and FGR when firing coal and low NOx burners and FGR when firing natural gas.

Data: Emission Test and CEMS Installed Table

The following boilers were included in our survey but were omitted from this data table:
* 0207-1-01, 0231-ICU-01, 0580-2-01, 0603-1-01, 5576-1-01, 5575-1-01 though 5575-1-04, 5576-1-02, 5577-1-01, 7103-1-03R, 7103-1-04R, 7533-1-01, and 7533-1-02.
* Unit ID 2116-ICU-01 should be replaced with the correct numbering 2616-ICU-01.
* The “CO Test” and “PM Test” columns for 7103-1-01R, 7103-1-02R, and 7103-1-05 indicate False, while we submitted CO and PM test data.

Data: Emissions Test Background Info Table

* Boilers 5575-1-01 through -04 are equipped with low NOx burners; currently the “Standardized Control Device” column indicates no equipment.

* Boilers 7103-1-03R and 7103-1-04R are equipped with low NOx burners and FGR; currently the “Standardized Control Device” column indicates no equipment.
* For Boiler 7103-1-01R with a test date of 12/5/07, Boiler 7103-1-02R with test date of 1/15/04, for Boiler 7103-1-05 with test date of 4/2/08, only natural gas was fired. When only natural gas is fired, the control devices used are low NOx burners and FGR. No other controls are used but the “Standardized Control Device” column indicates otherwise.
* All other test dates for Boilers 7103-1-01R, 7103-1-02R, and 7103-1-05 involved firing coal. The control devices used include overfire air, FGR, cyclone, spray dryer, and baghouse. All or some of these controls are omitted from the “Control Device” and “Standardized Control Device” columns.

Data: Emissions Test Fuel Data Table The heat input data in the “Standardized Fuel Rate” column for all Boiler 7103-1-05 test runs and Boiler 7103-1-01R December 2007 test runs are noticeably lower than the values we provided in our questionnaire.

Data: Regulatory and Permit Limits Table

All of our boilers, except those at our main heat plant (7103-1-01R through 7103-1-05) have one set of emission limits in our state air permits. Depending on the pollutant, the limit is baesd on calculated from AP-42 emission factors for either natural gas or distillate oil combustion, whichever is higher for our gas/oil boilers. In the survey, we indicated which fuel the limit was based on, but the limits are applied irrespective of the fuel burned. This may not be how the question was intended to be answered.

Our main heat plant boilers have discrete emission limits for each fuel burned (natural gas, distillate oil or coal). We provided all these emission limits in our survey, but not all of the emission limit-fuel combinations were imported to the database.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 43

Comment: As demonstrated by the large number of mis assignments listed in Attachment A, it is clear the data doesn‘t adequately indicate which of the proposed subcategories a particular unit should be assigned.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 66

Comment: CIBO also doubts whether EPA has performed a thorough Quality Assurance/Quality Control (QA/QC) review of the database itself. The background document in the docket providing EPA's floor analyses for the potential Gas 1 floors in the preamble indicates that EPA included in its analysis direct-fired process heaters, which are not supposed to be included in the rule. Specifically, EPA included a direct-fired rod/bar mill furnace, CORockyMtnSteel212, among the natural gas-fired units comprising the floors for HCl, CO and D/F. According to the owner and operator of the Rocky Mountain Steel unit, the unit is a direct-fired re-heat furnace where steel billet intermediate product comes into direct contact with the products of combustion. This explains why the test data for the unit shows such low CO and D/F levels. Such database errors call into question whether EPA has included the correct units in the database used to set the MACT floors in the proposal and whether EPA has undertaken the necessary QA/QC of the database.

Response: The specified data corrections have been processed in the EPA database.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 245

Comment: Attachment A - Identified Data Inaccuracies
1. F-S801 and F-S2801 at Shell Chemical, Geismar, LA, are liquid-fired furnaces per the proposal definition. Their inclusion in the Gas 2 floor is a mistake.
2. Boiler-U202 at Shell Chemical, Geismar, LA fires enough petrochemical process gas to make it a Gas 2 unit, not a Gas 1 unit.
3. B 29 at Georgia Pacific, Green Bay, WI, is Petroleum Coke fired boiler. Its inclusion in the Gas 2 floor is a mistake.
4. B 10 at Georgia Pacific, Green Bay, WI is a Wastewater Sludge fired boiler. Its inclusion in the liquid fired floor is a mistake.
5. EU B 02 at Georgia Pacific, Riincon, GA is a Petroleum Coke fired boiler. Its inclusion in the Gas 2 floor is a mistake.
6. The Hg results for liquid-fired EU 33 Boiler # 3 at Georgia Pacific, Duluth, MN appear invalid. Non-detects were reported as zero, rather than at the detection limits and the tests were run for short times, resulting in particularly high detection limits, thus making the error very significant. Further, the stack results appear to be at odds with the fuel analyses and the stack results are not representative because that stack normally receives emissions from three boilers, but only one was operating, making the Hg removal in the stack ESP higher than normal, among other unusual factors. This data should be discarded.

7. The CO emissions measured in the EPA required test at F-562 at the Western Refining Yorktown, VA was 49.3 ppm @ 3%O2 not 49.3 ppb @ 3% O2 as indicated in the database and floor analysis.
8. Process Heater 1-90 at Westlake Styrene, Westlake, LA is indicated as a Gas 1 process heater, but is believed to have been firing a high hydrogen Gas 2 mixed fuel when the performance test data included in the database was obtained 18 years ago. It is unclear that this 18 year old stack test is valid for the current heater and fuel.
9. Boiler 7103-1-01R at the University of Virginia, Charlottesville, VA, is included in the database as a Gas 1 unit, but is a coal stoker unit. It does fire natural gas as well, but is optimized for coal and meets the proposed definition of a coal unit and does not meet the proposed definition for a Gas 1 unit.
10. The CO value for Boiler G at Equistar Chemical, LaPorte, TX is incorrect in the EPA database. The correct value is 3.39E+01 ppmv @ 3% O2, not 2.11E-02 ppmv @ 3% O2. The value reported was the uncorrected CO concentration and the unit of measure was incorrectly picked as ?g/dscm @ 3% O2 on the survey form. The correct unit of measure selected should have been ppmv @ 3% O2.
11. HS-2041A, B, and C at Hunt Refining, Tuscaloosa, Alabama are included in the database as Gas 1. On average, these units fire 29% Refinery Fuel Gas and 71% PSA Off Gas. While PSA off-gas is often in refinery fuel gas, under the proposal definitions it appears this unit should be reassigned to Gas 2 subcategory.
12. For heater 24-F-1 at the ExxonMobil Refinery, Torrance, CA the stack mercury concentration in lb/MMBTU was miscalculated, because the heat from the Gas Turbine exhaust used as combustion air for this heater was not considered.
13. The dioxin data for the natural gas-fired 150 Furnace at Cytec, Wallingford, CT are misreported as detected levels that are improbably high for natural gas-fired process heaters. The analytical detection limits are reported as mass (pg) rather than as equivalent in-stack concentrations (ng/dscm), and the detection status should have been indicated as DLL indicating some congeners were detected and some are undetected. This results in an average TEQ in the EPA database that is approximately 5000 times higher than the correctly calculated value.
14. The CO emissions from EUCOG-5 #2 gas-fired boiler at Archer, Daniels, Midland, Clinton, Iowa were 0.1 ppm at 3% O2, not 0.1354 ppm@3% O2.
15. The North Variants Boiler at Rubicon LLC, Geismar, LA was firing vent gas (for HCl MACT) and natural gas when tested and should have been assigned to Gas 2, not Gas 1. HCl results are widely scattered and high, raising questions about the quality of the data and the unit operation during the test.
16. Powerhouse Boiler 3 at the Ford Assembly Plant, Wayne, MI fired primarily landfill gas and thus is a Gas 2 unit, not Gas 1.
17. Boiler NO. 4 at Dover light and Power, Dover, OH is shown in the site permit as coal fired, not Gas 1.
18. The Hg results for HB03 at BMW Manufacturing, Greer, SC did not include detection limits for undetected results in summing the separate analytical fractions, resulting in the reported results being a factor of 3 too low. The Hg value for this unit should be recalculated using the detection limit for undetected values.
19. Hg result for HTM Heater 3 at Eastman, Columbia, SC contains several errors and must be corrected. Analytical fraction 3A was omitted from all runs, indicating a possible method deviation voiding comparability to other tests and introduction of a low bias compared to other

tests with all five analytical fractions included (because an undetected result for this sample fraction is not included); sample fraction 5C (analytical fraction 3A) was not collected in Run 1, introducing a low bias compared to other test runs. Mercury detection limits were not included in the sum of separate analytical fraction results for total mercury catch. Average result including detection limits and typical values for missing fractions is 1.7 times higher than reported result.
20. ACET-2A-1 ACET 2A-5 and ACET 2B-1 ACET 2b-5 at Rohm and Haas, Deer Park, TX have been shutdown since 2008 and should not be included in the database.
21. Heater 13-1451 at Valero Refining, Texas City, TX reports that while the source test results were < 0.1 ppm CO @ 3% O2 for all three test runs, CO typically ranges from 0-540 ppm and a monthly average of 11 ppm is typical.
22. Heaters 16 and 17 at Valero Refining, Texas City share a common stack. The site reports that while the source test results were < 0.1 ppm CO @ 3% O2 for all three test runs, CO has varied from 0 to 512 ppm over the last 18 months, with a monthly average of 7.6 ppm (standard deviation 13.2 ppm).
23. Heater 58 at Valero Refining, Texas City, TX reports that while the source test results were < 0.1 ppm CO @ 3% O2 for all three test runs, CO has varied from 0-875 ppm over the past 18 months, with a monthly average of 48 ppm (standard deviation 75.1 ppm).
24. The H2 Plant heater and Heater B-7 at Solutia, Inc., Pensacola, FL fire process gas and natural gas and meet the Gas 2 definition in the proposal, not the Gas 1 definition.
25. The Cold Mill Annealing Oven at Nucor Steel, Crawfordsville, IN should be included in the Gas 1 metal industry subcategory, not the Gas 1 subcategory.
26. EU-39-FH0027 at Coffeyville Refining, Coffeyville, KS is a coal-fired boiler which should be moved from the Gas 1 subcategory.
27. HB-513 at Deltech, Baton Rouge, LA fires natural gas and landfill gas and meets the Gas 2 definition not the Gas 1 definition.
28. Power Boiler 4 at Potlatch, Lewiston, ID fires mostly solids and does not belong in the Gas 1 database.
29. Power Boiler 6 (EU ID 03) at IP, Pensacola, FL fires natural gas and landfill gas and should be in the gas 2 subcategory not Gas 1.
30. The large boiler at Zeeland Farm, Zeeland, MI fires primarily landfill gas and is thus a Gas 2 unit, not Gas 1.
31. Boiler 3 at Severstal, Sparrows Point, MD fires blast furnace gas and belongs in the Gas 2 subcategory, not the Gas 1 subcategory.
32. ES-41 at Cargill, Fayetteville, NC fires natural gas and landfill gas and belongs in the Gas 2 subcategory, not the Gas 1 subcategory.
33. Boilers 2, 9, 10, and 11 at Texas Petrochemicals fire natural gas and petrochemical gas and thus meet the Gas 2 subcategory definition, not the Gas 1 definition.
34. Boiler P-25 at Equistar, Pasadena, TX fires natural gas and petrochemical process gas and meets the Gas 2 subcategory definition, not the Gas 1 definition.

Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 270

Comment: The Gas 1 dioxin/furan data set consists of 8 units (Figure 11). One is coal-fired and another is co-fired on liquid fuel. All but one of the units has no emission controls. There is one unit with SCR, with emissions at essentially the same level as the uncontrolled units. There is one uncontrolled unit with apparently much higher emissions (#8). Review of the test report shows that these data are over-reported by a factor of approximately 5000 due to mis-reporting of detection limits (analytical mass instead of in-stack concentration).

Response: The specified data corrections have been processed in the EPA database.

Document Control Number: EPA-HQ-OAR-2002-0058-2785.1
Comment Excerpt Number: 2

Comment: Stack Test Submittal: As a part of the information gathering activity in 2008, Westlake Styrene LP provided a Stack Test Report from a 1992 Test of a Process Heater at the Westlake — Lake Charles Complex. The Stack Test Report was identified as a Natural Gas fueled source. Upon further review of the Stack Test Report it was determined that the fuel for the Process Heater during the 1992 Stack Test was a combination of natural gas and process gas. The process gas stream is primarily Hydrogen. We feel that the use of this Stack Test for the MACT Floor for Natural Gas Boilers and Process Heaters Carbon Monoxide emissions is incorrect and should be corrected. Westlake apologizes for this discrepancy.

Response: The specified data corrections have been processed in the EPA database.

Document Control Number: EPA-HQ-OAR-2002-0058-2747.1
Comment Excerpt Number: 3

Comment: Since the release of the data used by EPA to establish the proposed standard, the National Council for Air and Stream Improvement (NCASI) has examined about 100 stack test reports and associated laboratory analysis reports for filterable particulate matter, dioxin/furan, mercury, HCI, formaldehyde, and/or total hydrocarbons (THC). Most of these reports were for boilers assigned to either the biomass or coal subcategories, and most were listed in the EPA database as being among the units with an emission test in the lowest 12% for filterable particulate matter, dioxin/furan, mercury or HCI. NCASI found a disturbing number of problems with the test results appearing in the EPA database for these so-called 'best performing' boilers. It was obvious the test results being used to develop the proposed emission limits had not received an adequate review. Some of the problems identified by NCASI, when corrected, will have a dramatic impact on the proposed emission limits. It is imperative for EPA to thoroughly review all of the available data for the top performing units before promulgating emission limits.

The assessment conducted by NCASI does not by any means encompass a complete review of the database EPA used, but it is alarming that so many errors were found during the short amount of time that was allotted for review during the comment period. For example, of the 11 biomass boilers identified by EPA as best performers for mercury, NCASI identified problems with 7 of those tests that would have resulted in either the source not being identified as a best performer in the first place or would have raised the reported value by at least a factor of two in some cases and an order of magnitude in others.

Commenter Affiliation: MeadWestvaco
Document Control Number: EPA-HQ-OAR-2002-0058-2747.1
Comment Excerpt Number: 5

Comment: It is incumbent for EPA to perform a thorough review of all stack sampling and associated laboratory analysis reports for the Phase I and II information collection requests, ICR, at least for units currently identified as lop performers' in the various subcategories since errors will affect the currently proposed limits. EPA needs to ensure that all Phase I results are compatible with the Phase II protocols, as well as with the compliance test methods and reporting requirements to be promulgated in the final rule. The Phase II test reports should also be carefully examined and checked to insure the sampling was conducted properly and the emission rates and method detection levels were calculated according to the Phase II protocols.

MWV is very concerned about the achievability of complying with the limits EPA has proposed. EPA is obligated to establish
standards based on performance of the average of the top 12 % units within a specific category.

Document Control Number: EPA-HQ-OAR-2002-0058-2737.1
Comment Excerpt Number: 7

Comment: We are also concerned about the reporting of ICR data using the electronic reporting tool (ERT) and spreadsheet reporting templates (SRT). For example:

We experienced various data entry problems with the use of both the ERT and SRT which we explained to EPA in email and teleconferences. We believe that several of the problems were corrected; however, the ICR data set may include data that were generated using earlier and improperly functioning versions of these tools. Additionally, these tools do not provide audit or check functions so it is possible that some data have not been properly reported or qualified. WESTON encourages EPA to develop a structured audit program that includes comparison of ERT/SRT data with hard copy data reported by the source and develop appropriate corrective action.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Affiliation: Edison Electric Institute
Document Control Number: EPA-HQ-OAR-2002-0058-2755.1
Comment Excerpt Number: 8

Comment: Within these severe time constraints, the industry conducted a spot check of 100 stack test reports and associated information from top performers in order to assess the quality of the data the agency relied upon in calculating the MACT floors that underlie the proposed rule.

This spot check revealed numerous data errors – many of which, if corrected, would have a material impact on the stringency of EPA's calculated MACT floors and associated proposed standards. A few illustrative examples include: (1) widespread inconsistency in the data reported under the Phase I and Phase II ICRs, such as entirely different methods of determining and reporting "non detects"; (2) inconsistent reporting of dioxin/furan emissions testing results; (3) inconsistent and incompatible PM emissions testing methods; and (4) mischaracterization of boiler types, such as including a coal-fired boiler in the biomass subcategory. The number and magnitude of the errors provide clear evidence that the database is fundamentally flawed and that any standard derived from the database does not have adequate factual support.

To resolve this problem, EPA must conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for public comments (including sufficient time for commenters to conduct their own comprehensive review of the data).

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Name: Thomas Bakk
Commenter Affiliation: State of Minnesota Senate
Document Control Number: EPA-HQ-OAR-2002-0058-2950
Comment Excerpt Number: 8

Comment: Although it has not been possible to conduct a thorough quality assessment of the entire EPA emission database, AF&PA has done a spot check of one hundred stack test reports. The spot check revealed numerous errors that may have affected the MACT floors and the stringency of the proposed emission limits. It appears that the database is fundamentally flawed, therefore calling into question the factual basis for the standards. The EPA should review the database and correct or eliminate the flawed data and recalculate the emission limits. In addition, because the EPA has not finalized the waste rule definition, the proposal sets out a range of possible final rules, creating a situation where interested parties cannot know which data will ultimately be used to set the emission limits. The definition must be determined before the MACT limits are proposed.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Name: Jon T. Howard

Document Control Number: EPA-HQ-OAR-2002-0058-2737.1
Comment Excerpt Number: 9

Comment: The ERT and SRT allowed for the inclusion of interpretive and clarifying comments (which we used, particularly in connection with item 2 above). It is not clear if or how these comments were used by EPA when developing the proposed rules. In the case of data submitted by WESTON, these comments provided important information that would govern the use of reported data. In short, the comments for ERT and SRT submittals were equivalent to the “discussion” component of the “Results and Discussion” section of a standard emission testing report. Accordingly, WESTON encourages EPA to carefully consider all comments accompanying ERT and SRT submittals.

Response: To the extent allowable under this rule schedule, EPA reviewed supporting data provided to explain data. EPA focused its review on the data on low emitting units in order to ensure that data from potential top performers was not erroneous.

Comment Excerpt Number: 11

Comment: Errors in data used

Review of the top performer unit emissions data and supporting information, including emission test reports indicates many significant problems, including errors in reporting and interpretation, use of emission rates that do not comply with EPA instructions relative to reporting of analyses below detection levels (reporting zero for M29 fractions that are <DL instead of reporting DL), use of emission rate data that is well below the accuracy of the test method and CEMS equipment, and others. The CIBO comments elaborate on examples of specific issues. It is imperative that every set of data used for determining a MACT Floor is carefully reviewed for quality assurance, quality control, and for identification and correction of errors if that can be done. EPA simply must do this to have a defensible outcome.

Response: See response to DCN EPA-HQ-OAR-2002-0058-3213.1, Excerpt Number 68.

Commenter Name: David Bonistall
Commenter Affiliation: NewPage Corp
Document Control Number: EPA-HQ-OAR-2002-0058-2920.1
Comment Excerpt Number: 21

Comment: EPA needs to conduct a thorough data quality assessment on the Boiler MACT database. A spot-check review was conducted on about 100 stack test reports and other information from top performers in order to assess the quality of the data used by EPA to calculate the MACT floors for the proposed rule. This spot-check analysis revealed a number of data errors, which when corrected, will impact the stringency of the proposed standards.

These errors raise significant concerns about the quality of the data in the database being used to establish the Boiler MACT standards. Any standard developed from a database that is fundamentally flawed will not have adequate factual support. EPA can resolve this problem by conducting a thorough review of the database and provide sufficient time and opportunity for public review and comment.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Name: Pamela F. Faggert

Document Control Number: EPA-HQ-OAR-2002-0058-2908.1
Comment Excerpt Number: 24

Comment: EPA subcategorized Dominion's Possum Point — Aux Boiler 001 as a "Liquid-fired" unit rather than a "Gas1-fired" unit. This unit only fires natural gas. This error is particularly significant since this unit was included in the
emissions floor analysis for CO for liquid-fired units and identified as the 11th best performing oil-fired unit with regard to CO emissions. This unit does not belong in the liquid fuel subcategory, much less as a "best performing" unit that is used to set the MACT floor for that subcategory. To resolve these problems, EPA should conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for
public comments through a supplemental notice of proposed rulemaking (SNPR).

Response: The specified data corrections have been processed in the EPA database.

Comment: Our review of EPA's ICR database suggests that EPA did not adequately review the ICR emissions data prior to conducting the MACT floor analysis. While we understand that an in-depth review of such a massive amount of data would be difficult given the limited timeframe for rulemaking, many of these issues could have been identified by simple outlier screening.

As a starting point for revising the proposed rule, RMB recommends that EPA conduct a more thorough investigation of the ICR data quality. At a minimum, EPA should perform an outlier check of all reported test data, including outliers within each reported test and outliers between tests for units that reported multiple tests. EPA could then exclude such test data or conduct further investigation to confirm whether the data is truly an outlier.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Comment: EPA inappropriately subcategorized VADominionPossumPoint – Aux Boiler 001 as a “Liquid-fired” unit rather than a “Gas1-fired” unit. RMB has confirmed that this unit only fires natural gas. This error is particularly significant since this unit was included in the emissions floor analysis for CO for liquid-fired units.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 51

Comment: EPA identified the ASEA Boiler No. 1 owned and operated by Archer Daniels Midland (ADM) in Des Moines, IA as the best performing coal-fired unit with respect to PM emissions. The reported filterable PM emissions for this unit is 0.0002 lb/106 Btu.16 An examination of the test report also shows average filterable PM2.5 emissions to be 0.0096 lb/106 Btu. For a well-controlled source, PM2.5 is typically at least 50 to 60 percent of total filterable PM emissions. These results suggest that at least one of the two PM averages must be incorrect since the total filterable PM emissions is approximately 50 times less than filterable PM2.5.

Response: The test report for this test was reviewed. It was found that the filterable PM values were from a combined Method 5/29 test. A separate OTM 27/28 train was conducted, and the PM2.5 values were taken from it. The filterable PM values reported with the OTM 27/28 train were much higher than the Method 5/29 train, thus the reason for the much larger PM2.5 values. The validity of both values were confirmed, but they should not be compared to each other because they were not measured concurrently.

Comment: 10. Some of the emissions test data were obtained under non-isokinetic test conditions. All isokinetic reference methods specify that isokinetic variation must be limited to ±10%. Test results that are outside of this specification may be rejected at EPA's discretion. A complete list of test runs there were performed during non-isokinetic test conditions can be found in Attachment D of the submittal.

Response: Although the commenter provided a general cutoff for excluding isokinetic variation for some stack tests, other variables must be considered when evaluating the reliability of a test. EPA conducted a detailed review of 17 tests and eliminated some due to improper ISO variation. Further, the facilities performing these tests did not report to EPA that these tests were invalid and given the cursory threshold provide by the commenter without any site-specific testing notes. EPA did not use its discretion to remove this data from consideration.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1

Comment: RMB conducted limited outlier screening of the ERT data reported for some of the biomass, coal, and oil-fired units. Potential outliers were determined by assessing the inter-run variability for each test using a logarithmic difference [Footnote: Algorithm compares the absolute difference of the log10 value of each run to the log10 value of the average of the remaining runs against an outlier threshold value of 0.7 (detects variation that is greater than 105 times the difference).] screening algorithm. RMB recommends that these test runs be further investigated to determine whether they should be eliminated from the MACT pool. (See submittal Attachment F for a list of potential outliers.)

Response: The specified data were not further investigated due to time constraints. No further correspondence was received on the specified potential outliers, so none of the specified data was disregarded from MACT floor rankings.

Comment Excerpt Number: 1

Comment: In 2009, a second ICR mandated extensive stack testing and fuel analyses at roughly 150 boilers and process heaters. EPA selected these units to fill perceived information gaps in the database and to obtain additional test data from numerous 'best performing' units to examine emissions variability. Companies were given only four months to conduct this testing and submit the results to EPA. Four (4) of Domtar mills (Kingsport, TN, Plymouth, NC, Bennettsville, SC and Ashdown, AR) participated in this exercise, at a total cost to Domtar of over $400,000.
The combined database for the 2008 and 2009 data contains a massive amount of information and it is unrealistic to expect that every value in the database has been checked by EPA and its contractor for accuracy. Indeed, several errors in the data submitted by Domtar were found and corrections were sent to EPA before and after the date of publication of the Proposed Rule. However, only a small fraction of the emission
test results in the database has actually been used for developing the proposed numerical standards (Ashdown's results, which included long term variability testing, were excluded) and it is realistic to expect this more limited set of information has been thoroughly reviewed and cross-checked.

Comment: Given the limited comment period that has been provided on the proposed rule, it simply has not been possible to conduct a thorough data quality assessment on EPA's entire emissions data base. Within these time constraints, the National Council for Air and Stream Improvement conducted a spot check of 100 stack test reports and associated information from top performers in order to assess the quality of the data the Agency relied upon in calculating the MACT floors that underlie the proposed rule.
This spot check revealed numerous data errors – many of which, if corrected, would have a material impact on EPA's calculated MACT floors and associated proposed standards. To name just a few, there was: (1) widespread inconsistency in the data reported under the Phase I and Phase II information collection request (ICR)s, such as entirely different methods of determining and reporting "non detects"; (2) inconsistent reporting of dioxin/furan emissions testing results; (3) inconsistent and incompatible PM emissions testing methods; and (4) mischaracterization of boiler types, such as including a coal-fired boiler in the biomass subcategory. The number and magnitude of the errors provide clear evidence that the database is flawed and that any emission standard derived from the database does not have adequate factual support.

To resolve this problem, EPA must conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for public comments (including sufficient time for commenters to conduct their own comprehensive review of the data).

Comment: One of our biomass boilers at the AFP Urbana, AR mill, SN-12, is shown as one of EPA's top performer for dioxin /furans in the fuel cell/biomass subcategory. However, the database contains multiple errors for this very unit and pollutants. At least two attempts [Email from GBMc & Associates on behalf of AFP to CombustionSurvey@erg.com on 2/22/2010 and to Mr. Brian Shrager on 7/6/2010.] to correct EPA's data collection regarding the facility's units have been made.

Response: The specified data corrections have been processed in the EPA database.

Commenter Name: Timothy J. Porter
Commenter Affiliation: Wheelabrator Technologies Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2812.1
Comment Excerpt Number: 2

Comment: The three (3) WTI "CA Wheelabrator Shasta" biomass fired boilers at our California renewable energy facility were included in the proposed CISIWI MACT rule based on the proposed solid waste definition rule. The inclusion of the CA Wheelabrator Shasta most likely was based on the fact that these units were permitted years ago to combust small amounts of solid waste (such as paper cubes and cardboard) although these fuel types have not been combusted in years. Subsequently these units should be appropriately included in the universe of Boiler MACT units and emissions data subsequently used to derive Boiler MACT limits if they represent the top 12% performing units.

Response: The three Wheelebrator Shasta boilers have been moved to the inventory of major source boilers and process heaters.

Comment Excerpt Number: 3

Comment: Additionally, the TPC has grave concerns about the quality of data used to establish the MACT floors. A limited review by our industry of the data that have been used to set the boiler MACT standards identified errors in units of measure, fuel and boiler categorization, detection limit calculation and measurement techniques. We are very concerned that a rule which impacts not only select sources within our own industry, but also the entire breadth and depth of the nation’s manufacturing sector’s steam and power generating units, establishes emission limits based data that has obvious errors.

We ask EPA to recalculate the proposed limits in a fashion that establishes the MACT floor for each subcategory by identifying the top performers (from the entire population of units in the subcategory) on the basis of the collective, not independent, emissions of the pollutants or pollutant surrogates so that emissions control is achievable and the data on which this is based must be subject to a rigorous quality assurance review.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Commenter Name: Sheila C. Holman

Comment Excerpt Number: 3

Comment: MACT standards are quantitatively based on available emission test data to calculate the MACT floors and set emission limits. The actual numerical values of the standards are sensitive to the particular set of emission data collected and treated for each subcategory and pollutant. Given the sensitivity, it is reasonable to expect that by now EPA would have defined some form of minimum available data quantity/quality requirements in establishing standards to assure their basis is sufficiently rigorous, accurate, and representative. EPA is quite experienced in setting quality assurance {QA) requirements for industry to meet for enforcing emission standards, but so far is hesitant in setting its own QA requirements to meet for developing emission standards.

Document Control Number: EPA-HQ-OAR-2002-0058-2913.1
Comment Excerpt Number: 3

Comment: We have grave concerns about the quality of data used to establish the MACT floors. A limited review by our industry of the data used to set the Boiler MACT standards identified errors in units of measure, fuel and boiler categorization, detection limit calculations and measurement techniques. Two of our company's thirteen power boilers that fall under the biomass subcategory in the proposed rule are subject to carbon monoxide (CO), mercury and dioxin/furan emission limits that are based on flawed data. Specifically. for that subcategory the CO limit is based on best performer data from a suspension burner that was misclassified as a stoker; the mercury limit is based on a best performer that did not observe the necessary EPA Method 29 testing procedures; and the dioxin/furan limit is based on a mishandled toxic equivalency quantity calculation that results in an emission rate that is an order of magnitude too low. We find it profoundly disturbing that a rule which impacts not only select sources within our own company but also the entire breadth and depth of the nation's manufacturing sector's steam and power generating units establishes emission limits based on data that has such glaring quality deficiencies.

Comment Excerpt Number: 4

Comment: EPA's rush to comply with the unrealistic rulemaking schedule it agreed to in the IB MACT rulemaking has resulted in obvious and multiple flaws in the proposed MACT standards. EPA does not appear to have conducted its own quality assurance analysis of the ICR stack testing data. As UARG describes in its comments, even a cursory review of the IB MACT data by its consultant has revealed several important problems with EPA's analysis of the ICR data.

The fact that UARG was able to identify such obvious errors in a very limited review of the IB MACT database raises troubling questions about EPA's apparent blind acceptance of the IB ICR data given time limitations. EPA needs to conduct a thorough quality assurance review of the IB ICR data and only after that review repropose IB MACT limits.

The lesson for the upcoming EGU MACT rulemaking is that EPA must conduct a thorough analysis of the information it receives from its EGU ICR request. If more time is needed for EPA to perform a proper review, it must ask the court to revise the rulemaking schedule.

Document Control Number: EPA-HQ-OAR-2002-0058-2798.1
Comment Excerpt Number: 4

Comment: The language in the Proposed Boiler MACT preamble is silent on EPA's use of any QA requirements applied to set subcategory emission standards. Interestingly, EPA requested comments on other related data quality issues in setting emission floors, including:
1. Approaches suitable to account for measurement variability in establishing the floor emission limit when based on measurements at or near the method detection level (MDL).
2. Whether there is a more appropriate approach to account for variability in the MACT floor analyses when there are emissions data from a limited number of units in the subcategory.
3. Whether EPA should consider reading the intent of the CAA to allow consideration of 5 sources rather than 12% when there is a source category with greater than 30 sources, but the EPA only has data for less than 30 sources.
Data presented in Tables 2 and 3 of the Proposed Boiler MACT can be used to show the percentage of the population (sources) with data used to set standards ranges from as little as 2% to as high as 63% with an overall average of 27%. The average (27%) and high (63%) population coverage values appear adequate in providing a quantitative rationale to serve as a reliable basis as sufficiently robust, accurate, and representative for standards setting. However, the low {2%) and other single-digit percentage values (for five of nine dioxin emission category standards and for four of the five pollutant standards for the Other Gases Subcategory) do not provide an adequate quantitative rationale for reliable standards setting.

Comment Excerpt Number: 5

Comment: When the NC Attorney General directed DAQ to proceed with the 112(j) process for emission standards and permitting, we began by examining emission data from our sources and the corresponding national database available to EPA at that time. In that examination, we came across some cases where the EPA database did not match our data for the same NC tests in terms of fuel use. For example, EPA mis-categorized a multi-fuel permitted facility emission test data while firing natural gas in the liquid oil data category. We did not retain nor use the EPA data points that were mistaken since our examination of the EPA database was not exhaustive. In other words, the correction of those points would simply mean that those points would be corrected. There was no guarantee the rest of the EPA data would be correct because we only had authority to review our data. As a result, we limited our inquiry to NC data that we reviewed and quality assured (QA'd). Given DAQ had already QA'd data, we consider it EPA's responsibility to likewise QA its handling of our data without our re-review. Given the limited comment period provided on the Boiler MACT proposal, it was not possible to carefully QA the NC emissions data base used by EPA.
EPA must conduct a thorough review of the emission database, fix flawed data, and then recalculate the MACT floors and associated proposed standards.
Rather than wait until parts of the rule are challenged on insufficient available data-related issues, NC DAQ suggests EPA develop and use a set of data QA requirements and standard operating procedures (SOPs) upon which more defensible emission standards can be established.
The data set QA requirements and SOPs should include:
Independent third-party QA review of EPA emission database,
Minimum quantity of sources with data necessary to set a valid floor,
Minimum percent of affected source population with data necessary to set a valid floor,
SOP for treating MDL data in lieu of otherwise valid data, e.g., raising values that are below the MDL to 3-times the MDL.
SOP for handling data at or near the MDL.
SOP for handling CEMS data.
SOP for setting the floor where there are data for less than 30 affected sources, but where the affected source population exceeds 30 sources.

Comment Excerpt Number: 6

Comment: EPA's rush to comply with the unrealistic rulemaking schedule it agreed to in the IB MACT rulemaking has resulted in obvious and multiple flaws in the proposed MACT standards. EPA does not appear to have conducted its own quality assurance analysis of the ICR stack testing data. Even a cursory review of the IB MACT data by RMB Consulting revealed [see submittal for memo.] several important problems with EPA's analysis of the ICR data.

For example, EPA identified the ASEA Boiler No. 1 owned and operated by Archer Daniels Midland as the best performing coal-fired unit with respect to PM emissions. EPA reports filterable PM emissions for this unit of 0.0002 lb/MBTU. An examination of the test report shows that filterable PM using Method 29 is reported as 0.0002 lb/MBTU, but the report also lists filterable PM2.5 emissions of 0.0096 lb/MBTU. These results make no sense because filterable PM2.5 emissions are a subset of total filterable PM emissions. At least one of these two values must be incorrect. The total filterable PM value of 0.0002 lb/MBTU seems more suspect because that level of PM emissions is (1) unprecedented in a coal-fired boiler and (2) at or below the quantification level of a gravimetric method, even for a 4-hour sampling run.

A second example is Dominion Generation’s Possum Point Power Station auxiliary boiler No. 1. EPA identifies that unit as the 11th best performing oil-fired unit with regard to carbon monoxide (“CO”) emissions. However, the test report clearly states that the Dominion unit only fires natural gas. The unit does not belong in the liquid fuel subcategory, much less as a best performing unit that is used to set the MACT floor for that subcategory.

A third example is the unit identified as the best performing oil-fired unit for CO emissions -- the No. 4 Vaporizer at the DAK Americas plant in Moncks Corner, South Carolina. The narrative section of that unit’s test report states that the CO concentration was essentially zero throughout the test runs. EPA used an average CO concentration of 0.0515 ppm [The number of significant figures reported by EPA indicates a level of scientific certainty that finds no support in the test report.] for its analysis of this unit’s test data. RMB Consulting’s examination of the raw, 1-minute CO data revealed that at least half of the values were negative concentrations, suggesting either zero drift and/or calibration issues. RMB Consulting also observed that the CO analyzer was operated on a 0 to 500 ppm range and was calibrated with cylinder gases having concentrations of 231 and 484 ppm. In order to make credible measurements at the extremely low levels reported, the CO analyzer should have been operated on a 0 to 10 ppm range with a nominal calibration gas concentration of 5 ppm. The low-level CO concentrations reported are simply not credible given the way the CO analyzer seems to have been operated.

The fact that RMB Consulting was able to identify such obvious errors in a very limited review of the IB MACT database raises troubling questions about EPA apparent blind acceptance of the ICR test data given time limitations. This rush to use the ICR data without thorough review and analysis is exactly the problem UARG envisioned when it challenged the consent decree schedule EPA agreed to follow in the EGU MACT rulemaking. EPA needs to conduct a thorough QA review of the IB ICR data and only after that review repropose IB MACT limits.

The lesson for the upcoming EGU MACT rulemaking is that EPA must conduct a thorough analysis of the information it receives from its EGU ICR request. If more time is needed for EPA to perform its legally mandated obligations under the CAA, then it must ask the court to revise the rulemaking schedule.

Comment: Within these severe time constraints, we conducted a spot check in order to assess the quality of the data the Agency relied upon in calculating the MACT floors that underlie the proposed rule.

This spot check revealed numerous data errors – many of which, if corrected, would have a material impact on the stringency of EPA's calculated MACT floors and associated proposed standards. To name just a few, there was: (1) widespread inconsistency in the data reported under the Phase I and Phase II ICRs, such as entirely different methods of determining and reporting "non detects"; (2) inconsistent reporting of dioxin/furan emissions testing results;
(3) inconsistent and incompatible PM emissions testing methods; and (4) mischaracterization of boiler types, such as including a coal-fired boiler in the biomass subcategory. The number and magnitude of the errors provide clear evidence that the database is fundamentally flawed and that any standard derived from the database does not have adequate factual support.

To resolve this problem, RMA recommends that EPA conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for public comments (including sufficient time for commenters to conduct their own comprehensive review of the data).

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Comment: EPA has placed several GP boilers in the incorrect category.
(i) Unit WIGPGB10 is not a liquid boiler
The WIGPGB10 (GP's Green Bay Broadway Boiler 10) unit listed in Appendix
C-4 of the Memo shows this unit as a liquid-fired boiler. This boiler burns secondary fiber deinking residuals to produce steam for the secondary fiber papermaking process. Secondary fiber deinking residuals are biomass fuel consisting of recovered fiber from the deinking process that cannot be made into paper. Therefore this unit should be included in the biomass category.
(ii) Unit LAGPort Hudson is not a biomass boiler
The LAGPort Hudson - EQT0109 No. 6 CFB unit listed in Appendix C-4 of the Memo shows this unit as being in the MACT floor and a biomass boiler. This boiler burns more than 10% petroleum coke along with biomass and natural gas to make steam for the papermaking process. The probable reason for this boiler
being mischaracterized is that during EPA's Phase I Information Collection Request (ICR) there was no choice in the drop down menus for petroleum coke and the instructions told responders to select coke oven gas instead. Therefore, this boiler should be in the coal category since it burns more than 10% petroleum coke.
(iii) Several other GP units are also mischaracterized as burning coke oven gas The following boilers also have been listed as burning coke oven gas when in fact they burn petroleum coke:

GASRMRincon – EU B002
This boiler is incorrectly listed in the Gas 2 category but should be listed in the coal category because it burns 100% petroleum coke and does not burn coke oven gas (as described above).
GASRMRincon – EU B003
This boiler is correctly listed in the coal category and burns a combination of coal and petroleum coke, but does not burn coke oven gas (as described above)
GASRMRincon – EU B001
This boiler is correctly listed in the coal category and burns a combination of coal and petroleum coke, but does not burn coke oven gas (as described above)
WIGPGreen Bay0218 – B29-Fluidized Bed Boiler #9
This boiler is incorrectly listed in the Gas 2 category but should be listed in the coal category because it burns 100% petroleum coke but does not burn coke oven gas (as described above).
EPA should correct the above errors in its database. This information was communicated to Brian Schrager, U.S. EPA in a letter via email dated 6/24/2010 and included in the submittal Appendix A – Communications with EPA.

Response: The specified data corrections have been processed in the EPA database.

Comment: EPA has incorrectly listed particulate matter and mercury emissions for GAGPBrunswick – No. 4 Power Boiler.
The GAGPBrunswick – No. 4 Power Boiler unit listed in Appendix C-4 of the Memo shows this unit as being in the MACT floor for filterable particulate emissions of 0.0005 lb/MM Btu (test date 8/5/2009), but this value is actually for the “filterable <2.5 um fraction” from the OTM 27 test. The correct value for filterable PM for this test 0.00602 lb/MM Btu. Also, for mercury listed in Appendix C-5 of the Memo (test date 4/28/2006) EPA shows an incorrect value – the correct value should be 6.05E07. In the same table, EPA shows duplicate values for the August 2009 test results (one should be deleted).
EPA should correct these errors in its database. This information was communicated to Brian Schrager, U.S. EPA in a letter via email dated 6/23/2010 and included in Appendix A – Communications with EPA.

Response: The specified data corrections have been processed in the EPA database.

Comment: Particulate matter data from GP's Brewton Mill is incorrectly presented in the Memo EPA has incorrectly listed data from unit ALGPBrewton Mill – BR-SPGO-S026 No.3 Power Boiler as 12 individual runs. This boiler has two stacks designated as North and South. On 12/12/2007 and 7/11/2008 the mill performed stack testing for particulate matter on each of the stacks. Therefore, the correct emissions from this boiler are determined by adding the emissions from each stack to get the total emissions from the boiler. The submittal includes Table 13 which shows the correct calculations for the two tests in the "Combined" stack rows. The full test report will be made available to the Agency upon request.

Response: The specified data corrections have been processed in the EPA database.

Comment: EPA has incorrectly listed particulate matter emissions for GAGPMadisonPly – 800 Wood Waste Boiler.
This unit listed in Appendix C-4 of the Memo shows this unit as being in the MACT floor for filterable particulate emissions of 1.17E-03 lb/MM Btu (test date 8/1/2009), but this value is actually 1.21E-03 after correcting Sample Run #2 for the actual mass of particulate collected. EPA should correct this error in its database. This information was communicated to Brian Schrager, U.S. EPA in a letter via email dated 6/22/2010 and included in Appendix A – Communications with EPA.

Response: The specified data corrections have been processed in the EPA database.

Comment: EPA has incorrectly listed mercury emissions for VAGPBigIsland – PWR05 – No. 5 Power Boiler.
Although this unit is not listed as being in the MACT floor, Version 5 of EPA's database has an incorrect value for mercury emissions. In the 5/2/2007 test report mercury fractions 3A and 3C were not collected and analyzed nor were the mercury results corrected for blanks.
EPA should delete this test result from its database. This information was communicated to Brian Schrager, U.S. EPA in a letter via email dated 6/22/2010 and included in Appendix A – Communications with EPA

Response: The specified errors have been noted in the EPA database and the data will not be used in future analyses.

Comment Excerpt Number: 23

Comment: EPA has incorrectly listed particulate matter and mercury emissions for ORGeorgiaPacificWaunaMill – Fluid Bed Boiler.
This unit, listed in Appendix C-4 of the Memo, is shown in the MACT floor for filterable particulate emissions of 5.80E-04 lb/MM Btu (test date 7/19/2009), but this
value could not be matched with any of the emissions data in the test report. The 7/2009 test report does include the following two correct Method 5-based PM filterable tests: a Method 5/Method 29 test conducted for metals except for mercury ('M5/M29 without Hg') with a value of 2.39E-04 lb/MM Btu, and a Method 5/Method29 test conducted for mercury only ('M5 with Hg') with a value of 4.25E-04 lb/MM Btu.
Although this unit is not listed as being in the MACT floor for mercury, Version 5 of EPA's database has an incorrect value of 7.62E-07 lb/MM Btu for mercury emissions. In the 7/2009 test report mercury fraction 3A was not collected and analyzed nor is it clear that the detection limit reported by the laboratory is consistent
with EPA's Guidance Document 51F. Therefore, EPA should delete this mercury value from its database
EPA should correct these errors filterable PM emission and delete the mercury data from its database. This information was communicated to Brian Schrager,
U.S. EPA in a letter via email dated 6/29/2010 and included in Appendix A – Communications with EPA.

Response: The specified corrections to the filterable particulate data have been made. The specified mercury errors have been noted in the EPA database and will be excluded from future analyses.

Comment: The data in the US EPA's Boiler MACT Emissions Database for Boilers and Process Heaters Containing Stack Test, CEM, & Fuel Analysis Data Reported under ICR No. 2286.01 and ICR No. 2286.03 (version 5) has not been adequately peer reviewed and is too flawed to base calculation of MACT standards

Ameren reviewed the stack test data in the database for the liquid fuel and gas fueled subcategories and found several instances of poorly reported or obviously erroneously reported data used to develop MACT floors. It was also found that the boilers used to establish the MACT floors were not representative of the boiler population as a whole and should not be used to establish MACT standards for the subcategory. The issues with the reported data used to establish the MACT floors are detailed below.

The Conemaugh Plant in New Florence reported a PM sample run (no. 2) which is 1/4 the value of other 2 runs and appears to be an outlier.

The Milan Army Ammunition Plant in Tennessee reported data from a boiler less than 15 MMBtu/hr with no control and this data was used to establish MACT floor for PM and Hg as a best controlled source. The PM data included a non-detect value which indicates a problem with the stack test run. The data for Hg was based on several fuel sample analyses even for a single source at the plant but a Hg stack test of that source was not performed and the source could therefore not be in the best controlled 12 %. The source is uncontrolled burning diesel fuel and the HG floor and variability analysis utilized 29 fuel sample data points at reported at below the same method detection limit. This data skews the variability analysis as it encompasses almost half of the data used to establish variability. The dioxin/furan data from this source was not used to establish the floor but also appears to be flawed as the source reported no detection limits even though the data ranked no. 4 and the 3 sources ranked ahead were all reported as DLL and all but one source after it reported dioxin/furan results as BDL or DLL except 1 (out of 17 boilers).

The GP plant in Green Bay Wisconsin reported PM values for a boiler rated at 95 MMBtu per hour firing wastewater sludges. This source should not be used to establish MACT floor for sources firing fuel oils because based on the definition proposed for solid wastes, no other facility could utilize the sludges from this plant as a fuel without being subject to the incinerator MACT. Additionally, the US EPA selectively chose the lowest test out of three from this source. If the US EPA is going to utilize test data from a source to establish a standard, it must use all stack test data from that source.

The Cherokee Pharm plant in Pennsylvania was used to establish the PM MACT floor based on a 1998 test burning a combination of NG and fuel oil with no indication of the relative percentages of each. US EPA needs to establish that the majority fuel was not NG or at least establish the relative percentages of fuels. Ameren believes that it is improper for the MACT floor for liquid fuels to be based on source test which utilized any amount of NG or other gaseous fuels as they will bias the results and are not reflective of liquid fuel fired boilers. In addition, the source reported both the filterable and total PM as the same value. This is obviously an error and may indicate under reporting of total PM or over reporting of filterable PM.

The Milliken plant in Dewey, South Carolina was used to establish the PM, Hg, HCL and dioxin/furan MACT floors. The data from this plant is based on a boiler burning Anhydrides Waste in a boiler rated at 10.5 MMBtu/hr. No other facility in the nation could utilize this fuel, and as a result, it is improper to utilize the results from this facility as a basis for establishing MACT standards for the entire country. The boiler is uncontrolled and obtains the maximum degree of emission reduction solely by virtue of burning a byproduct fuel which is unavailable to all other facilities. The data from this plant should be put into an “other/byproduct fuels” subcategory which establishes limits for non-petroleum based fuels. In addition, the information in the database indicates the particulate results used to establish the MACT floor were based on method OTM 27 which measures PM10 or PM2.5 emissions even though the data was reported as PM. The results of the particulate fractions testing are being compared against sources who are reporting PM filterable data based on US EPA method 5 and is therefore biased low. This testing methodology is different than that required under the standard, results in biased low data and is also different than all other methods used to establish the PM MACT floor and therefore should be excluded from the analysis.

The GP plant in Duluth, MN was used to establish the Hg floor based on data from a boiler rated at 43 MMBtu/hr and firing #6 fuel oil with no controls. The stack test data indicates that the results are below detectable limits.

The FPL Energy Wyman Plant in Maine is a 72 MMBtu/hr #6 fuel oil fired boiler without controls used to establish the MACT floor for Hg even though the Facility reported relatively high PM emission rates while simultaneously reporting very low Hg. Fuel samples taken during the test resulted in Hg levels on the order of 10-5 #/MMBtu and stack test results were on the order of 10-8 #/MMBtu. This is a loss of 99% of the Hg in the fuel at the stack in a unit with no controls. Detection limit values were not reported and because reported levels are at or below the limit of detection for other tests, it is likely the values are representative of method detection limits and not actual detections of Hg in the stack samples. Because Hg disappears into the ether between the fuel and stack and the suspect manner for which the data for Hg is from stack test is reported, the use of this data is suspect. US EPA should not use data from this Facility for establishing the MACT floor without a thorough quality assurance analysis of the data. Additionally, the US EPA appears to have erred by using the stack test data from this plant and multiple fuel analysis data points from this Facility. In essence, even though the US EPA had fuel variability data from this source, it ignored that data potentially due to the very high Hg values reported. If US EPA is going to maintain that this source is a top performer for Hg, it must use the fuel variability data collected from this source to establish the UPL as it has done with other sources in the top 12 %.

The Cognis plant in Il Boiler 1 is a 67.3 MMBtu/hr boiler burning bioliquids and NG with no controls. Because the biofuels which put this unit in the liquid subcategory are not available at other facilities, it is inappropriate to utilize this facility's boiler emission data for the MACT floor analysis for sources burning commercially available petroleum liquids. Other problems with use of data from this Facility include that the MACT floor includes data from both Boiler 2 and Boiler 1 at the Facility as separately ranked sources even though only one boiler was tested (Boiler 1) and the values for ranking are based on the fuel sample analysis for the boilers. The sample analysis, however, is not representative of the fuel combusted in the boiler as the boilers are dual fuel as they combust a mixture of the bio liquid and NG. The sample data is only representative of the liquid portion of the fuel and is therefore not representative of stack emissions. Because the fuel sample analyses were ND, both values for Boiler 1 and Boiler 2 were the same, resulting in the same ranking for both units. This is improper for establishing the MACT floor. MACT floor data needs to be based on stack test data because it must represent the "maximum degree of emission reduction achievable". Basing the MACT floor on a combination of stack and fuel sample data is not representative of the degree of emission reduction which is achieved from any combustion controls and is therefore biased. Additionally, the animal fats liquid fuel tested has a relatively high higher heat value and is therefore prone to obtaining lower detection limits from fuel sampling on #/heat input basis. This biases the BDL results from this Facility falsely indicating the Hg may be lower relative to other sources then it actually is on a heat input basis.

The Boeing facility in Ridley Park, Pennsylvania tested a 42 MMBtu/hr boiler burning #6 fuel oil with no controls. All results from these tests were non-detect and this boiler ranked as achieving the maximum degree of emission reduction achievable based on the low Hg detection limits during the stack test of this unit.

The Consolidated Edison 59th St. Station in New York, NY is a 180 MMBTu/hr boiler burning No. 6 fuel oil with a fabric filter and sorbent injection controls. This Facility reported Hg emissions as above detection limit values at the level of 0.15 #/tBtu. This is an order of magnitude lower than normal detectable levels of Hg and is therefore suspect.

Ameren believes this source may have incorrectly calculated the method detection limits for the testing performed.

The SD Warren plant in Somerset, Maine was used to establish the Hg floor for Hg. The US EPA indicates in a Table in appendix C-2 to the memorandum on the MACT floor analysis that test data from a Package boiler at the site was used to establish the MACT floor. Based on appendix C-5, the data is from fuel testing of mixed fuels at the site. However this data is not available in the emissions database in the docket and does not correspond to any emissions testing at the facility. In other reporting for the site, the source reported non detect data at 1/2 the method detection limit. This is contrary to the instructions for reporting in the ICR and as a result all data from the facility is suspect and should be thoroughly quality assured. In addition, US EPA should not be using data not reported in the emissions test database for the docket. The data can not be adequately reviewed and commented upon without seeing the unadulterated data prior to US EPA manipulations.

The Electric Boat facility in Connecticut reported Hg data on EMU 17 which is a 7 MMBtu/hr boiler reportedly burning no. 4 fuel oil with no air pollution control equipment. The source is not large enough to even consider for the proposed source category which is boilers > 10 MMBtu/hr, is not, and cannot be representative of the emissions from larger boilers on the order of hundreds of MMBtu/hr. In addition, the source indicates that four (4) hg runs were performed based on test run numbering; however, one run was not included in the database. The Facility also provided data on a single fuel sample (Sample 1) which was attributed to two emission units and that single sample analysis was used twice to establish the MACT floor. The MACT floor should not include data from the Electric Boat facility as it is not representative of source category and the misreported data needs to be deleted from the database. This source was also included in the MACT floor for dioxin/furan testing. Because of its size it should not be used to establish the MACT floor for D/F.

The US Steel Gary Works in Indiana reported Hg emissions from a 500 MMBtu/hr boiler with no controls burning 13 % fuel oil and 87 % blast furnace gas and natural gas. This source is not representative of the liquid fuels subcategory as it is primarily fueled using by-product gases. In addition, the fuel testing of the fuel oil during the test indicates that No. 4 fuel oil was sampled and analyzed, however, test data indicates that No. 6 fuel oil was burned. This discrepancy and the fact that liquid fuels are not the primary fuels should disqualify the data from this source from being used to establish the MACT floor.

Response: The specified corrections have been made to the EPA database.

Comment: The file size for Version 5 of the database is about 110 MB. It contains 44,389 records with emission test results; 92,822 records with fuel analysis information; and 44,219 records with CEMS data. ACC is concerned that the data has not been thoroughly checked by EPA and its contractor for accuracy.

Over the past several months, ACC and its member companies have examined stack test reports and associated laboratory analysis reports for filterable PM, HG, HCl, dioxin/furan, formaldehyde, and/or total hydrocarbons (THC). There are a disturbing number of problems with the test results appearing in the Version 5 database and it is obvious the test results being used to develop the proposed emission limits have not received an adequate review. ACC has communicated the errors and problems to EPA, and our members have submitted requests for data corrections to EPA, yet in many cases the errors and problems remain unresolved. Some of the problems identified, when corrected, will have a dramatic impact on the proposed emission limits.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Comment: EPA has incorrectly listed mercury emissions for MNGP Duluth EU 33 Boiler #3 is listed in the database memo (Table C-5) as a best performer for mercury. In the test report performed on 9/10/2009, the reported mercury fractions have been calculated with non-detect fractions being treated as zero instead of at the method detection limit (MDL) as requested in EPA's Guidance Document 51F. GP is aware of conversations between NCASI and EPA in which the Agency requests that the Reporting Detection Level (RDL) should be reported. NCASI has recalculated non-detects at the RDL which results in an emission level of 1.05E-07. EPA should correct this test result in its database. This information was communicated to Brian Schrager, U.S. EPA in a letter via email dated 8/19/2010 and included in Appendix A – Communications with EPA

Response: The specified data corrections have been processed in the EPA database.

Comment: Given the limited comment period that has been provided on the Proposed Rule, it simply has not been possible to conduct a thorough data quality assessment on EPA's entire emissions data base. EPA's failure to provide adequate time for an appropriate assessment of the data violates the agency's obligation to provide a full and fair opportunity for public comment on the proposed rule. Within these severe time constraints, industry representatives conducted a spot check of 100 stack test reports and associated information from top performers in order to assess the quality of the data the agency relied upon in calculating the MACT floors that underlie the proposed rule.

This spot check revealed numerous data errors – many of which, if corrected, would have a material impact on the stringency of EPA's calculated MACT floors and associated proposed standards. To name just a few, there was: (1) widespread inconsistency in the data reported under the Phase I and Phase II ICRs, such as entirely different methods of determining and reporting "non detects"; (2) inconsistent reporting of dioxin/furan emissions testing results; (3) inconsistent and incompatible PM emissions testing methods; and (4) mischaracterization of boiler types, such as including a coal-fired boiler in the biomass subcategory. The number and magnitude of the errors provide clear evidence that the database is fundamentally flawed and that any standard derived from the database does not have adequate factual support.

To resolve this problem, EPA must conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for public comments (including sufficient time for commenters to conduct their own comprehensive review of the data).

Response: EPA has made substantial revisions to the database since the proposal. These revisions have been based on specific corrections to data and additional data submissions received since the proposal. These substantial changes are discussed in the January 2011 memorandum from Graham Gibson, ERG, to EPA entitled "Handling and Processing of Corrections and New Data in the EPA ICR Databases".

Comment: As our members and other organizations review the data underlying EPA's proposed rule, we continue to identify notable errors that renders the data utterly unreliable and thus in violation of Clean Air Act standards. This include errors in fuel and boiler categorizations, errors in calculation of detection limits, errors in measurement techniques that render test results invalid, and others. Fundamentally, failure to correct such data errors will result in arbitrary and capricious rulemaking.

Errors have been found in data from sources that EPA has identified as "top performers." Errors in "top performer" data is particularly problematic, because that data are the foundation for EPA's calculation of MACT floors that will apply to all sources in the same subcategory emitting that pollutant. Specific examples of such data errors are specifically detailed in comments by others, but include: a top performer in the Gas 2 subcategory actually burns petroleum coke and not coke oven gas; the CO limit for biomass stoker boilers was based on top performer data from a suspension burner that was misclassified as a stoker; the dioxins/furans limit for biomass stoker boilers and coal fluidized boilers was based on data that had been reported on a Toxic Equivalency Quantity (TEQ) basis and was mistakenly corrected to its TEQ value a second time, resulting in values an order of magnitude lower; the Hg limit for biomass boilers was based on data that did not follow the required Method 29 procedures, where the source has recently asked EPA to remove data from the database.

To resolve this problem, EPA must conduct a thorough review of the database, correct or eliminate the flawed data, recalculate the MACT floors and associated proposed standards, and provide a new opportunity for public comments (including sufficient time for commenters to conduct their own comprehensive review of the data). Finalizing the proposed standards with these underlying errors would render the standards immediately indefensible. See e.g., Columbia Falls Aluminum Co. v. EPA, 139 F.3d 914, 923 (D.C. Cir. 1998) ("An agency's use of a model is arbitrary if that model "bears no rational relationship to the reality it purports to represent.").

Comment: Liquid Fuel Mercury (GP Duluth - MN - EU33 Boiler #3) – The unit is listed as having a common stack for the one liquid fuel unit and two biomass fired units. The mercury testing says it was at the stack. If that is the case, this is not valid data unless the other two boilers were shut down or isolated in some way or the testing was done somewhere before the mix-point.

Response: An independent review of the data by the National Council for Air & Stream Improvement (NCASI) resulted in submittal of corrected mercury data points for this boiler. Those corrected data points have been processed in the EPA database.

Comment Excerpt Number: 30

Comment: Other Gas Firing CO (Shell Chemical Geismar - LA - Furnace F-S801) –There are three data points not included in the average because the 10% fuel is listed as Gas-1. This may be an error. The percentage of Gas-1 in those points is 23.9, while it is 32.8 in the test points included. Why would the points with the lower NG firing not be included? Inclusion of these points would increase the average from 0.0129 ppm at 3%02 to 0.055 ppm at 3 percent O2.

Response: The specified data corrections have been processed in the EPA database.

Comment Excerpt Number: 30

Comment: Errors in EPA's data set and its calculations are evident throughout the spreadsheets it has provided. These errors draw into question the accuracy and appropriateness of the MACT floors proposed by this rulemaking. When setting a standard that will cost industry millions of dollars to comply, precision is critical. Even a few transcription errors can result in significant changes to the proposed emission limits. EPA's failures in this regard have resulted in a proposal that is inappropriate, erroneous and unattainable.

Due to these and other likely problems in the data and math that form the foundation of this rule, EPA should reexamine its data, ensure its accuracy, and employ a more representative metric for ranking the sources and identifying the top performers.

Comment: Other commenters have already highlighted certain clear issues with the data set, and U.S. Sugar incorporates those comments by reference here. See, e.g., Consolidated Edison's August 3, 2010, comment that Table 2 of Appendix C-2 identifies 80 individual boilers at one facility with identical chlorine emission values, an outcome which is nearly statistically impossible. The numerous "#DIV/0!" errors appearing throughout the spreadsheet is also suggestive of a careless approach to the calculation process. Additionally, U.S. Sugar can point out several other specific problems in the data and calculus.

Comment: C. A review by American Petroleum Institute (API) on the data being used to set the MACT limits reveals numerous errors, including errors in fuel and boiler categorizations, errors in calculation of detection limits, and errors in measurement techniques that render test results invalid.

Errors have been found in data from sources that EPA has identified as "top performers." The top performer data was the foundation for EPA's calculation of MACT floors. Examples of such data errors include: a top performer in the Gas 2 subcategory actually burns petroleum coke and not coke oven gas; the

dioxins/furans limit for biomass stoker boilers and coal fluidized boilers was based on data that had been reported on a Toxic Equivalency Quantity (TEQ) basis and was mistakenly corrected to its TEQ value a second time, resulting in values an order of magnitude lower; and the Hg limit for biomass boilers was based on data that did not follow the required Method 29 procedures.

It is imperative that errors in the floor setting database be corrected before any final emission limits are promulgated.

Comment Excerpt Number: 32

Comment: The problems are further exacerbated in those categories for which only one source is setting the MACT Floor. For example, in the dutch oven biomass category, only one source is utilized to determine the threshold for dioxin/furans. That source is emitting 0.16 ppm, while the only other two sources are emitting 9 and 17 ppm respectively. Such a disparity raises questions of accuracy, or, alternatively, suggests an outlier that should be disregarded from a statistical perspective. At a minimum, one boiler should not be the only standard for a rule that applies across all industries nationwide.

Response: EPA based the floor calculations on the top 12 percent of data available in each subcategory. There was ample time provided to submit additional data and EPA updated its calculations with new data received during the proposal. As noted by commenters, dioxin/furan formation and concentrations can vary. There were no other reasons provided to suggest elimination of this test and so this data was not removed as an outlier.

Comment Excerpt Number: 41

Comment: We note, however, that even with additional time to review information in the docket, HOVENSA has not been able to decipher data in the docket with the certainty needed to adequately comment on the proposal. In many cases, the information in the database
* Is not clear on what fuel or fuels are being combusted and in what proportions
* Does not contain long term or even short term data for heaters or boilers fired at rates above 10% residual fuel oil.
* Does not provide basic design or duty information for the heater or boiler
* Does not provide information about the facility that the heater or boiler supports
* Is often one time stack test data
* Is unclear as to what the data fields in the database mean

We would like to thank EPA for allowing an additional 45 days to submit comments on the proposed Boiler MACT rule. However, even with the additional time, HOVENSA did not have sufficient time to gather additional data in support of these comments. HOVENSA is continuing a data gathering efforts and intends to supplement these comments.

Comment: In one or more public forums, EPA staff acknowledged that it performed little, if any, quality assurance on the stack testing database. Even a cursory examination of EPA's IB MACT database verifies the absence of quality assurance. For example, EPA identified the ASEA Boiler No. 1 owned and operated by Archer Daniels Midland (ADM) in Des Moines, IA as the best performing coal-fired unit with respect to PM emissions. For this unit, EPA lists filterable PM emissions to be 0.0002 lb/106 Btu.[42 U.S.C. §7412(d)(1).,Table 3] However, when we examine the ADM test report, we not only find the 0.0002 lb/106 Btu value for PM from the Method 29 filter analysis, but we also observe that ADM reported average filterable PM2,5 emissions to be 0.0096 lb/106 Btu. Of course, filterable PM2,5 is a subset of total filterable PM emissions. For a well-controlled source like this ADM boiler, PM2,5 might be 50 to 60 percent total filterable PM emissions. However, there is no conceivable way to reconcile total filterable PM emissions being X50 times less than filterable PM2.5 — at least one of the two PM averages must be incorrect. Certainly, the 0.0002 value should be considered suspect because that measurement would (1) reflect an unprecedented PM concentration and (2) be at or below the quantification level of the gravimetric method, even for 4-hour sampling runs.

Comment Excerpt Number: 94

Comment: We felt the need to examine some of the underlying data that EPA used to support a CO emission limit of 1 ppm by volume for oil-fired units. A CO emission limit of 1 ppm certainly grabs your attention, especially when you realize that the national ambient air quality limit (NAAQS) for
CO is 9 ppm for an 8-hour average.[See 40 C.F.R., §50.8(a)(1).] We cannot identify or think any other instance in EPA's 40-year history where the Agency has proposed to set an emission limit that is considerably lower than a NAAQS, which in and of itself is protective of public health and welfare. [We recognize that in this rule EPA is proposing a CO limit as a surrogate for various organic HAPs and not to protect public health. Regardless, the comparison provides context for just how draconian some of the proposed emission limits are.]

EPA identified the No. 4 Vaporizer owned and operated by DAK Americas in Moncks Corner, SC as the best performing oil-fired unit with respect to CO emissions. According to the narrative in the test report, the CO concentration was essentially zero throughout the test runs. [Page 7-1, "Section 114 Boiler MACT Data Collection Test Program at No. 4 Vaporizer," report prepared by TRC Environmental Corp., Raleigh, NC, TRC Project No. 169023.] For its analysis, EPA used an average CO concentration equal to 0.0515 ppm (note the significant figures). We examined the raw (1-minute) CO data and observed that at least half of the values were negative concentrations, suggesting either zero drift and/or calibration issues. We also observed the CO analyzer was operated on a 0 to 500 ppm range and was calibrated with a cylinder gases having concentrations of 231 and 484 ppm, respectively. If one wanted to make credible measurements

in the range claimed by the test contractor, the CO analyzer should have been operated on a 0 to 10 ppm range with a nominal calibration gas concentration of 5 ppm. Given the way the CO analyzer appeared to have been operated, such low-level CO concentrations are simply not credible.
EPA identified Auxiliary Boiler No. 1 owned and operated by Dominion Generation's Possum Point Power Station as the 11th best performing oil-fired unit with respect to CO emissions. [Page 5, "NOx and CO Emissions Test Report for the Auxiliary Boiler Stack at the Possum Point Power Station," prepared by the Air Compliance Group, Roanoke, VA, Contract No. V8548.] The problem is, as the report clearly states, the Dominion unit only fires natural gas. The Dominion unit does not belong in the liquid fuel subcategory, much less the pool of MACT floor units.

Comment: Fundamental Flaws in the Emissions Database.
Although it has not been possible to conduct a thorough quality assessment of the entire EPA emission database, AF&PA has done a spot check of one hundred stack test reports. The spot check revealed numerous errors that may have affected the MACT floors and the stringency of the proposed emission limits. It appears that the database is fundamentally flawed, therefore calling into question the factual basis for the standards. The EPA should review the database and correct or eliminate the flawed data and recalculate the emission limits.

Response: See response for DCN EPA-HQ-OAR-2002-0058-2998.1, Excerpt Number 28.

Data Standardization Techniques

Comment Excerpt Number: 22

Comment: F-Factors for wood have been used to develop emission limits for boilers burning bagasse. In its MACT floor calculations for CO, EPA used the F-Factor for wood to develop emission rates in parts per million by dry volume (ppmvd), based on FSI's submitted stack test data. The FSI completed an F-Factor study for the Florida Department of Environmental Protection many years ago. This study demonstrated that F-Factors for wood are not applicable to bagasse fired boilers, and also demonstrated that no single F-factor was representative of bagasse firing. This again is due to the nature (variability) of bagasse fuel and bagasse boiler operation. The FSI has since then submitted actual CO data in ppmvd @ 3 percent oxygen (O2) for all stack tests, so it is not necessary to use an F-factor for conversion.

Response: EPA has replaced the initially reported data which was standardized using an F-Factor with the newly formatted data from the Florida Sugar Industry. As a result, there is minimal CO data from bagasse combustion in the EPA database which is standardized using an F-Factor.

Comment Excerpt Number: 49

Comment: 7. EPA required that sources use Method 19 to calculate pollutant concentration on a 'lb/mmbtu' basis. However, it appears that some of the sources performed the data conversion using actual heat input based on fuel consumption data. Also, many of the sources used the default F-factor values specified in Method 19. For sources that co-fire multiple fuel types, this could be problematic unless the sources conducted fuel analysis to accurately quantify the F-factor. Furthermore, for sources that reported emissions results as a concentration, EPA applied an average F-factor based on the Method 19 default values if multiple fuels were fired. In some cases, it appears that the F-factor was prorated according to the reported heat input of the various fuels while for others it appears as a straight average. The bias in the reported 'lb/mmbtu' number for not prorating the default values could be significant. For example, for units co-firing coal and natural gas it could be as high as +/- 5%. [Footnote: Assuming a blend ratio of 10% coal/90% gas, the bias would be +5%. Assuming a blend ratio of 90% coal/10% gas, the bias would be -5%.]

Response: EPA used the data provided by sources to the survey and incorporated site-specific corrections as they were received. There was not enough background data to review F-Factor calculations incorporated into all of the results provided to EPA.

Comment Excerpt Number: 50

Comment: In the ICR database, EPA corrected the reported values of CO and D/F TEQ to a standardized O2 concentration (either 3% O2 or 7% O2 depending on the pollutant) only if the O2 basis was provided in the raw data. However, for data that were reported without a specified O2 concentration EPA assumed the reported value to be 0% O2. This does not appear to be an issue for the Phase II data since EPA specified the required format of the data to be in units of "lb/mmbtu" or specified O2 corrected concentrations depending on the pollutant. However, this could be an issue for some of the Phase I data. A review of the biomass & coal data for HCl, HF, PM, and Hg shows that there are a number of units that did not include a reported O2 correction factor in the raw data. This could be a significant negative bias (20-30%) depending on the actual stack O2 concentration.

Response: The EPA database was investigated where a zero percent oxygen level was assumed for Hg, HCl, filterable PM, and CO. Individual tests with low standardized values were re-standardized based on the reported oxygen percentage, where available. The resultant numbers showed very little significant change between the standardized values using an assumed zero percent oxygen level and the standardized values using actual oxygen percentages. There is a significantly small subset of data with oxygen levels at and above 20 percent, with the majority of oxygen concentrations falling under 15 percent.

Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-2741.1
Comment Excerpt Number: 52

Comment: The MACT floor data contains at least several data sets where the emissions were reported with incorrect units of measure due to unit conversion problems. For instance, in the MACT floor data for CO for PC-fired units, all of the measurements for Duke Energy Tuscola (Units 1, 3, and 4) where the CO concentration in the ICR database is less than 1 PPM are incorrect due to unit conversion problems. A review of the ICR emissions test spreadsheet file shows that the source did not report the units of measure for certain tests. EPA had assumed that the correct unit of measure for these test runs was "PPB" rather than "PPM". EPA then converted these values to PPM in the database and used them in the emissions floor analysis. This resulted in reported data for these test runs that were three orders of magnitude lower than actual measurements. This error is especially critical because this unit was used to set the standard for CO for new PC-fired units. It also affects most of the data used to set the standard for CO for existing PC-fired units.

Response: The specified data corrections have been processed in the EPA database.

Rule Language Corrections

Rule Language: Definitions (existing)

Comment: Clarify definition of gas curtailment. Under applicable gas utility tariffs, DEP is required to switch to oil when certain conditions are met, generally when temperatures drop below a set trigger point. The rules' definitions should encompass all such conditions.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-3174, Excerpt Number 2 to view the response.

Commenter Name: Myra C. Reece
Commenter Affiliation: South Carolina Department of Health and Environmental Control
Document Control Number: EPA-HQ-OAR-2002-0058-2525.1
Comment Excerpt Number: 3

Comment: The proposed definition of "deviation" in 40 CFR 63.7575 does not establish guidelines to determine continuous compliance with limits and work practice standards in the proposed rule. The definition states a deviation is not always a violation. While we agree with this assertion, the EPA should clearly define when deviations become violations as the EPA has defined in previous rules such as 40 CFR 63 Subpart MM — National Emission Standards For Hazardous Air Pollutants For Chemical Recovery Combustion Sources At Kraft, Soda, Sulfite, And Stand-Alone Semichemical Pulp Mills, 40 CFR 63 Subpart LL — National Emission Standards For Hazardous Air Pollutants For Primary Aluminum Reduction Plants, and 40 CFR 63 Subpart DD — National Emission Standards For Hazardous Air Pollutants From Off-Site Waste And Recovery Operations.

Exceedance Of An Emission Limit Should Be Considered A Violation When Using A Continuous Emission Monitor (CEM)

An affected source required to use a continuous emission monitor (CEM) that fails to comply with an emission limit should be considered a violation even during startup and shutdown events. Continuous emission monitoring data obtained from best performing units, and used in establishing the standards, include periods of startup and shutdown. The EPA did not establish separate emission standards for these periods because startup and shutdown are part of routine operations and are being addressed by the proposed standards. There should not be discretion for what constitutes a violation when an affected source required to have a CEM fails to meet the specified emission limit.

Establish A Violation Threshold For Baghouse Detection Leak System Deviations

The EPA proposes an operating limit for units controlled by a fabric filter in 63.7530(b)(3)(iv). This limit applies to units which choose to demonstrate continuous compliance by using a bag leak detection system to be operated such that the bag leak detection system alarm does not sound more than 5 percent of the operating time during a 6-month period. In 63.7540(b), the EPA proposes that facilities report each instance as a deviation from the emission limit for each instance the facility did not meet an emission limit and operating limit. Because the EPA has stated that the use of the above-mentioned alarm system demonstrates continuous compliance, then any additional deviations above the allowed 5 percent of the operating time during a 6-month period should be considered violations.

Establish Violation Thresholds For Continuous Opacity Monitoring Systems (COMS) And Continuous Parameter Monitoring Systems (CPMS) Deviations

The EPA has established violation thresholds for operating limits for other section 112(d) source categories such as those found in 63.864(k)(2), 63.848(i), and 63.695(e)(5). This rule needs to clearly identify when boilers or process heaters are in violation of the standards when operating parameters used to demonstrate continuous compliance are not met. Also, the EPA proposes the use of continuous opacity monitoring systems (COMS) and continuous parameter monitoring systems (CPMS) for certain affected boilers and process heaters to demonstrate continuous compliance with the proposed standards. The rule needs to include a percentage of time during a 6-month period that these continuous monitoring systems (CMS) are required to be operational and meet any operating limit in order to determine compliance.

Comment Excerpt Number: 5

Comment: Definitions- Boiler and Hot Water Heater
The definition for hot water heaters does not adequately distinguish between residential-type units and industrial/commercial/institutional units. It is clear in the Preamble that the intent is to include institutional boilers. To clarify, it is suggested additional language to the hot water heater definition be added to include “for domestic hot water use”. Penn State does have hot water heaters that are above the 120 gallon threshold but do not exceed 160 psig or 210 °F. It is unclear if these devices are exempt or if they are considered boilers using the broad boiler definition. If they are considered boilers, then the tune-up requirements would apply and adds to the large number of units subject to the work practice standards of biennial tune-ups.

Comment: Definition of Unit Designed to Burn Oil overly restrictive

Purdue University’s Boiler #3 is a natural gas fired unit that can also burn oil. Because Purdue’s utility plant is the only source for campus heating steam, the availability of fuel for emergencies is paramount. For Purdue’s Boiler #3, fuel oil is only used when a natural gas curtailment order is in effect, or for training and testing. Boiler #3’s annual use of fuel oil over the last 10 year period is as follows: average use 2,130 mmBtu/yr, 1-year peak use 7,124 mmBtu/yr. The unit cost of firing fuel oil is $17.16/mmBtu with natural gas at $6.26/mmBtu at the current market price for oil. At 2.7 times higher than natural gas, there is no economic driver to use oil over natural gas. However, the ability to fire oil if necessary is retained to ensure delivery of steam to campus even if natural gas were not available.

The proposed rule definition of “Unit designed to burn oil subcategory” (§63.7575 page 32065) reads:

Unit designed to burn oil subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent solid fuel on a heat input basis on an annual average, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year are not included in this definition.

This definition would categorize Purdue’s Boiler #3 as a liquid fired boiler even though it runs only several days per year on oil and only out of necessity. The substantial cost of compliance with performance requirements for the oil fired subcategory is incredibly burdensome for a unit that fires natural gas nearly all of the time. This unit also meets the definition of “Unit designed to burn gas 1(NG/RG)”. Purdue requests that EPA consider modifying the definition of Unit designed to burn oil to include only units that burn more than 10 percent on a heat input basis of oil and eliminate the qualifier “any” from the “Unit designed to burn oil” definition.

Comment: Definitions - Units designed to burn oil category
The 48 hour limit within the definition for units designed to burn oil subcategory contradicts the definition for units to burn gas 1 definition. A unit is designated as a gas unit if it burns 90% natural gas on a heat input basis. Oil would be the backup during periods of gas curtailment or gas supply emergencies. It can be interpreted that once the 48 hours is reached, the unit becomes an oil unit and then the limits for an oil unit would apply. 48 hours is a short and arbitrary time period and is a much stricter parameter than the 90% heat input limit. Periods of gas curtailment or supply

emergencies are outside the control of the facility and should not count against the facility regardless of the length of time it occurs.
One of the options available to the University to meet Boiler MACT is to switch to firing only natural gas. For reasons of reliability and safety, an on-site source of backup fuel will be required. The logical choice is fuel oil. As currently stated, the University's boilers will become "liquid fuel fired units" after firing fuel oil for just 48 hours per year. Training and testing alone would require at least two days per calendar year leaving no time allowed for emergencies and curtailments, the reason for having fuel oil back up. A resolution similar to the recently published RICE MACT would better address the needs of the University. That rule incorporates an understanding that emergency conditions are in addition to hours used for testing, training and other non-emergency matters. Or, the Administrator could adopt the definition of "gas-fired boiler" as given in the Area Source Boiler MACT.

Response: EPA has revised the definition in the final rule to exclude gas curtailment periods and gas supply emergency periods from the 48-hour limit on liquid fuel combustion at gas units. EPA has also added that curtailments and emergencies could be of any duration.

Comment: The definition of "coal" in the section 112 major source rule includes "coal refuse." Coal refuse is defined as coal wastes that have ash content higher than 50 percent and heat value of less than 6000 BTU. The rule then sets out that it applies to units that combust "coal." However, units that combust coal refuse with those properties may well be subject to section 129 limits. EPA should correct the definition to avoid any confusion on this issue.

Comment: The definition of natural gas needs to be revised to match recent definition changes to include gases (such as treated landfill gas and synthetic natural gas) that are not from geologic formations.

EPAs' proposed definition of natural gas reads (in part) as follows:

Natural gas means (1) a naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane.

On January 28, 2009, EPA finalized natural gas definition changes in NSPS Subparts Da, Db, and Dc as follows:

Natural gas means:
(1) A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or
(2) Liquid petroleum gas, as defined by the American Society of Testing and Materials in ASTM D1835 (incorporated by reference, see § 60.17); or
(3) A mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 34 and 43 megajoules (MJ) per dry standard cubic meter (910 and 1,150 Btu per dry standard cubic foot).

The addition of item 3 in the definition allows other gases that are essentially the same as natural gas, such as synthetic natural gas or treated landfill gas, to be included in the definition. It is unnecessary to restrict the definition to only gases from geologic formations. The net impact of this third definition is to promote the beneficial combustion of clean gaseous fuels, such as clean Landfill Gas, which might otherwise be released into the atmosphere or flared. As EPA has indicated in its Landfill Methane Outreach Program (LMOP),

The U.S. Environmental Protection Agency's Landfill Methane Outreach Program (LMOP) is a voluntary assistance program that helps to reduce methane emissions from landfills by encouraging the recovery and beneficial use of landfill gas (LFG) as an energy resource. LFG contains methane, a potent greenhouse gas that can be captured and used to fuel power plants, manufacturing facilities, vehicles, homes, and more.

http://www.epa.gov/lmop/

EPA should define "Natural Gas" to be identical to the definition in § 60.41Subpart Da. EPA could add a de minimus level of fuel dependent inorganic HAPs to this definition to ensure these HAPs are not present in gases qualifying as natural gas.

Comment Excerpt Number: 55

Comment: EPA defines "natural gas" in proposed § 63.7575, as:

(1) A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or
(2) Liquid petroleum gas, as defined by the American Society for Testing and Materials in ASTM D1835-03a, "Standard Specification for Liquid Petroleum Gases" (incorporated by reference, see § 63.14(b). [Footnote: 75 Fed. Reg. at 32,065.]

The first part of the definition seems to rely on EPA's definition of "natural gas" in several previous MACT standards promulgated by EPA. [Footnote: See Subpart HH, NESHAP from Oil and Natural Gas Production Facilities, 40 C.F.R. § 63.761; Subpart HHH, NESHAP from Natural Gas Transmission and Storage Facilities, 40 C.F.R. § 63.1271.] Both of these rules address processors and providers of natural gas, not customers or end users of the gas. Given that end users do not know or have control of the source of materials introduced into the distribution system, EPA's proposed definition of "natural gas" is problematic if any kind of biogas, landfill gas, or "synthetic gas converted from coal" is in the main pipe. EPA's proposed definition needs to be expanded to cover other types of fuel gases that are carried through the main pipeline.

To address this concern, the Auto Group recommends that EPA add a third component to the definition that would include "any gas that is transported through a commercial natural gas pipeline." This addition would allow fuel gases that are carried through the commercial pipeline to be treated as natural gas and regulated as such. Furthermore, it would not require consumers to determine what type of fuel gas is in the natural gas pipeline and whether that fuel gas comes from a geologic formation or from some other source that results in commercial grade natural gas.

Response: EPA has modified the definition of natural gas in the final rule to be consistent with the definition in 40 CFR part 60 subparts Db and Dc. These changes should address the concerns that sometimes natural gas utilities blend other fuels such as landfill gas or biogas into the pipeline and allow for sources other than geological formations that may enter the pipeline. It has also incorporated a definition of propane as part of natural gas. It has not included the commenters suggestion to include any gas that comes through a natural gas pipeline.

Comment: EPA also must clarify the definition in proposed § 63.7575 for "unit designed to burn oil subcategory." [Footnote: See 75 Fed. Reg. at 32,065.] As drafted, the definition states that gaseous fuel boilers and process heaters are not included in the oil-fired unit subcategory as long as the combined total hours of operation during gas curtailment, gas supply emergencies, or periodic testing of liquid fuel does not exceed 48 hours. [Footnote: See 75 Fed. Reg. at 32,065.] The Auto Group objects to the inclusion of periods of gas curtailment or supply emergencies given that end users have no control over the frequency or duration of these periods. Additionally, the proposed 48 hour limit does not provide adequate time to startup the oil burner, make adjustments and perform stack testing as may be required by state operating permits. This definition should be revised to eliminate the specified 48 hour limit.

Comment: The proposed definition in § 63.7575 for "waste heat process heater" also presents a concern that must be addressed by EPA in the final rule. According to the proposed definition, a "waste heat process heater" does not include those waste process heaters incorporating duct or supplemental burners designed to supply 50% or more of the total rated heat input capacity of the waste heat process heater. [Footnote: See 75 Fed. Reg. at 32,066.] The threshold for supplemental burners should be based on utilization instead of supplemental burner capacity. For example, supplemental burners are fired at high capacity during startup, but then "throttle back" to minimum level during normal operation. If the burner capacity is limited to less than 50%, then there would be startup problems for some sources.

Response: EPA has deleted the middle sentence of the definition, which included the 50 percent criteria, from the final rule.

Comment: The proposed definition of natural gas in §63.7575 includes only the prior NSPS definition, not the 2009 NSPS Subparts Db and Dc revisions. The natural gas definition for this rule needs to be consistent with that rule and should, therefore, also include the following: "(3) A mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 34 and 43 megajoules (MJ) per dry standard cubic meter (910 and 1,150 Btu per dry standard cubic foot)." The addition of item 3 in the definition allows other gases that are essentially the same as natural gas, such as synthetic natural gas or treated landfill gas, to be included in the definition. It is unnecessary to restrict the definition to only gases from geologic formations. The net impact of this third part of the definition is to promote the beneficial combustion of clean gaseous fuels, such as clean Landfill Gas, which might otherwise be released into the atmosphere or flared.

Comment Excerpt Number: 110

Comment: EPA has been very consistent throughout the proposal to use 10% as a threshold for movement from one subcategory to another. For example the most stringent – coal – includes units that burn at least 10% coal. The next – biomass – includes units that burn at least 10% biomass and less than 10% coal. The first sentence of the oil (liquid) subcategory includes any liquid fuel, but less than 10 % solid fuel. Therefore, it logically follows that a plain reading of the Gas 1 subcategory would be that EPA intended to include any unit that burns at least 90% gas and less than 10% of any other fuel. However, the second sentence in the oil (liquid) subcategory emphasized above is in contradiction with the Gas 1 definition by implying that any more than 48 hours (2 days) per year of liquid fuel firing would reclassify the unit into the liquid category. EPA should not limit liquid firing during periods of curtailment, and liquid firing during curtailment should not count toward any 10 percent liquid firing allowance, as these periods are out of the control of the boiler operator.

AF&PA proposes the following definition for the Gas 1 subcategory:

“The Gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas, propane, refinery gas, or off-gas streams for petrochemical and chemical plant processes on a heat input basis on an annual average and less than 10 percent of any solid or liquid fuel.”

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2729.1, Excerpt Number 6 to view the response.

Commenter Affiliation: Calgon Carbon Corp.
Document Control Number: EPA-HQ-OAR-2002-0058-2956.1
Comment Excerpt Number: 1

Comment: For purposes of regulatory clarity and consistency with other definitions in the proposed rule, the definition of "waste heat boiler" should be revised so that the delineation of heat input to a unit is based on an annual average. Several definitions in the proposed rule are based on the annual average heat input to a unit including "unit designed to bum gas 1 (NG/RG) subcategory" and "unit designed to bum coal." Accordingly, for consistency and clarity, we suggest the following changes to the definition of "waste heat boiler":

Waste heat boiler means a device that recovers normally unused energy and converts it to usable heat. Waste heat recovery boilers incorporating duct or supplemental burners that supply 50 percent or more of the total rated heat input eapaeity of the waste heat boiler, on an annual average, are not considered waste heat boilers, but are considered boilers. Waste heat boilers are also referred to as heat recovery steam generators.

Response: EPA has deleted the middle sentence of the definition, which included the 50 percent criteria, from the final rule.

Commenter Name: Walter Tyler
Commenter Affiliation: Invista
Document Control Number: EPA-HQ-OAR-2002-0058-2761.1
Comment Excerpt Number: 2

Comment: When comparing the above definition for the "oil" unit subcategory with the definition of the "Gas 1" subcategory, there is the potential for a conflict based on the 48-hour limitation in the "oil" subcategory definition. INVISTA, therefore, suggests that EPA clarify the oil subcategory definition by eliminating the phrase in the second sentence limiting a Gas 1 unit to 48 hours of oil burning. The revised "oil" subcategory text would be modified as follows:

Recommended Text in 63.7575, Definitions:
Unit designed to burn oil subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent solid fuel on a heat input basis on an annual capacity factor average, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year at less than a 90 percent annual capacity factor are not included in this definition.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2729.1, Excerpt Number 6 to view the response.

Commenter Name: James Santory

Document Control Number: EPA-HQ-OAR-2002-0058-2956.1
Comment Excerpt Number: 2

Comment: The EPA should clarify that the reference to duct or supplemental burners in the proposed definition of "waste heat boiler" means burners that introduce fuel directly into the combustion unit where the heat recovery is also located. Burners that introduce fuel in an upstream combustion unit (e.g., incinerator, thermal oxidizer, or afterburner) are part of the upstream combustion unit that is not a "boiler" because it has no heat recovery. Subsequent recovery of the waste heat in a downstream unit does not render the combustion unit a "boiler."

Response: EPA has updated the definition of waste-heat boiler within the final rule. Please refer to the response to comment EPA-HQ-OAR-2002-0058-2956.1, excerpt 1 or the final rule for updates to this definition.

Comment: This proposal applies to boilers and process heaters at major sources. Boiler is defined in proposed 63.7575 as an enclosed device using controlled flame combustion and having the primary purpose of recovering thermal energy in the form of steam or hot water. A device combusting solid waste, as defined in 40 CFR 241.3, is not a boiler. Waste heat boilers are excluded from this definition. However, the commercial/institutional boiler and industrial boiler definitions in 63.7575 include units that generate electricity, as well as those that generate steam or hot water. While there may not be any boilers that generate electricity without first

generating steam or hot water, there may be such devices in the future or these definitions might be misinterpreted to include devices that generate electricity without combustion, e.g., nuclear reactors, piezoelectric generators, wind turbines. Including electricity generation in the commercial/institutional boiler and industrial boiler definitions serves no purpose and should be removed, so that these definitions mirror the general boiler definition.
Recommendation: Remove electricity generation from the definitions of commercial/institutional boiler and industrial boiler in 63.7575.

Response: EPA has removed "electricity generation" from the definitions in the final rule as per commenter's request. This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2960.1, Excerpt Number 3 to view the response.

Comment: Waste heat boilers are appropriately excluded from the definition of boiler. However, waste heat boiler is defined in 63.7575 not to include waste heat boilers that have supplemental firing, where ?50% of the heat duty of the waste heat boiler comes from supplemental firing. It is unreasonable to consider such supplementary fired waste heat systems as boilers for the purposes of this rule, because their characteristics were not considered in the rulemaking record, they are not represented in the database, the rule compliance procedures are inappropriate for such equipment, the controls considered for normal boilers and process heaters are not applicable and the interactions with other NESHAP rules have not been addressed.

The data record for this proposal did not address these situations or demonstrate what MACT would be for supplementary fired boilers. Because the configuration of a supplementary fired system is totally different than that of a traditional boiler, results from a traditional boiler cannot be extended to supplementary fired boilers. Nor would we expect similar combustion characteristics, since the flame occurs in a different atmosphere and under different temperature, pressure and composition conditions than those in a traditional boiler. For instance, the O2 content of the flame zone for a supplementary fired burner is dependent on the O2 content of the exhaust gas from the primary combustion device and is typically well below the O2 content of air. This characteristic alone, significantly impacts the stack organic HAP, CO and NOx emissions.

A good example of the problem is a waste heat system in a sulfur recovery unit incinerator stack. Because the gases in an SRU incinerator have low heating value, it is very easy for the 50% criteria in the proposal to be exceeded. Clearly, there is nothing in the EPA database that approximates this situation and none of the analyses addressed this type of mixed stack gas. It is not even clear whether the types of controls EPA has considered would work in this unusual environment.

Combustion emissions from supplementary fired waste heat systems are exhausted from the stack of the combustion device (often a gas turbine) from which the waste heat is being recovered. Thus, the emissions from the two devices are combined. The stack monitoring and testing procedures specified in the proposal would not work, because the emissions from the supplementary fired system cannot be distinguished from the emissions of the other combustion source.

Furthermore, add-on controls for supplementary fired equipment would be much different than for normal boilers or process heaters, because they would be handling gas from two combustion sources, the exhaust system is constructed differently, the exhaust gas has different properties and, particularly for gas turbines, the backpressure exerted by add-on controls increases fuel use and emissions from the primary combustion device as well as the waste heat system and could interfere with the add-on NOx controls that are already in place for many such systems. For all of these reasons, the controls evaluated in this rulemaking are not appropriate for or reflective of the controls that would be used for supplementary waste heat systems.

Finally, the primary combustion source is usually already subject to a set of requirements (e.g., NSPS GG and KKKK and/or NESHAP rules such as Part 63 Subpart YYYY and/or SIP requirements) and the Agency has not considered how this proposal would interact with those existing requirements.

Overall, we do not believe the Agency has shown that any supplementary fired boilers have been considered in any portion of this rulemaking or that this NESHAP proposal was developed with such units considered. Thus, there is no technical or legal basis for applying the proposed standards to supplementary fired boilers of any firing percentage.

Recommendation: Revise the definition of waste heat boiler to eliminate the 50% criteria. We recommend the following:

Waste Heat Boiler means a device that recovers normally unused energy and converts it to usable heat. Waste heat recovery boilers incorporating duct or supplemental burners are considered waste heat boilers

If the 50% criterion is not removed, the Agency must clarify it. Under the proposed definition of waste heat boiler in 63.7575 duct or supplemental burners that are designed to supply 50 percent or more of the total rated heat input capacity of the waste heat boiler are not considered waste heat boilers. However, heat input is defined in the same section as "Heat input means heat derived from combustion of fuel in a boiler or process heater and does

not include the heat input from preheated combustion air, recirculated flue gases, or exhaust gases from other sources such as gas turbines, internal combustion engines, kilns, etc." Based on the heat input definition all supplemental firing is 100%, because you can only count the fuel fired in establishing the total rated heat input capacity of the waste heat system.

Recommendation: If the 50% criterion is maintained, establish the 50% as the annual firing of the supplemental burner(s) divided by the total rated waste heat recovery.

Response: EPA has updated the definition of waste-heat boiler within the final rule. Please refer to the response to comment EPA-HQ-OAR-2002-0058-2956.1, excerpt 1 or the final rule for updates to this definition.

Comment: Natural gas is defined in the proposal as follows.

Natural gas means:
(1) A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or
(2) Liquid petroleum gas, as defined by the American Society for Testing and Materials in ASTM D183503a, ?'standard Specification for Liquid Petroleum Gases" (incorporated by reference, see 63.14(b)).

The latest definition of natural gas in the NSPS Subpart Db and Dc rules also include a paragraph 3 as follows in order to include synthetic natural gas generated from coal3. [Footnote: Added to the NSPS subparts by amendment on January 28, 2009 (74 FR 5072).]

a mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 34 and 43 megajoules (MJ) per dry standard cubic meter (910 and 1,150 Btu per dry standard cubic foot)

This paragraph should be added to the proposed definition, so this rule is consistent with the other combustion rules potentially applicable to these units.

Recommendation: Add paragraph 3 from the NSPS Subparts Db and Dc natural gas definitions to the natural gas definition in this rule.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2775.1, Excerpt Number 55 to view the response.

Comment: Process heater is defined in 63.7575 as “an enclosed device using controlled flame, that is not a boiler, and the unit’s primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam. Process heaters are devices in which the combustion gases do not directly come into contact with process materials....”
We are unclear what the phrase that is not a boiler means and suggest it be deleted. Per the boiler definition, a boiler has the primary purpose of producing steam or hot water, while, according to the process heater definition, a process heater has the primary purpose of providing heat to a process material or a heat transfer material. Since a unit cannot have two primary purposes, a process heater cannot be a boiler as the quoted phrase would seem to suggest. Thus, we recommend the phase be deleted from the process heater definition. We note that it is not uncommon for some process heaters to generate significant quantities of steam from waste heat. Thus, the suggestion that a unit can only be a process heater if it is not a boiler (i.e., a steam generator) significantly confuses the determination of device type.
Recommendation: Remove the term “that is not a boiler” from the process heater definition.

Response: EPA acknowledges the comment and removed "that is not a boiler" from the definition of process heater in the final rule.

Comment: The definition of units designed to burn Gas 1 and units designed to burn Gas 2 must be clarified (40 CFR 63.7575, 75 FR 32017). The definitions of units to define Gas 1 and Gas 2 in 40 CFR 63.7575 are ambiguous in the proposed rule. A Gas 1 unit burns at least 90 percent Gas 1 (without specifying any restriction on the remaining 10 percent). A Gas 2 unit burns "gaseous fuels other than ... (Gas 1) ... not combined with any other solid or liquid fuels." The firing of Gas 2 versus Gas 1 is not specified. The definitions do not affirmatively resolve the status of a unit that burns, for example, 91 percent Gas 1 and 9 percent Gas 2. It would seem logical that such a unit would be considered Gas 1, and discussion in the Boiler MACT preamble seem to support that interpretation (75 FR 32017). However, this interpretation should be clarified in the definitions that will be included in the regulation as an alternative assumption could have a dramatic effect on unit requirements.

Response: In response to a similar comment, this issue has been resolved by amending the definition of Gas 2 unit to eliminate the ambiguity.

Comment: It also is unreasonable for EPA to classify as a deviation "any period for which the monitoring system is out of control and data are not available for required calculations." Proposed 63.7525(a)(6). There will be times, even with a well-maintained and functioning CEMS, where the system will be out of operation. No technology is infallible. Many state permits recognize this reality and require data availability for a minimum percentage of operating hours in month or quarter with the minimum percentage depending on the CEMS technology. EPA should amend Proposed 63.7525(a)(6) to allow for some reasonable amounts of missing data.

Response: EPA acknowledges the comment but the definition of deviation in 63.7525(a)(6) has remained as proposed.

Comment: The last sentence of the temporary boiler definition specifies that Any temporary boiler that replaces a temporary boiler at a location and is intended to perform the same or similar function will be included in calculating the consecutive time period. This language creates a problem because there is no time period associated with the replacement. It is not unusual for a temporary boiler to be used for less than 180 days during turnarounds that occur several years apart. Under the proposal these boilers would not be considered temporary, because each boiler replaces the previous one and performs the same function, even though there is a significant gap between the occurrences. We believe that replacements that occur after a gap of at least one year should not be considered consecutive for the purposes of this definition.

Recommendation: Revise the last sentence of the proposed temporary boiler definition, as follows:

Any temporary boiler that replaces a temporary boiler at a location and is intended to perform the same or similar function will be included in calculating the consecutive time period, if the replacement occurs within 12 months of the removal of the previous temporary boiler.

Response: EPA acknowledges the comment and revised the definition to match the definition of "portable" in the GHG reporting rule, as suggested by another commenter.

Comment: The proposed Gas 2 subcategory definition would capture units that also meet the Gas 1 definition, because they burn <10% Gas 2. Similarly, the Gas 2 definition would not allow a unit that fires primarily Gas 2 to fire up to 10% liquids, as the Gas 1 and liquid subcategory definitions allow and as the preamble states is the intent [Footnote: On page 32012 it states If your new or existing boiler or process heater burns gaseous fuel and less than 10 percent, on an annual average heat input basis, of liquid or solid fuel, we are proposing that the unit is in one of the gas subcategories]. In these situations, it appears a particular unit could be in more than one subcategory at the same time. We, therefore, recommend that the gas subcategory definitions be revised as follows, including the revisions recommended in comment II.C.a.1 if two gas subcategories are maintained in the final rule.
Unit designed to that burns gas 1 (NG/RG) subcategory includes any boiler or process heater that burneds at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual averagein the previous calendar year.

Unit designed to that burns gas 2 (other) subcategory includes any boiler or process heater that burneds greater than 10 percent gaseous fuels other than natural gas and/or refinery gas and less than 10% not combined with any solid or liquid fuels on a heat input basis in the previous calendar year.

Recommendation: Make the Gas 1 and Gas 2 subcategory definitions consistent as recommended above.

Response: EPA has revised the definitions of units designed to burn gas 1 and units designed to burn gas 2 to avoid overlap of the subcategories in the final rule. See final rule for revised definitions.

Comment: Proposed section 63.7575 contains two different definitions for the subcategory covering liquid fuels.

The proposed definition of “liquid fuel subcategory” should be removed and any use of the term “liquid fuel subcategory” anywhere in the regulatory language should be replaced.

The term “unit designed to burn liquid fuel,” should be used exclusively and consistently throughout the rule and in the Tables. “Liquid” is a clearer and more comprehensive term than “oil” and we therefore believe that term should be used throughout the rule. Using consistent terminology throughout the regulation is critical to assuring understanding of the requirements.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2863.1, Excerpt Number 54 to view the response.

Comment: Under the proposed definitions, units that burn gas and <10% liquid on an annual basis would appear to be in both a "gas subcategory" and the "unit designed to burn oil subcategory." This needs to be corrected. Furthermore, the proposed exclusion for gas-fired units that burn oil during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel from the liquid subcategory would appear to be unworkable as drafted because it appears to only allow oil firing for 48 hours a year. As experience has repeatedly shown, natural gas curtailments due to hurricanes in the Gulf of Mexico will almost always exceed 48 hours. We assume the 48 hours was meant to apply only to the testing situation, and the draft language does not accurately represent the Agency intent. To address these two issues and the changes suggested in comment II.C.1, we recommend the following. These changes would also make this definition consistent with the gas subcategory definitions as suggested in Comment II.C.b.1.

Unit designed to that burns oil liquid subcategory includes any boiler or process heater that burnsed anymore than 10 percent liquid fuel, but less than 10 percent solid fuel on a heat input basis in the previous calendar yearon an annual average, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or, gas supply emergencies are not included in this definition. Gaseous fuel boilers and process heaters that burn liquid fuel or for periodic testing, of liquid fuel not to exceed a combined total of 48 hours during any calendar year, are not included in this definition.

Comment: We recommend that the definition of wet scrubber be modified to include that there is an aqueous byproduct to be consistent with the operating limits imposed on this type of control device and with the definition of dry scrubber that references formation of a dry powder material. Our coal boilers are each equipped with a spray dry absorber (SDA) which injects a lime slurry with a dry power formed and collected in a baghouse. Our SDAs meet the definition of both a dry scrubber and wet scrubber as currently written, but the operating parameters for a wet scrubber do not apply.

Response: EPA has added a sentence in the final rule to read: “A wet scrubber creates an aqueous stream or slurry as a byproduct of the emissions control process.”

Comment: C. EPA’s Proposed Definition of Gas 2 Units is Flawed.

EPA’s proposed definition for Gas 2 units does not include de minimus threshold. Therefore, under the Proposed Rule any use of gas other than natural gas or refinery gas will result in the imposition of emissions limits instead of work practices for the gas fired unit. Such a result is unreasonable and will result in the decreased use of off-gas and landfill gas. EPA has recently promoted the use of these alternative gases; therefore, such a result is clearly not in keeping with the agency’s overall goals and policy.

Comment: FSI has several comments on the definitions:

Bagasse boiler – see the FSI’s comments submitted to the docket on July 23, 2010.

Biomass fuel – consistent with comments submitted by FSI on the proposed rule regarding the Definition of Solid Waste, this definition should explicitly state that these materials are not solid wastes when burned as fuel in boilers or process heaters for energy recovery.

Boiler system – the “energy consuming systems” could be interpreted to reach well beyond the traditional boundaries of the boiler, since everything in a facility that uses steam could be considered as part of the boiler. This is beyond the authority of §112, which limits the scope of the rule to the "affected source".

Fuel type – in keeping with the request for a separate subcategory for bagasse boilers, it is requested that bagasse be listed as a specific fuel type. Just as there are different types of coal listed as specific fuel types (bituminous, subbituminous), so there are different types of biomass which are combusted differently in specially designed boilers. One of these biomass types is bagasse.

Unit designed to burn biomass subcategory – consistent with our previous comments, this definition should be revised to include all units which burn more than 10 percent biomass on an annual average heat input basis.

Unit designed to burn bagasse subcategory – consistent with our previous comments, this definition should be added to identify a separate subcategory for those units which burn more than 10 percent bagasse on an annual average heat input basis.

Temporary boiler – consistent with other related rules and the Clean Air Act (i.e., non-road engines), this definition should be revised to allow a boiler to remain at a location for up to 12 months and still be classified as a temporary boiler.

Response: EPA acknowledges the comment but did not update the definition of temporary boiler and any boiler that remains at a location for more than 180 consecutive days is no longer considered to be a temporary boiler.

The fuel type comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2765.1, Excerpt Number 35 to view the response.

The temporary boiler comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2960.1, Excerpt Number 21 to view the response.

Comment: Tune-up is defined in proposed 63.7575 as Tune-up means adjustments made to a boiler in accordance with procedures supplied by the manufacturer (or an approved specialist) to optimize the combustion efficiency. However, 63.7540(a)(10) specifies what the work practice "tune-up" must include and that does not match the proposed definition. The proposed definition should be deleted.

Recommendation: Delete the proposed definition of “tune-up”.

Response: EPA has removed the definition from the final rule because it is covered in the rule language.

Comment: Liquid Fired Units
A. Definition of Units Designed to Burn Oil Should Be Amended.
The proposed definition of the subcategory of "units designed to burn oil." needs to be clarified. In the Proposed Rule, EPA defines the subcategory of "units designed to burn oil." as follows:

Unit designed to burn oil subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent solid fuel on a heat input basis on an annual average, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year are not included in this definition. 75 FR 32065.

The proposed definition is unreasonable because, as it is currently phrased, gaseous fuel boilers and process heaters could be limited to only 48 combined total hours during a calendar year before they are included in this subcategory. EPA should clarify the "units designed to burn oil" subcategory to apply only to the time the unit is operated on oil for periodic testing of oil firing capability. EPA should impose no time limit on legitimate gas curtailment or gas supply emergencies. Such a change would be reasonable and better reflect EPA’s intent for units that burn liquid as evidenced by the "gas-fired boiler" definition in the Proposed Area Source Rule. 75 FR 31931.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2729.1, Excerpt Number 6 to view the response.

Comment Excerpt Number: 91

Comment: In the Proposed Area Source Rule, EPA defines gas-fired boiler as "any boiler that burns gaseous fuels not combined with any solid fuels, burns liquid fuel only during periods of gas curtailment, gas supply emergencies, or periodic testing on liquid fuel. Periodic testing of liquid fuel shall not exceed a combined total of 48 hours during any calendar year." 75 FR 31931. Notably, EPA imposes the 48 hour limitation only on the "[p]eriodic testing of liquid fuel" and there is no limit on legitimate gas curtailment or gas supply emergencies. Beyond consistency with the Proposed Area Source Rule, this rectification of the definition would be similar to EPA’s approach in the stationary SI internal combustion engine ("ICE") NSPS, where 50 hours are allowed for non-emergency use. See 40 C.F.R. 60.4243.

Comment: B. CIBO Recommends that EPA Expand the Definition of Gaseous Fuel Fired Boilers and Process Heaters to Include Periods of Gas Curtailment when Backup Liquid Fuel Must be Fired.
Federal, state, or local governments and gas suppliers have in the past required a facility to curtail its use of natural gas so that it can be used for home heating or another critical need. The length of the curtailment usually lasts a very short time period during which the facility may either restrict production or switch to a liquid fuel to maintain the same level of production. These occurrences will only be taken in the national interest or for regional or local emergency type situations and only for a short time period. Onsite gas supply emergencies could also occur whereby use of gas fuel is not possible and backup liquid fuel firing is required in order to maintain critical production or services. Periods of backup fuel use would be limited to the time to complete repairs and safely return the gaseous fuel system to service.

CIBO requests that EPA expand the definition of gaseous fuel-fired boilers and process heaters to include gas curtailment required by a government agency (federal, state, local), natural gas supplier, or on-site gaseous fuel system emergencies. During the limited time of curtailment when the facility switches from gas to backup liquid fuel (recommended to be limited to 876 hours per year (10%)), new or reconstructed boiler and process heater affected sources would be exempt from complying with the liquid fuel standards (if they are included in the final rule). The exemption should allow for periodic backup fuel operation and testing in order to prove that it is available and reliable should it be needed; that testing time should be included within the 876-hour limit. In addition, this 10% annual time allowance would also allow for periodic operation on oil to allow turnover of oil in the storage tank to prevent oil degradation that might impact reliability when needed in an emergency. A facility should be able to apply to the permitting authority for an extension of the 876-hour exclusion if curtailments cause the unit to exceed that time limit.

Documentation of time firing backup fuel should be provided to the permitting authority by the affected source as part of the semi-annual reporting requirement. A review of California rules (i.e., Ventura County Rule 74.15; Kern Rule 435.2; Bay Area Rule 9.7; Santa Barbara Count Rule 342; Yolo-Solana Rule 2.27; South Coast Rule 1146; and SCAWMD Rule 1109) shows substantial relaxation of requirements in recognition of natural gas curtailments. Each of the California rules provides for less stringent limits when a normally gas-fired unit burns liquids - during a curtailment and while testing to assure operability on liquids in case a curtailment should occur.

If there is a curtailment of natural gas because of National interest, it is important as part of our National Energy Policy that refineries and petrochemical plants be allowed to continue production at the pre- curtailment levels so that there is a sufficient supply of home heating oil, jet fuel, diesel, gasoline, feedstocks, etc. If facilities are forced to limit production, the reduction in supplies may further intensify the problem because of the reduction in supply of products such as home heating oil, diesel, jet fuel, and gasoline. Similar issues exist at other critical manufacturing facilities.

The exemption would enable the facility to operate under the pre- curtailment gaseous fuel compliance requirements and thus be excluded from the liquid fuel requirements. Further, new or reconstructed units would not be required to install pollution control equipment required for liquid fuels which may never be used or only used for a very short time period over many years.

Comment: Table 6 provides for use of equivalent methods to those specified in the Table. Equivalent
methods is a defined term and the definition in 63.7575 is so restrictive as to be of little or no value. The definition should be revised to allow use of any analytical method that is shown to be equivalent to the cited EPA method using Part 63 Appendix A Method 301 or any method approved as equivalent by the appropriate permitting authority. Having EPA review and approve hundreds or thousands of such requests is a waste of EPA's and the sources time.

Recommendation: Revise the definition of “equivalent method” to include methods demonstrated by the source to be equivalent using Method 301 of Part 63 Appendix A.

Response: EPA acknowledges the comment but has retained the "or equivalent" terminology consistent with the proposed version.

Comment: Definition of Natural Gas.
EPA failed to use the definition of "Natural Gas" that represents the most current thinking of the agency. The definition adopted in § 60.41 Subpart Da, published in the Federal Register on 28th January 2009 (Federal Register /Vol. 74, No. 17 /Wednesday, January 28, 2009 /Rules and Regulations, p. 5079) includes an third definition of Natural Gas to read,

§ 60.41Da Definitions. Natural gas means:

(1) A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or

(2) Liquid petroleum gas, as defined by the American Society of Testing and Materials in ASTM D1835 (incorporated by reference, see § 60.17); or

(3) A mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 34 and 43 megajoules (MJ) per dry standard cubic meter (910 and 1,150 Btu per dry standard cubic foot).

This third definition enables affected sources to burn gaseous fuels that are substantially similar to naturally occurring natural gas without being subject to a variety of additional requirements that impose a regulatory and cost burden on the source. The net impact of this third definition is to promote the beneficial combustion of clean gaseous fuels, such as clean Landfill Gas, which might otherwise be released into the atmosphere or flared. As EPA has indicated in its Landfill Methane Outreach Program (LMOP), The U.S. Environmental Protection Agency's Landfill Methane Outreach Program (LMOP) is a voluntary assistance program that helps to reduce methane emissions from landfills by encouraging the recovery and beneficial use of landfill gas (LFG) as an energy resource. LFG contains methane, a potent greenhouse gas that can be captured and used to fuel power plants, manufacturing facilities, vehicles, homes, and more.

http://www.epa.gov/lmop/

By failing to adopt the most current definition of "Natural Gas", as incorporated into § 60.41 Subpart Da, EPA is inhibiting sources from burning clean gaseous fuels like Landfill Gas that could be beneficially combusted. EPA should define "Natural Gas" to be identical to the definition in § 60.41Subpart Da.

Comment: Some devices use electricity to heat water or produce steam. These are not generally thought of as enclosed combustion devices, but enclosed combustion is not a defined term and could be reinterpreted in the future.

Recommendation: Clarify that devices that use electricity to heat water or produce steam are not "boilers" under this proposal.

Response: See repsonse to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 2 for updates made to the definition of boiler within the final rule.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 8

Comment: Natural gas, as described in paragraph 1 of the proposed definition, must be separated from oil, production water, and solids and adjusted to pipeline specifications in production batteries and in natural gas plants. Thus, natural gas is generally processed to some degree prior to using as a fuel and thus might be construed as not being a naturally occurring mixture. Additionally, intermediate gas streams (i.e., gas streams that are separated from the hydrocarbon/water mixture removed from the ground that do not yet meet the pipeline quality natural gas specifications) are combusted in boilers and process heaters at the production site or the gas plant. Thus, we believe some clarification is needed in the definition of natural gas to be clear that processed and intermediate streams are included.

Recommendation: Clarify that gases derived from the "naturally occurring mixture found in geological formations" meets the definition of natural gas, as long as the principal constituent is methane, by revising proposed paragraph 1 as follows.

(1) A naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane, including intermediate gas streams generated during processing of natural gas at production sites or at gas processing plants; or

Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 35

Comment: In 63.7575, the second sentence in the definition for "Coal" is incomplete. It states "Synthetic fuels derived from coal for the purposes of creating useful heat including, but not limited to, solvent-refined coal, coal-oil mixtures, and coal water mixtures, for the purposes of this subpart." It is not clear whether this sentence intends to include or exclude these materials from the definition of coal. This definition should be clarified.

Response: See preamble for discussion of new solid fuel subcategory. EPA has revised the second sentence of the definition to include synthetic fuels in the final rule.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 36

Comment: Duke Energy agrees with and supports the definition given in §63.7575 for “fuel type”. Specifically Duke Energy agrees that receiving fuel from different suppliers does not constitute and change in fuel type.

Response: The EPA thanks the commenter for their support of the definition for "fuel type."

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-2765.1
Comment Excerpt Number: 37

Comment: Duke Energy believes that EPA’s definition of a hot water heater is overly restrictive, or at best confusing. In §63.7575, EPA defines a Hot water heater as “a closed vessel with a capacity of no more than 120 U.S. gallons in whish water is heated by combustion of gaseous or liquid fuel... at pressures not exceeding 160 psig...” By this definition, regulated sources could include a very large number of hot water heaters used by offices, hospitals, schools, commercial businesses, and other non-industrial sources. Water could be used for bathing, dish washing, space heating and other similar purposes not associated with industrial

activities. While these types of hot water heaters are typically found at sources that are not considered major sources of HAPs, major source facilities sources can also have these types of hot water heaters. EPA should restrict the definition of a hot water heater for purposes of this rule to include only units that are specifically used as part of an industrial process. EPA should consider increasing the capacity of these units above 120 gallons.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2998.1, Excerpt Number 46 to view the response.

Document Control Number: EPA-HQ-OAR-2002-0058-2632.1
Comment Excerpt Number: 86

Comment: The Term “total rated heat input capacity” in the Definition for Waste Heat Boiler is Ambiguous and not used in Industry so it Should Be Clarified. The definition of "Waste heat boiler", copied below, refers to the “total rated heat input capacity” of the waste heat boiler.

There are essentially two sources of heat to a Waste Heat Boiler: waste heat from an energy source (e.g., gas turbine or internal combustion engine), and heat release from duct or supplemental burners. The waste heat from the energy source can vary with ambient temperature, atmospheric pressure and humidity. That variation affects the exhaust gas flow and temperature from the energy source. Changing flow and temperature result in different heat releases from the equipment. The Waste Heat Boiler manufacturer designs their equipment for the expected range of flows and temperatures, but does not specify a rated heat input value. Therefore, the phrase “total rated heat input capacity” is ambiguous because it is not established by the Waste Heat Boiler manufacturer. However, manufacturers of the energy source do establish accepted reference conditions.

The manufacturer of the energy source, such as a gas turbine manufacturer, recognizes that changing ambient conditions affects power output, waste heat flow and waste heat temperature. Therefore, the gas turbine industry establishes a specific reference for ambient conditions called ISO conditions (59°F, sea level, 60% relative humidity). The EPA use of the term “heat input” in the definition of Waste Heat Boiler should be based on reference conditions associated with the energy supplier to avoid ambiguity.

The heat release from the duct or supplemental burners is provided by the burner manufacturer. No additional clarification is required on heat input from the burners.

Dow suggests the following addition to the definition of Waste Heat Boiler:
Waste heat boiler means a device that recovers normally unused energy and converts it to usable heat. Waste heat recovery boilers incorporating duct or supplemental burners that are designed to supply 50 percent or more of the total rated heat input capacity of the waste heat boiler are not considered waste heat boilers, but are considered boilers. Waste heat boilers are also referred to as heat recovery steam generators. Use industry established reference conditions associated with the energy supplier for determining their rated heat release, such as ISO ratings for gas turbines.

Response: EPA has modifed the definition of waste heat boiler in the final rule so that it includes all waste heat boilers instead of considering only those units with 50 percent or more of their waste heat. Please refer to the response to comment EPA-HQ-OAR-2002-0058-2956.1, excerpt 1 or the final rule for updates to this definition.

Comment: EPA Should Modify the Definition of Tune-up to Reflect that it is a Process and Not a Procedure.

Boiler tune-up is a process, not a procedure. The combustion specialist knows how to adjust hardware or combustion control elements in order to improve combustion efficiency and maintain safety. That knowledge is based on training and experience consistent throughout the industry. There are too many variables involved in the adjustments that it would be near impossible to have written procedures to cover all possible tune-up adjustments. The specialist evaluates the 'as found' condition of the equipment, then applies his/her knowledge of appropriate adjustments to improve its performance.

The section on demonstrating continuous compliance recognizes that tuning is a process. Section 63.7540(a)(10)(i - vi) lists the elements to be covered during the tune-up process (e.g., burner inspection, flame pattern, air to fuel ratio, etc.).

Thus, the definition of tune-up should eliminate references to procedures, and Dow recommends the following revised definition:

Tune-up means adjustments made to a boiler, in accordance with industry combustion practices, that are performed procedures supplied by the manufacturer's representative or an approved specialist to optimize the combustion efficiency.

Comment: There are two definitions for the liquid fuel burning units, it is unclear as to which one is correct re: "Liquid fuel subcategory" on Page 32064, and "Units designed to burn oil subcategory". Table 1 refers to this subcategory as "Units designed to burn liquid fuel". This seems erroneous as the subcategory shall be determined on an annual heat input basis, not design basis, as described in the definition. Consumers seeks further definition and clarity in this area.

Consumers has found that the emission limit proposed for carbon monoxide ("CO") for oil fired boilers is not achievable. Consumers has a permit to install a 65 mmBTU/hr distillate oil fired boiler. Consumers Energy has solicited five (5) well established U.S. manufacturers of package boilers to bid the package boiler and all were unanimous in not being able to meet the proposed regulation. Burners are typically designed for <50 PPM CO and <I OOPPM CO depending upon the application. There is no burner manufacturer that will design a burner to 1 PPM CO, as this will never be a feasible or cost effective goal in burner engineering. As a result of this proposed rule, Consumers has placed this installation project on hold and we are unable to proceed with installation of a much needed unit.

Comment: Definitions — section 63.7575 [Period of natural pas curtailment or supply interruption]

Period of natural gas curtailment or supply interruption is defined as "a period of time during which the supply of natural gas to an affected facility is halted for reasons beyond the control of the facility. An increase in the cost or unit price of natural gas does not constitute a period of natural gas curtailment or supply interruption."
Many U.S. manufacturing facilities that utilize natural gas-fired boilers and process heaters, which also have the capability to burn alternative fuels, operate under contractual supply agreements with local utilities. The utilities offer these customers a reduced cost in natural gas in exchange for the ability to curtail the supply when the regional demand is high, typically during winter months, which in turn helps to prevent supply shortages to its other customers. During the contract period, natural gas supply may be curtailed at any time, which is in fact beyond the control of the facility. However, the establishment of the contract itself is technically not beyond the control of the facility.

1. PFI requests guidance and clarification on what is considered to be "reasons beyond the control of the facility" — This definition was added to the final vacated rule (69 FR 55218), presumably due to comments received based on the proposed rule (68 FR 1660) since it was not included in that document. However, PFI was unable to locate any information in the preamble to the final vacated rule or in this proposed rule related to the intent of the definition's meaning (i.e., no discussion on what is meant by "reasons beyond the control of the facility").

PFI assumes that is not the intent of the definition to include contractual arrangements with a supplier of natural gas as a reason that is in control of the facility, since virtually no facility that is subject to curtailment would meet the terms of this definition. However, PFI believes the intent should be clarified to help avoid ambiguity and misinterpretations, either by modification of the definition or in the form of a discussion in the preamble to the final rule, at a minimum. The following is a suggested modification to the definition based on the comments referenced in this section:

"Period of natural gas curtailment or supply interruption means a period of time during which the supply of natural gas to an affected facility is halted for reasons beyond the control of the facility. The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. An increase in the cost or unit price of natural gas does not constitute a period of natural gas curtailment or supply interruption."

Response: EPA has revised the definition in the final rule to match commenter's suggestion.

Comment: Definition of "Heat Input" Should Include Heat Captured from the Combustion of Process Off Gases

Process equipment with a direct fired fuel source to melt or otherwise convert raw materials into intermediate or finished products may generate off gases that are suitable to combust for heat recovery in either waste heat boilers or waste heat process heaters. The off gases from these processes contain both the products of combustion and reaction products from the raw materials and fuels utilized. These types of furnaces were not considered in the information collection request for development of the proposed Boiler MACT standard.

The types of waste heat boilers and process heaters surveyed as part of the information collection request for the Boiler MACT were either boilers firing fossil fuels or firing combustible by-products generated by the process. EPA considered the use of off gases to fire a boiler or process heater and exempted it from regulation, provided that the design of the boiler or process heater allowed no more than 50 percent of the heat energy could be obtained from the firing of supplemental fuels.

As a result, at least 50 percent of the heat input must come from combustion of process off gases. Nonetheless, EPA failed to include process off gas in the definition of fuels or in the definition of heat input.

The Boiler MACT data base from the boiler and process heater survey does not contain any process heaters that are fueled by by-product or off gas streams, but it does contain waste heat boiler applications for a variety of process types. It is good engineering practice to utilize process waste gas streams wherever practicable, especially when the gas streams have high heat value. Typically, the most effective uses of these waste gas streams are for heat recovery systems that are self contained within the process.

The definition for “heat input,” should include the heat captured from the combustion of the process off gases. Without this addition, there is no way to verify that the waste heat process heater is not an affected source regulated by Boiler MACT. Accordingly, EPA should amend the definition of “heat input” in 40 CFR § 63.7575 to include the following underlined text:

Heat input means heat derived from combustion of fuel or process off gas in a boiler or process heater system and does not include the sensible heat from preheated combustion air, re-circulated flue gases, or exhaust gases from other sources such as gas turbines, internal combustion engines, kilns, etc.

This clarification will clearly identify that the heat input used for determining the applicability of the waste heat boiler and waste heat process heater definitions can be calculated and clearly demonstrated. A definition that distinguishes sensible heat from the heat input in these systems is necessary for the determination of applicability as a waste heat unit.

Response: EPA has removed the following provision from the proposed definition of waste heat boiler "Waste heat recovery boilers incorporating duct or supplemental burners that are designed to supply 50 percent or more of the total rated heat input capacity of the waste heat boiler are not considered waste heat boilers, but are considered boilers." The final definition was revised to include all waste heat boilers. These changes were made to exempt the units it intended at proposal.

Comment: The definitions for “boiler” in the proposed major source rule and area source rule are different. For consistency, EPA needs to clarify the two definitions.

Response: See response to comment EPA-HQ-OAR-2002-0058-2960.1, excerpt 2 for updates made to the definition of boiler within the final rule.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 3

Comment: One of the difficulties that the Division has encountered is the use of boilers/process heaters to provide heat to various processes at a source (dryers, steam press, etc.) using thermal oil. The source argued that when the boilers/process heaters stopped using thermal oil to transfer heat, and instead sent the combustion air to the dryers, the units were no longer boilers/process heaters but direct fired units. The boilers/process heaters were enclosed combustion devices used to recover thermal energy by sending the heat of combustion from one location at the facility to various other locations at the facility. Like steam, hot combustion air is a legitimate heat transfer medium. The only difference is that energy was delivered to other processes using a gas (air) instead of a liquid (thermal oil). The heat transfer medium should not matter. It is preferable that the term "heat transfer medium" be used (as it is defined in 40 CFR 60 Subpart D) to prevent this confusion. It is not the intention of the Division to incorporate direct-fired units into these regulations. But stand-alone combustion units with a controlled flame that are not directly tied to process equipment should be regulated as boilers/process heaters. The regulation needs to clarify the classification of units under these conditions.

Comment: Definitions — section 63.7575 [Process heaterl
Process heater is defined as "an enclosed device using controlled flame, that is not a boiler, and the unit's primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam. Process heaters are devices in which the combustion gases do not directly come into contact with process materials. A device combusting solid waste, as defined in 40 CFR 241.3, is not a process heater. Process heaters do not include units used for comfort heat or space heat, food preparation for on-site consumption, or autoclaves."

PFI requests guidance and clarification on whether a batch-type pyrolysis oven/furnace that is used to remove (burn-off) hardened polymer from metal process parts (e.g., spinnerets, etc.) would meet the intent of this definition and thus be subject to this subpart. Typically, these types of ovens have a maximum rated heat input capacity of 0.5 MM BTU/hr or less.

Response: If the unit combusts solid waste, such as units that use high temperature to break the bond between the paint and the metal and then combust the paint flakes, leaving only ash, it is considered to combust solid waste, unless it qualifies as a metals recovery unit, and therefore not subject to the boiler and process heater standards. If it does not combust solid waste, such as units that only crack the bond at low temperatures where the paint flakes off of the metal and is collected, and thrown away, it would be subject to boiler MACT only if it is located at a major source. Since all of the units are small, it would be subject only to work practice standards under this standard.

Comment: The definition of gas-fired boilers includes those units burning gaseous fuels, which by further definition includes process gases (e.g., coke oven gas, blast furnace gas, or basic furnace off-gas). However, the definition of gas-fired boiler is qualified by stating that gaseous fuels cannot be combined with any liquid fuel except during periods of gas curtailment, gas supply emergencies, or periodic testing on liquid fuels. Without clarification of that definition, the exemption for gas fired boilers is potentially negated.

While coke oven gas boilers are primarily designed to burn coke oven gas, usually with natural gas as a back-up fuel, they are sometimes supplemented with liquid fuels when the supply of coke oven gas from the coke oven process is interrupted due to operational difficulties or reduced operations necessitated by business conditions or when steam demands elsewhere in the plant that rely on steam from those boilers cannot be met by the available coke oven gas supply to the boilers. Similar circumstances can arise with blast furnace gas-fired boilers, e.g., during blast furnace relines, tuyere changes, or other temporary outages. It is not clear from the definition of gas-fired boiler whether the terms gas curtailment and gas supply emergencies pertain to commercial natural gas supplies or can be interpreted to include occasions of curtailment and supply deficiencies from the process supplying the gas to the boiler. In the absence of clarifying language in the definition, the occasional use of liquid fuel would place these boilers (as well as any units using any liquid fuel, except in the stated circumstances) into a category that requires stringent emission limits, the installation of costly emission control equipment, and testing, monitoring and recordkeeping obligations.

Comment: AISI requests that EPA provide clarification that boilers firing liquefied petroleum gas (LPG) or propane-derived synthetic natural gas (SNG) as a backup fuel are considered a gas-fired boilers. We note that EPA proposes to incorporate ASTM D183503a to define "natural gas" for purposes of this regulation. It is important that any standard incorporated by the regulation be broad enough to encompass the use of propane (a constituent of LPG) as natural gas and not just mixtures. Most LPG mixtures include butane, which reduces the effectiveness of LPG at low temperatures, causing many facilities to substitute propane. Propane (and/or LPG) is mixed with air to create SNG, which should be specifically allowed to be considered as natural gas for purposes of this rule. LPG-based SNG is often used for emergency backup and EPA should make this point explicit in the final rule.

Comment: EPA should also revise the definitions found on pages 32064-32065 of the Federal Register accordingly:

Minimum pressure drop means 90 percent of the minimum pressure drop during a normal cleaning cycle when operated according to the OEM recommended procedures.
Minimum scrubber effluent pH means 90 percent of at the minimum normal online load. Minimum normal online load shall be defined by the site based on unit load data and approved by the Administrator.
Minimum scrubber flow rate means 90 percent of the test average sorbent ratio during the most recent performance test demonstrating compliance with the applicable emission limit. The minimum sorbent ratio is defined by the site based on the amount and type of sorbent used to scrub acid gases, and may be based on whichever acid gas governs the normal sorbent injection rate (e.g., Ca:SO2, or Na:HCl, etc.). The minimum sorbent ratio must be approved by the Administrator.
Minimum sorbent injection rate means 90 percent of the test average sorbent (or activated carbon) injection ratio for each sorbent measured according to Table 7 to this subpart during the most recent performance test demonstrating compliance with the applicable emission limits. The minimum sorbent ratio is defined by the site based on the amount and type of sorbent used to control emissions, and may be based on appropriate parameters to ensure optimal emissions control (e.g., lb carbon per MMacf, lb carbon per mmBtu heat input, etc.). The minimum sorbent ratio must be approved by the Administrator.

Minimum voltage or amperage means 90 percent of the test average voltage or amperage to the electrostatic precipitator measured according to Table 7 to this
subpart required to comply with Particulate Matter emission limits at the minimum normal online load. Minimum normal online load shall be defined by the site based on unit load data and approved by the Administrator.
Minimum voltage or amperage means 90 percent of the test average voltage or amperage to the electrostatic precipitator measured according to Table 7 to this subpart required to comply with Particulate Matter emission limits at the minimum normal online load. Minimum normal online load shall be defined by the site based on unit load data and approved by the Administrator.

Response: EPA has adjusted the terms in order to account for variable loads at the unit compared to the loads using during the performance test. See the modified definitions in the final rule.

Comment: In the proposed rule EPA is proposing a work practice standard for boilers that burn natural gas or “refinery gas” (see Section III D. of the summary). The Division recommends that instead of identifying specificsources of the gases subject to the work practice requirements, EPA identify those qualities which would make a gas qualify (emission standards, possibly with periodic testing requirements to show that the gas continued to meet the requirements).

Response: EPA has revised the definition of natural gas, consistent with the boiler NSPS definition. Any unit burning any other gaseous fuels other than natural gas or refinery gas must demonstrate that the gases meet the specifications for mercury and H2S content. Please refer to the preamble for discussion of the Gas 1 subcategory work practice standards.

Comment: The definition of a temporary boiler should not be limited to 180 consecutive days because it is inconsistent with well established EPA regulations for other temporary or portable equipment.
The definition of "temporary boiler" in the proposed rule limits the boiler to 180 consecutive days at a location. This definition is inconsistent with the definition in other regulations. Portable equipment is exempt from the requirements of the Mandatory Greenhouse Gas Reporting Rule in 40 CFR §98.30. In 40 CFR §98.6, portable is defined to include equipment is designed and capable of being carried or moved from one location to another (e.g. wheels, skids, carrying handles, dolly, trailer, or platforms) and the equipment resides at the same location for no more than 12 consecutive months. Furthermore, in Section 111(a)(3) of the Federal Clean Air Act, non-road engines defined in 40 CFR §89.2 are exempt from the definition of a stationary source provided that the engine is located on a site for a period of less than 12 consecutive months.
Boiler outages can exceed 6 months or 180 days and may require companies to acquire a temporary rental boiler. These rental boilers are brought onsite while repairs are made to the stationary boiler and are needed on an expedited delivery schedule. It is impractical to incorporate a temporary boiler into the existing control system during this short period.
Therefore, Celanese recommends that the definition of a temporary boiler be revised to allow the use of a temporary boiler onsite for a period of no more than 12 consecutive months, to allow for sufficient time to cover boiler outages and to be consistent with other EPA regulations.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2960.1, Excerpt Number 21 to view the response.
EPA has revised the definition in the final rule to match the definition of "portable" in the GHG reporting rule, as suggested by the commenter.

Comment: EPA seeks to establish a definition for hot water heaters that would distinguish residential-type units or those used for non-process purposes from process-related units.

However, the proposed definition bases the exemption solely on the size and output of the unit by limiting the capacity of an exempted hot water heater to 120 gallons, the pressure to 160 psig, and the temperature to 120 °F.
In order to maintain consistency with the rationale used to exempt hot water heaters, a hot water heater should be distinguished from a boiler by the intended use of its output, not its physical parameters. Accordingly, ACCCI recommends the following revision to the definition in §63.7575:
Hot water heater means a device in which water is heated by combustion of gaseous or liquid fuel and is withdrawn for personal use and not for use in an industrial, commercial, or institutional process.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2998.1, Excerpt Number 46 to view the response.

Comment: The Definition of Hot Water Heater Needs to be Revised

In section IV.A of the preamble to the Proposed Rule, EPA states that the proposal would not regulate hot water heaters as defined in section 63.7575. EPA recognizes that all hot water heaters meet the proposed definition of a boiler because they are enclosed devices that combust fuel for the purpose of heating water, but it is further stated that the when the hot water output from a hot water heater is intended for personal use rather than for use in an industrial, commercial, or institutional process, the hot water heater is more appropriately identified as a residential-type boiler and not an industrial, commercial, or institutional boiler.

EPA seeks to establish a definition for hot water heaters that would distinguish residential-type units or those used for non-process purposes from process-related units. However, the proposed definition bases the exemption solely on the size and output of the unit by limiting the capacity of an exempted hot water heater to 120 gallons, the pressure to 160 psig, and the temperature to 120 degrees F.

In order to maintain consistency with the rationale used to exempt hot water heaters, a hot water heater should be distinguished from a boiler by the intended use of its output, not its physical parameters. Accordingly, AISI recommends the following revision to the definition in section 63.7575:

Hot water heater means a device in which water is heated by combustion of gaseous or liquid fuel and is withdrawn for personal use and not for use in an industrial, commercial, or institutional process.

Response: EPA has revised the definition in the final rule to match the one suggested in this comment.

Commenter Name: Christopher S. Colman
Commenter Affiliation: Hovensa LLC

Comment Excerpt Number: 54

Comment: Proposed Rule Language:
Liquid fuel subcategory includes any boiler or process heater of any design that burns more than 10 percent liquid fuel and less than 10 percent solid fuel, on an annual heat input basis.
Unit designed to burn oil subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent solid fuel on a heat input basis on an annual average, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of
gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not
to exceed a combined total of 48 hours during any calendar year are not included in this definition.
Comment:
It is unclear from these definitions whether a unit that burns ANY oil is subject to regulation as an oil burning unit or whether a 10% threshold applies. As noted in HOVENSA's comments above, HOVENSA disagrees with the technical basis for the 10% threshold.

Response: EPA has revised the definition in the final rule from "oil" to "liquid fuel."

Commenter Name: Traylor Champion
Commenter Affiliation: Georgia-Pacific LLC
Document Control Number: EPA-HQ-OAR-2002-0058-2745.1
Comment Excerpt Number: 64

Comment: EPA has been very consistent throughout the proposal to use 10% as a threshold for movement from one subcategory to another. For example the most stringent – coal – includes units that burn at least 10% coal. The next – biomass – includes units that burn at least 10% biomass and less than 10% coal. The first sentence of the oil (liquid) subcategory includes any liquid fuel, but less than 10 % solid fuel.

Therefore, it logically follows that a plain reading of the Gas 1 subcategory would be that EPA intended to include any unit that burns at least 90% gas and less than 10% of any other fuel. However, the second sentence in the oil (liquid) subcategory emphasized above is in contradiction with the Gas 1 definition by implying that any more than 48 hours (2 days) per year of liquid fuel firing would reclassify the unit into the liquid category.

GP urges EPA to delete the sentence in the definition of an oil (liquid) unit: “Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment, gas supply emergencies or for periodic testing of liquid fuel not to exceed a combined total of 48 hours during any calendar year are not included in this definition”.

Comment: The Definition Of Natural Gas Should Be Revised To Be Consistent With The NSPS Definition The proposed section 63.7575 definition of natural gas includes only the prior NSPS definition, not the 2009 NSPS Subparts Db and Dc revisions. The natural gas definition for this rule needs to be consistent with that rule and should, therefore, also include the following: "(3) A mixture of hydrocarbons that maintains a gaseous state at ISO conditions. Additionally, natural gas must either be composed of at least 70 percent methane by volume or have a gross calorific value between 34 and 43 megajoules (MJ) per dry standard cubic meter (910 and 1,150 Btu per dry standard cubic foot)." The addition of item 3 in the definition allows other gases that are essentially the same as natural gas, such as synthetic natural gas or treated landfill gas, to be included in the definition. It is unnecessary to restrict the definition to only gases from geologic formations. The net impact of this third part of the definition is to promote the beneficial combustion of clean gaseous fuels, such as clean Landfill Gas, which might otherwise be released into the atmosphere or flared.

Comment Excerpt Number: 13

Comment: If the qualification of liquid fuel usage remains in the definition of gas-fired boiler, we suggest adding further clarifying language that is contained in the definition of a waste heat boiler in the Proposed Rule. Waste heat boilers are exempt from the rule. The waste heat boiler definition in the Proposed Rule is limited to units designed to use no more than 50% of the total heat input capacity of the unit with supplemental burners. We believe that the environmental and energy conservation benefits of using coke oven gas are comparable to the use of waste heat or blast furnace gas, both exempted under the Proposed Rule, and that the same provisions for using supplemental fuels should apply to units intended to utilize coke oven gas. Accordingly, applying the same rationale, we urge EPA to modify the gas-fired boiler exemption to include those units designed to use supplemental fuels up to 50% of the total heat input capacity of the unit.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2960.1, Excerpt Number 27 to view the response.

Comment: The Florida Sugar Industry proposes a regulatory definition for “bagasse boiler” as follows:
Bagasse boiler means a hybrid suspension- and grate/floor-fired boiler that is uniquely designed and operated to dry and burn bagasse as its primary fuel. The steam output from the boilers is tied directly to the sugarcane grinding mills, electrical generators, and the raw sugar production process for combined heat and power generation. Bagasse boilers receive bagasse fuel directly and continuously from the sugarcane milling and grinding process. Fuel distributors specially designed for bagasse are used in conjunction with air distributors to
spread the fuel material over the boiler width and depth. The drying and much of the combustion of the fuel takes place in suspension, and the combustion is completed on the grate or floor. Bagasse boilers are universally designed to have high heat release rates and high excess air rates.

Response: Please refer to the preamble for discussion of a combined grate/suspension firing subcategory. This subcategory includes bagasse units however is based on design features, and is not specific to fuel type. Bagasse boilers that have a fuel cell combustor design will be covered under the fuel cell category,

Comment: EPA Should Clarify Definition of Units Burning Single Type of Fuel

Units that burn a single fuel and choose to comply via stack testing are not required to conduct fuel analyses. This exemption from performing fuel analysis is not clear however, because the definition of units burning a single fuel needs to be clarified. Purdue asks that EPA define "units burning a single type of fuel" to include those that burn only one type of solid fuel but use gaseous or liquid fuel as start-up/supplemental fuels.

Purdue’s solid fuel fired boilers cannot start up from a cold condition on their main fuel. In addition, the stokers can co-fire a nominal amount of natural gas during operation for flame stability. These units require an additional fuel source to initiate combustion until such time as the unit is warmed up and stable combustion with the solid fuel can be safely maintained. Whether for startup, short-term flame stability when solid fuel feeding and/or when firing systems are taken in- or out-of-service, or in reaction to unusual conditions, the startup or supplemental fuel is a transient fuel source. The start up or supplemental fuel represents a negligible percentage of the source’s total hours of operation, and thus has a negligible impact on overall emissions from the source.

We support EPA’s intent to exempt units that fire a single type of fuel from the additional burden of conducting fuel analyses during performance stack testing as a reasonable accommodation to minimize unnecessary costs. EPA should clarify its intent in this matter by including language to explain that units which use a start-up fuel for initial startup, units shutdown, or transient flame stability purposes, still qualify as “sources that burn a single type of fuel” and are exempt from the fuel analysis requirements under §63.7521 and Table 6.

EPA should further clarify that solid fuel units that fire Natural Gas or Commercial Fuel Oil as a supplementary or start up fuel are likewise considered “sources that burn a single type of fuel” and are exempt from the fuel analysis requirements under §63.7521 and Table 6.

Response: Please refer to the preamble for discussion of startup/shutdown changes. Revised 63.7510(a) to add that sources using a second fuel for only start up, shut down, and transient flame stability are still considered units burning a single fuel.

Comment: Define Maximum Normal Operating Load

The EPA proposes that facilities conduct yearly performance tests for the first three years for affected sources that elect to demonstrate compliance with any of the emission limits through performance testing. Facilities could establish an every three-year schedule if the performance tests for the pollutant show that emissions are at or below 75 percent of the emission limit for at least 3 consecutive years. This reduced testing option does not apply to performance tests for dioxin/furan or if the facility elects to demonstrate compliance using the emission averaging option.

The EPA proposes that affected sources conduct performance tests at the "maximum normal operating load." However, this maximum normal operating load is not defined in the proposed rule. Facilities use different fuels depending on many variables such as availability and cost. Fuels are also combusted in different proportions throughout the year. The EPA should provide a clear definition of maximum normal operating load in 63.7575. The EPA should also clearly define how a source that utilizes more than one fuel should comply with this requirement. Having this clearly defined is necessary not for only determining compliance with the emission standards, but also for adequately approving site-specific test plans that would be required in 63.7520.

Response: EPA has revised the final rule by replacing "maximum operating load" with "representative operating load conditions."

Comment: Define Approved Specialist

In 63.7575, a tune-up is defined as "adjustments made to a boiler in accordance with procedures supplied by the manufacturer (or an approved specialist) to optimize the combustion efficiency". "Approved specialist" must be defined in order to determine who can establish procedures to optimize the combustion efficiency in absence of manufacturer’s recommendations. We believe the EPA should retain the authority to determine whether an individual qualifies as an "approved specialist" and should provide a clear process for these individuals to be approved.

Response: EPA has removed the definition of "Tune up", so "Aaproved specialist" definition is not needed.

Comment: The proposed standard at 63.7520(c) requires that performance tests be conducted at “the maximum normal operating load….”. However, “normal” is not defined in the proposed standard. In the absence of a definition, “normal” can mean almost anything to an owner/operator, or to a regulatory agency. To insure that tests are conducted under reasonably consistent operating conditions across the regulated boiler universe, EPA should define “normal” to mean “between 90% and 110% of the average operating rate during the preceding 12 months.” Because some state agencies ordinarily require operating boilers at or near capacity, conducting full-load emission tests on boilers that normally operate at sub-capacity loading will be non-representative of truly normal conditions on that boiler.

Comment: EPA should use consistent terminology and define terms where necessary in the final rule.

In the proposed rule, EPA uses three different terms in providing details on how to properly categorize a regulated boiler into the proper subcategory:

-In the preamble(§III.D, page 32012): "If your new or existing boiler or process heater burns gaseous fuel and less than 10 percent, on an annual average heat input basis, of liquid or solid fuel, we are proposing that the unit is in one of the gas subcategories."
This phrase "annual average heat input basis" is also used in the preamble when defining the other source categories.

-In §63.7575, the proposed definitions for units designed to burn biomass, coal, gas I (NG/RG) and oil use the phrase "heat input basis on an annual average".

-In §63.7575, the proposed definition for liquid fuel subcategory uses the phrase "annual heat input basis."

If the term -annual average heat input basis" is chosen, EPA should define or explain the term. We believe that EPA intends for this determination to be done for a calendar year thus the term "average" could be misleading. If the intent is for facilities to average fuel use over multiple years, then EPA should specify the number of years to include in the average.

Recommend EPA adopt the term "annual heat input basis" for consistent use throughout the rule.

Comment: INVISTA requests that EPA further clarify the meaning of the phrase “heat input basis on an annual average.” As currently drafted, the language could be interpreted to mean a subject facility would have to calculate the annual average each year, which is inconsistent with similar requirements in existing Clean Air Act regulations. For example, the New Source Performance Standards, Subpart Db, uses the term “annual capacity factor” to limit the applicability of an emission limit, which is nearly an identical purpose to the use of the “heat input basis on an annual average” term in the above definition. See 40 CFR 60.42b(f). The meaning should be clarified in this proposed regulation by adopting the same approach.

Specifically, EPA should define “annual capacity factor” and replace the phrase “heat input basis on an annual average.” INVISTA proposes the following text:

Recommended Text in 63.7575, Definitions:
Annual capacity factor means the ratio between the actual heat input to a unit subject to this subpart, as applicable, during a calendar year and the potential heat input to the unit had it been operated for 8,760 hours during a calendar year at the maximum steady state design heat input capacity. In the case of units that are rented or leased, the actual heat input shall be determined based on the combined heat input from all operations of the affected facility in a calendar year.

Unit designed to burn gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas with at least a 90 percent annual capacity factor on a heat input basis on an annual average.

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that burns gaseous fuels other than natural gas and/or refinery gas not combined with any solid or liquid fuels at less than a 10 percent annual capacity factor.

Response: EPA has revised the final rule language in multiple areas to clarify when heat input is is needed as an average, a fraction or percent, or as the total input.

Comment: Boilers and process heaters that use natural gas or refinery gas as fuel are subject to different requirements from units that use other gases. If this situation remains in the final rule, refinery gas needs to be defined. We recommend the following definition, which we feel is most likely to reflect the fuels fired by the units identified as firing refinery gas in the rulemaking database.

Refinery gas means any gas which is generated at a petroleum refinery and which is combusted. Refinery gas includes natural gas when the natural gas is combined and combusted in any proportion with a gas generated at a refinery. Refinery gas includes gases generated from other facilities when that gas is combined and combusted in any proportion with gas generated at a refinery.

Including gases from contiguous and nearby facilities reflects the real situation at many refineries, where adjoining petrochemical operations, natural gas plants, terminal operations, third party hydrogen plants, electric utility plants, etc. have common fuel gas systems with a refinery. This is consistent with the definition of fuel gas in the Refinery 1 NESHAP (Part 63 Subpart CC).

The fact that this definition is meant to include gases from adjoining operations was made clear in the Final Background Information Document for Subpart CC, where EPA states the following in response to comments received. [Footnote: US EPA, Emission Standards Division, National Emission Standards for Hazardous Air Pollutants, Petroleum Refineries Background Information for Final Standards, Summary of Public Comments and Responses, EPA-453/R-95-015b, July 1995]

On page 5-41[A1]

Response: The EPA agrees that refineries and petrochemical plants with a common fuel gas system should be accounted for in the definition of fuel gas system. The EPA contents that this is accomplished with the wording “offsite and onsite piping and control system”. The reference to “external sources of natural gas or liquefied petroleum gas” was meant to include in the definition other sources of gas, such as natural gas or liquefied petroleum gas, supplied by a vendor. It is not intended as a reference to adjacent petrochemical plants. However, the words underlined by the commenter have been deleted to avoid confusion. The EPA contends that the definition does not exclude fuel gas systems associated with petrochemical plants.

On Page 5-42
Response: The EPA agrees that it should be recognized that refineries may share a fuel gas system with an adjacent non-refinery plant. This is accomplished in the definition of fuel gas-system, which includes the “offsite and onsite piping control system.” The EPA contends that it is not necessary to revise the definition of refinery fuel gas. The definition of miscellaneous process vents excludes “gaseous streams to a fuel gas system.” It is in the definition of fuel gas system that the inclusion of petrochemical and other facilities must be made.

Recommendation: Add a definition of refinery gas as suggested herein.

Response: EPA has revised the final rule to include a definition of refinery gas as suggested by the commenter.

Comment: EPA Should Clarify Definition of Units Burning Single Type of Fuel.
Units that burn a single fuel and choose to comply via stack testing are not required to conduct fuel analyses. 75 FR 32051. This exemption from performing fuel analysis is not clear and the definition of units burning single fuel needs to be revised. CIBO recommends that EPA define "units burning a single type of fuel" to include those that burn only one type of solid fuel but use gaseous or liquid fuel as start-up/supplemental fuels.

Most solid fuel boilers cannot start up from a cold condition on their main fuel. Such units require an additional fuel source to initiate combustion until such time as the unit is warmed up and stable combustion with the solid fuel can be safely maintained. For example, pulverized coal fired boilers typically start up by firing either Natural Gas or Fuel Oil. Startup periods typically last from several hours (e.g. stoker coal or pulverized coal boilers) to several days (e.g. large circulating fluidized bed boilers), per OEM recommendations, during which time coal combustion is started. When certain OEM specified conditions are met (e.g., minimum steam temperature, minimum tube temperature, minimum flue gas temperature, minimum pulverizer temperature, elapsed time from light-off, etc.), the start up fuel is shut down and the unit fires coal exclusively. Some pulverized coal units have additional OEM specified flame stability controls that require the start up fuel to be fired on specific burners when a pulverizer is either being removed from service or put into service (e.g., typical pulverized coal fired boilers). Solid fueled units can also utilize the startup fuel to preserve unit capacity due to an unforeseen malfunction in the solid fuel feeding and/or firing system(s). Whether for startup, short-term flame stability when solid fuel feeding and/or firing systems are taken in- or out-of-service, or in reaction to unusual conditions, the startup or supplemental fuel is a transient fuel source. The start up or supplemental fuel represents a negligible percentage of the source’s total hours of operation, and thus has a negligible impact on overall emissions from the source. For example, if a source operates continuously on coal for 49 weeks per calendar year; and has three start ups per year, each of which requires firing Natural Gas for 8 hours; the annual source operating time on Natural Gas equals (3 x 8 hours = 24 hours) divided by (49 weeks x 7 days per week x 24 hours per day = 8,232 hours) equaling 0.3% of the source’s operating hours on the startup fuel. The percentage of operating hours with supplemental fuel will necessarily vary based on unit design, operating characteristics, fuel quality, and other issues.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2782.1, Excerpt Number 10 to view the response.

Comment Excerpt Number: 244

Comment: Proposed 63.7555(d)(3) requires “You must keep records of monthly hours of operation by each boiler or process heater. This requirement applies only to limited-use boilers and process heaters.” “Limited-use” is not a defined term. We presume this means boilers and process heaters that do not normally operate, but only operate intermittently. Thus, units that operate in standby mode, i.e., at low rates until needed, would not be “limited use” units. Additionally, it should be clarified that occasional outages for maintenance, production adjustments, etc, do not make a unit “limited use.”

Recommendation: Clarify the meaning of “limited use” as discussed above.

Response: Please refer to the preamble for discussion of the limited-use subcategory. EPA adapted the definition of “limited use solid fuel subcategory” from 2004 vacated rule to read as follows: Limited-use boiler or process heater means any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable annual average capacity factor of no more than 10 percent.

Comment Excerpt Number: 86

Comment: We support EPA’s intent to exempt units that fire a single type of fuel from the additional burden of conducting fuel analyses during performance stack testing as a reasonable accommodation to minimize unnecessary costs. EPA should clarify its intent in this matter by including language to explain that units which require a start-up fuel for initial startup, units shutdown, or transient flame stability purposes, still qualify as "sources that burn a single type of fuel" and are exempt from the fuel analysis requirements under §63.7521 and Table 6.

EPA should further clarify that solid fuel units that fire Natural Gas or Commercial Fuel Oil as a supplementary or start up fuel are likewise considered "sources that burn a single type of fuel" and are exempt from the fuel analysis requirements under §63.7521 and Table 6.

Response: The rule has been revised to consider units that use supplementary fuel only for startup, shutdown, and flame stability are still considered to burn only a single fuel. Please refer to the preamble for discussion of startup/shutdown changes.

Comment: Based on 63.1(a)(10) of part 63 subpart A, a day is a calendar day unless otherwise specified. Thus we assume the 30-day rolling average specified for CO from boilers and process heaters ?100 MMBTU/hr means an average must be calculated once per day for the 30 calendar day period ending at midnight of the previous day. It would be wasteful and add no value to require more frequent calculations than that, since the intent is to average the CO emissions over 30 days.

Recommendation: Clarify that the CO 30-day rolling average is based on 30 calendar days.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2863.1, Excerpt Number 51 to view the response.
EPA has removed the 30-day rolling average compliance mechanism from the final rule. We have also added a definition of operating day in the final rule.

Comment: The term refinery gas is not a defined term in the proposed MACT rule for boilers and heaters. However, a definition of Refinery Fuel Gas is published in 40 CFR 63.641 as follows:

Refinery Fuel Gas means "a gaseous mixture of methane, light hydrocarbons, hydrogen, and other miscellaneous species (nitrogen, carbon dioxide, hydrogen sulfide, etc.) that is produced in the refining of crude oil and/or petrochemical processes and that is separated for use as a fuel in boilers and process heaters throughout the refinery."

In conjunction with the definition of "Unit Designed to Burn Gas 1 (NG/RG)", Dow suggests the following definition to add to the regulatory text in Section 63.7575:

Refinery Gas and Off-Gas Streams from Petrochemical and Chemical Plant processes - means "a gaseous mixture of methane, light hydrocarbons, hydrogen, and other miscellaneous species (nitrogen, carbon dioxide, hydrogen sulfide, etc.) in the refining of crude oil or in the production of chemicals or petrochemicals and that is separated for use as a fuel in boilers and process heaters throughout the site.

Comment: A determination of whether an emission unit is equipped with a dry control system is one of the steps in determining compliance requirements pursuant to proposed §63.7541(a)(2). The definitions in 63.7575 do not include a definition of "dry control system". The definitions do include "dry scrubber", "electrostatic precipitator", and "fabric filter", but do not define each of

those control techniques to be a "dry control system". EPA should clarify the rule by changing the definitions as follows (additions underlined in bold):
Dry scrubber means an add-on air pollution control system that injects dry alkaline sorbent (dry injection) or sprays an alkaline sorbent (spray dryer) to react with and neutralize acid gas in the exhaust stream forming a dry powder material. Sorbent injection systems in fluidized bed boilers and process heaters
are included in this definition. A dry scrubber is a dry control system.
Electrostatic precipitator means an add-on air pollution control device used to capture particulate matter by charging the particles using an electrostatic field, collecting the particles using a grounded collecting surface, and transporting the particles into a hopper. An electrostatic precipitator is a dry coritroi system.
Fabric filter means an add-on air pollution control device used to capture particulate matter by filtering gas streams through filter media, also known as a baghouse. A fabric filter is a dry control system.

Response: EPA has added to the final rule that dry scrubbers, ESP, and FF are "dry control systems."

Comment: EPA Should include a definition for “refinery gas” since units fired with refinery gas are included in the Gas 1 subcategory definition (63.7575). OCC noted that two refineries in the rulemaking database are firing 100% hydrogen. The fuel gas definition should include hydrogen generated by chemical manufacturing facilities in a manner similar to how fuel gas systems are addressed in the refinery MACT. This is consistent with the definition of fuel gas in the Refinery 1 NESHAP (Part 63, Subpart CC). In that standard, “refinery fuel gas” and “refinery fuel gas system” are defined as follows: “Refinery fuel gas means a gaseous mixture of methane, light hydrocarbons, hydrogen, and other miscellaneous species (nitrogen, carbon dioxide, hydrogen sulfide, etc.) that is produced in the refining of crude oil and/or petrochemical processes and that is separated for use as a fuel in boilers and process heaters throughout the refinery.”

Comment: EPA Should Define Maximum Normal Operating Load. The proposed standard at section 63.7520(c) requires that performance tests be conducted at "the maximum normal operating load...." However, "normal" is not defined in the proposed standard. In the absence of a definition, "normal" can mean almost anything to an owner/operator, or to a regulatory agency. To insure that tests are conducted under reasonably consistent operating conditions across the regulated boiler universe, EPA should define "normal" to mean "between 90% and 110% of the average operating rate during the preceding 12 months." Because some state agencies ordinarily require operating boilers at or near capacity, conducting full-load emission tests on boilers that normally operate at sub-capacity loading will be nonrepresentative of truly normal conditions on that boiler.

Comment: If Refinery Gas Will Be Regulated Separately From Other Gases In The Final Rule, EPA Should Include A Definition Of Refinery Gas. Units that use refinery gas as fuel are subject to different requirements under the proposed rule from units that fire "other gases" (Gas 2). If this situation remains in the final rule, refinery gas needs to be defined. We recommend the following definition, which we feel is most likely to reflect the fuels fired by the units identified as firing refinery gas in the rulemaking database.

Refinery gas means any gas which is generated at a petroleum refinery and which is combusted. Refinery gas includes natural gas when the natural gas is combined and combusted in any proportion with a gas generated at a refinery. Refinery gas includes gases generated from other facilities when that gas is combined and combusted in any proportion with gas generated at a refinery.

Including gases from contiguous and nearby facilities reflects the real situation at many refineries, where adjoining petrochemical operations, natural gas plants, terminal operations, third party hydrogen plants, electric utility plants, etc. have common fuel gas systems with a refinery. This is consistent with the definition of fuel gas in the Refinery 1 NESHAP (Part 63 Subpart CC). In that standard, refinery fuel gas and refinery fuel gas system are defined as follows.

Refinery fuel gas means a gaseous mixture of methane, light hydrocarbons, hydrogen, and other miscellaneous species (nitrogen, carbon dioxide, hydrogen sulfide, etc.) that is produced in the refining of crude oil and/or petrochemical processes and that is separated for use as a fuel in boilers and process heaters throughout the refinery.

Fuel gas system means the offsite and onsite piping and control system that gathers gaseous streams generated by refinery operations, may blend them with sources of gas, if available, and transports the blended gaseous fuel at suitable pressures for use as fuel in heaters, furnaces, boilers, incinerators, gas turbines, and other combustion devices located within or outside of the refinery. The fuel is piped directly to each individual combustion device, and the system typically operates at pressures over atmospheric. The gaseous streams can contain a mixture of methane, light hydrocarbons, hydrogen and other miscellaneous species.

The fact that this definition is meant to include gases from adjoining operations was made clear in the Final Background Information Document for Subpart CC [US EPA, Emission Standards Division, National Emission Standards for Hazardous Air Pollutants, Petroleum Refineries – Background Information for Final Standards, Summary of Public Comments and Responses, EPA453/R-95-015b, July 1995].

Document Control Number: EPA-HQ-OAR-2002-0058-3213.1
Comment Excerpt Number: 224

Comment: EPA has described energy assessments in the preamble as a Beyond-The-Floor option, meaning a control option more stringent than the MACT floor that could achieve greater emissions reductions. EPA has clearly written in the preamble that these energy assessments are considered to represent controls "beyond the MACT floor."
However, in Table 3 of the rule EPA lists energy assessments as a Work Practice Standard. The Clean Air Act describes Work Practices in §112(h) as an alternative to an emission standard when it is not feasible to prescribe or enforce an emission standard.
Because energy assessments are presented in this proposed rule as a standalone requirement for all facilities, rather than an alternative to meeting a proposed emission standard, the proposed energy assessments do not appear to meet the intent of §112(h) of the Clean Air Act as a Work Practice. EPA should resolve this inconsistency and remove energy assessments from Table 3.

Response: EPA acknowledges the comment but no changes, mentioned in this comment, have been made to Table 3 within the final rule. Please refer to the preamble for discussion of EPA's authority to require energy audit and energy audit requirement changes which are referred to as a beyond-the-floor standard.

Comment Excerpt Number: 325

Comment: Table 9 of the rule requires startup, shutdown, and malfunction reports if facilities have SSM events not consistent with the SSM plan and there were excess emissions. However, as EPA has proposed that the standards apply at all times with no SSM exemption and Table 10 states that the SSM provisions and plan requirements in the Part 63 General Provisions do not apply, the SSM reporting requirement in Table 9 should be removed.

Response: EPA has removed SSM requirements from Table 9 within the final rule. New language was included in the rule to address SSM events.

Comment: General Cross Reference Issues
In order to ensure correct interpretation of the regulation, NHDES is noting the following typographical errors that should be corrected prior to finalization of the proposed regulation. First, §63.11201 does not reference the Table 3 mercury standards but Table 3 references §63.11201. Second, the language preceding Table 2 refers to §§63.11202 and 63.11203 but should reference §63.11201. Finally, Table 3 refers to §63.11211(c) but should be §63.11211 (b).

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-3212.1, Excerpt Number 322 to view the response.

Comment: Clarification is requested on the Table 3 nomenclature. The table in places refers to “boilers” and in other places to “boilers & process heaters”. Does EPA intend to include both categories in these work standards?

Response: In Table 3, the work practices in items 1 and 2 apply to both boilers and process heaters; in item 3, they apply only to boilers.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 10

Comment: The applicability of the work practice requirements in the proposal is unclear because Table 3 in the proposed rule is unclear.

The heading in column 1 refers to boilers, but Items 1 and 2 in that column refer to boilers and process heaters, while the requirements in column 2 mention only boilers. The preamble discussion and related regulatory language seems to apply the tune-up requirement to both boilers and process heaters and the energy assessment requirement to facilities with boilers. However, the proposed definition of energy assessment in proposed 63.7575 refers to both boilers and process heaters.

Recommendation: Clarify the applicability of the tune-up requirement and the energy assessment requirement and revise Table 3 and the definition of "energy assessment" accordingly. Make all of the Table 3 language consistent.

Response: Both are applicable and EPA has revised Table 3 within the final rule to clarify this.

Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 103

Comment: Limits Should be Corrected.
The Proposed Rule includes CO emission limits for solid fuel burning units "corrected to 3 percent oxygen." 75 FR 32066-67. In the final rule, EPA should amend the CO limits so that they are corrected to 7 percent oxygen, just as the dioxin/furan limits are. This is appropriate as 7 percent oxygen is generally a more common operating level for units burning solid fuels. Furthermore, the Proposed Area Source Rule includes CO emission limits corrected to 7 percent oxygen. 75 FR 31932.

Response: EPA reconized the comment however, Table 1 and 2 limits for CO within the final rule are still at 3% oxygen for all fuels. EPA has retained the oxygen correction of 3 percent in the final rule for CO. Units with other oxygen corrections can adjust the measured value with a simple calculation.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-2702.1
Comment Excerpt Number: 104

Comment: The dioxin/furan emission limits for liquid and Gas 2 is currently corrected to 7 percent oxygen. 75 FR 32067. The dioxin/furan emission limit for liquid and Gas 2 should be corrected to 3 percent oxygen, just as oxygen is listed for CO for those fuels. This is appropriate as 3 percent oxygen is generally a more common operating level for liquid and gaseous fuels. Furthermore, the Proposed Area Source Rule includes dioxin/furan emission limits corrected to 3 percent oxygen. 75 FR 31932. Overall, CIBO recommends that EPA establish all emission corrections for a particular fuel corrected to the same oxygen level.

Response: EPA reconized the comment however, Table 1 and 2 limits for D/F within the final rule are still at 7% oxygen for all fuels. EPA has retained the oxygen correction of 7 percent in the final rule for dioxin/furans. This is consistent with how data was requested in the Phase II ICR survey, and units with other corrections can adjust the measured value with a simple calculation.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 180

Comment: Table 7 requires establishing separate operating parameter limits for pressure drop and liquid flow for wet scrubbers for HCl and for PM and Hg. Proposed 63.7530(c)(3)(i), on the other hand, requires that you establish one set of operating limits for these parameters using the maximum values from either the PM/Hg performance test or the Cl- performance test. Since you would have to meet the maximum values during operations, it makes no sense to establish two limits and Table 7 should be modified to match 63.7530(c)(1)(i).

Recommendation: Modify Table 7 wet scrubber requirements to match those in 63.7530(c)(1)(i)

Response: EPA acknowledges the comment but no change mentioned within this comment is needed for Table 7. The rule already specifies in 63.7530(b)(3)(i) that one set of operating parameters is needed for a wet scrubber that controls PM and HCl, and Table 7 references 63.7530(b) for settng the operating limits for both PM and HCl.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 192

Comment: Proposed Table 6 specifies the methods to be used for fuel analysis. However, the Table only addresses coal and biomass. Reasonable procedures for gases and liquids are needed. For gas streams, fuel BTU content is typically determined using gas chromatography to identify the bulk of the constituents in the gas and then calculating the heat content from published component heat capacities. In some cases, sources even have on-line analyzers that continuously determine the heat content. These approaches to determining the heat content of gases should be specifically included in Table 6.

Recommendation: Revise Table 6 to include liquid and gas methodologies.

Response: The final rule provides for an "or equivalent" option for affected sources to obtain approval for additional methods. At this time, the Agency has finalized this approach in lieu of naming specific methods in the final rule.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 241

Comment: Table 9 Item 1.a calls for including in the compliance report Information required in 63.7550(c)(1) through (11). However, there are only 9 subparagraphs to 63.7550(c) so this reference needs to be corrected.

Recommendation: Correct the paragraph references in Table 9 Item 1.a.

Response: EPA has revised the reference to match the final rule [(c)(1) to (10)].

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 242

Comment: Table 9 Item 1.c states, relative to the compliance report, If you have a deviation from any emission limitation (emission limit and operating limit) or work practice standard during the reporting period, the report must contain the information in 63.7550(d). If there were periods during which the CMSs, including continuous emissions monitoring system, continuous opacity monitoring system, and operating parameter monitoring systems, were out-of-control, as specified in 63.8(c)(7), the report must contain the information in 63.7550(e). 63.7550(d) lists information required for a deviation where there is no CMS in use, while 63.7550(e) lists information required for a deviation where there is a CMS in use. CMS out-of-control periods are reportable under 63.8, but are not the only deviations that are reportable under 63.7550(e).

Recommendation: Revise Table 9 to match the requirements in 63.7550(d) and (e).

Response: EPA has revised Table 9 within the final rule to match the language in 63.7550(d) and (e). 1.c. was split into c. and d.

Comment Excerpt Number: 243

Comment: Tables 9 require sources to have SS&M plans and to report on their compliance with those plans and to file immediate reports if they did not follow their plans if there are excess emissions. Table 10 and the rule do not apply SS&M plan requirements, since the proposal applies all requirements during S&S periods and malfunctions are violations. Thus, SS&M plans serve no purpose and SS&M reporting requirements are covered by the normal deviation reporting. These requirements should be removed from Table 9. If, as we recommended earlier, certain startups and shutdowns are covered by a special work practice requirement that work practice, which might involve an S&S plan, would be the only time such a plan should apply and therefore is the only time such a plan is needed.

Recommendation: Delete the SS&M related requirements from Table 9 unless SS&M provisions are added to the final rule.

Response: EPA has removed SSM requirements from Table 9 within the final rule. New language was included in the rule to address SSM events.

Comment: Table 3 — MACT floor for organic HAPs. Table 3 has more subcategories than Table 2. Table 2 has only 4 subcategories while Table 3 has 9. EPA should be consistent in unit subcategorization.

Response: EPA acknowledges the comment but no change is needed because work practices are determined by different criteria than the subcategories for numerical emission limits.

Commenter Name: David M. Kiser
Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 17

Comment: The proposed dioxin/furans limits are at or below the test method detection level (for some labs) and there is confusion in the language of proposed test methods – what can't be measured effectively can't be studied effectively as a practical matter.

EPA proposed dioxin/furan limits in the form of Toxic Equivalents (TEQ) but did not propose nor provide guidance on a standard TEQ methodology, thus determination of compliance or non-compliance with the proposed TEQ standard is not possible even apart from the sensitivity of test methodology and setting the standard near the detection level. TABLE 5 TO SUBPART DDDDD OF PART 63—PERFORMANCE TESTING REQUIREMENTS, 75 Fed. Reg. 32006, 32069-32070 (June 4, 2010), listed no method for determining the emission concentration of Dioxin/Furan as ng/dscfm (TEQ) corrected to 7% oxygen – the location in the table was a "blank".

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2777.1, Excerpt Number 17 to view the response.

Comment Excerpt Number: 51

Comment: The references in Table 4 of the proposed rule (for wet scrubber control) appear to be incorrect. All references in tables should be checked and corrected accordingly.

Response: EPA has updated the final rule to correct reference errors.

Commenter Name: David M. Kiser
Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 52

Comment: Table 4 in the proposed rule appears to have omitted the requirement to monitor pH as specified by section 63.7530(b)(3)(i).

Table 8 in the proposed rule should list the PM CEMS for a boiler with a heat input capacity of 250 MMBtu per hour or greater required to install a PM CEMS under section 63.7525(b). As previously stated, International Paper does not support the use of PM CEMS.

Response: EPA has revised Table 4 to include pH for wet scrubbers. The PM CEMS was not added to Table 8 because the requirements are spelled out completely in the rule text.

Commenter Name: David M. Kiser
Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 53

Comment: Table 8 in the proposed rule should list the CO CEMS for a boiler with a heat input capacity of 100 MMBtu per hour or greater required to install a CO CEMS under section 63.7525(a).

Response: EPA acknowledges the comment but no change, mentioned in this comment, is needed to Table 8. All of the continuous compliance requirements for CO CEMS are in 63.7525(a).

Commenter Name: David M. Kiser
Commenter Affiliation: International Paper Company
Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 56

Comment: Table 3 of the proposed rule should clarify that the energy assessment is a “onetime” energy assessment. The word “one-time” should be inserted in Table 3, i.e., “You must meet the following ... Must have “a one-time” energy assessment performed on the major source facility by qualified personnel which includes”. The one-time assessment is mentioned in the preamble at 75 FR 32012 and 32026 but not in the rule. As previously stated, International Paper does not support the requirement for all major sources to conduct a one-time energy assessment.

Response: EPA has revised Table 3 within the final rule to indicate it is a one-time requirement.

Comment: Proposed Table 9 refers to a startup, shutdown, and malfunction plan that is not required elsewhere in the rule. 75 Fed. Reg. at 32,073.

Response: EPA has removed the SSM requirements from Table 9 within the final rule. New language was included in the rule to address SSM events.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 220

Comment: The Proposed Rule Includes an Ambiguous Classification of the Energy Assessment as Both a Beyond the Floor and Work Practice Standard. The proposed rule includes an ambiguous classification of an energy assessment as both a beyond-the-floor control technology and a work practice standard. This ambiguous classification needs to be resolved. In the proposed rule EPA states that "we believe that an energy assessment is an appropriate beyond-the-floor control technology because it is one of the measures identified in CAA section 112(d)(2)." Also in the proposed rule in Table 3 to Subpart DDDDD of Part 63, EPA proposes to require that an existing boiler must comply with the work practice standards in the table, of which an energy assessment is included.

EPA has described energy assessments in the preamble as a beyond-the-floor option, meaning a control option more stringent than the MACT floor that could achieve greater emissions reductions.

The Clean Air Act describes Work Practices in section 112(h) as an alternative to an emission standard when it is not feasible to prescribe or enforce an emission standard.

The proposed rule would require an energy assessment for all affected facilities, rather than as an alternative to meeting the proposed emission standards. As such, energy assessments do not meet the intent of Section 112(h) of the Clean Air Act as a Work Practice. EPA should resolve this inconsistency.

Response: EPA acknowledges the comment but no changes to Table 3, suggested by the commenter, have been made within the final rule. Please refer to the preamble for discussion of EPA's authority to require energy audit and energy audit requirement changes which are referred to as a beyond-the-floor standard.

Comment: Emissions Averaging

Equations 1 through 4 appear to have an error. The "+" sign should be a "divided by" sign.

Compliance should be based on the actual unit heat input per Equation 3 rather than the maximum heat input per Equation 1.

Continuous compliance, § 63.7S41(a)(1) says to use Equations 3 (or 4) and 5. What is the purpose of Equation 1?

Response: Divisions signs are already in the equations and were published. In Equations 1 and 2, the max rated heat input is used because these are for an initial compliance demonstration. In equations 3 and later, actual heat input is used because these are for ongoing compliance after data have been collected. Text around these equations has been revised to clarify the difference.

Comment: Recordkeeping § 63.7555
The proposed rules specify in paragraph (d)(3) to keep records of monthly hours of operation by each boiler or process heater. This applies to "limited use boilers and process heaters". Where is "limited use boilers and process heaters" defined? What provisions of the rules are not applicable to "limited use boilers and process heaters?"

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2757.1, Excerpt Number 2 to view the response.

Comment Excerpt Number: 2

Comment: Recommendation: Clarify that existing boilers <10 MMBTU/hr do not have to conduct emissions
tests.

Based on Table 2 in subpart DDDDD, emission limits only apply to units 10 MMBTU/hr or higher. Work practices in Table 3 apply to units below that level. The compliance demonstration language in s. 63.7505(c) states "…You must comply with all other applicable limits [emphasis added] using performance stack testing or the compliance monitoring system where applicable."

Language could be included in s. 63.7505(c) to indicate that where no emission limit applies, a unit must comply only with work practice standards and no emissions testing is required. Alternately, that paragraph could be more specific to "applicable limits listed in Table 2" to clarify where testing or CMS apply.

Response: EPA has revised 63.7505(c) to indicate that performance stack testing is needed only if subject to an applicable emission limit listed in Table 2.

Commenter Name: Myra H. Glover

Document Control Number: EPA-HQ-OAR-2002-0058-2757.1
Comment Excerpt Number: 2

Comment: In addition, Entergy would like to request clarification on what appears to be an inconsistency within the proposed rule regarding limited-use boilers and process heaters. Proposed § 63.7555(d)(3) (recordkeeping) states that it applies to "limited-use boilers and process heaters," but EPA has not defined the term "limited-use boilers" and has not used that term elsewhere in the Proposed Rule. If it is necessary for EPA to state that § 63.7 555(d)(3) applies specifically to "limited-use boilers," then it stands to reason that EPA has created this subcategory of boilers -called "limited use" -to which the remainder of the Proposed Rule does not apply. EPA should clarify this point by establishing a definition of "limited-use boilers." As stated above, Entergy proposes that the definition include boilers with an operation of no more than 500 hours per year.

Response: Please refer to the preamble for discussion of the limited-use subcategory. EPA added provisions to exempt limited-use boilers from the emission limits, added hour/year monitoring and kept recordkeeping.

Comment: Clarify Deadline To Establish Emission Caps To Demonstrate Compliance With The Emission Averaging Option For The Emission Level Or Control Technology

In 63.7522(c), the emission rate achieved during the initial compliance test for the HAP associated with an existing boiler or process heater in the averaging group must not exceed the emission level that was being achieved on [THE DATE 30 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER] or the control technology employed during the initial compliance test must not be less effective for the HAP being averaged than the control technology on [THE DATE 30 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER]. However, it is proposed in 63.7522(g)(2)(i) that information associated with the applicable HAP emission level or the control technology installed as of [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE FEDERAL REGISTER] be included in the required emission's averaging plan. This appears to be a contradiction in dates and should be corrected in the final rule.

Response: EPA has updated 63.7522(c) in the final rule to be 60 days also.

Comment: Errors In Performance Tests Language

In 63.7522(j)(2), the EPA proposes that, "If affected units from nonaffected units vent to the common stack, the units from nonaffected units must be shut down or vented to a different stack during the performance test)...." (75 FR 32055). There appears to be several grammatical errors in this clause: It is unclear as to how one can have "affected units from nonaffected units." Perhaps the intention of the EPA was to have included the conjunction "and" between the units described which would provide clarity. Also, the missing parenthesis at the end of the quoted clause suggests that relevant information may have been omitted.

Response: EPA has revised the language within the final rule as the commenter suggested.

Comment: Clarify Requirement To Submit An Implementation Plan For Emission Averaging Compliance Option

There is a contradiction in 63.7522(g)(1). This section mandates the submittal of an implementation plan by using the word "must." However, 63.7522(g) seems to indicate that submittal of the implementation plan is only necessary "upon request." This apparent discrepancy should be corrected in the final rule to avoid confusion.

Response: EPA has removed "upon request" from (g) within the final rule for clarification.

Comment Excerpt Number: 11

Comment: Correct Reference To Representative Operating Conditions In 63.7522(g)(2)(vii)

In 63.7520(c), performance tests must be conducted at the maximum normal operating load. However, 63.7522(g)(2)(vii) requires demonstration of compliance with each of the applicable emission limit(s) to be achieved under representative operating conditions. It appears the EPA used the original Boiler MACT language and did not replace it with maximum normal operating load which needs to be clearly defined in 63.7575.

Response: EPA has replaced maxium normal operating load within the rule to "representative operating conditions."

Document Control Number: EPA-HQ-OAR-2002-0058-2759.1
Comment Excerpt Number: 13

Comment: The proposed § 63.7505(c) refers to § 63.7530(d) for fuel analysis calculations. Section 63.7505(c) should refer to § 63.7530(c).

§ 63.7505(c) You can demonstrate compliance with the applicable emission limit for HCl or mercury using fuel analysis if the emission rate calculated according to § 63.7530(d) is less than the applicable emission limit. Otherwise, you must demonstrate compliance for HCl or mercury using performance stack testing. You must demonstrate compliance with all other applicable limits using performance stack testing, or the continuous monitoring system (CMS) where applicable.

§ 63.7530(d) If you own or operate an existing unit with a heat input capacity of 10 million Btu per hour or less, you must submit a signed statement in the Notification of Compliance Status report that indicates that you conducted a tune-up of the unit.

Response: EPA has updated the final review to correct typos. The reference was corrected to 63.7530(c) because you can only use fuel analysis if the HCL or Hg input is less than the emission limit. Otherwise, you need to use add-on controls and use a stack test to demonstrate compliance.

Comment: Clarify Reduction In Performance Testing Frequency Based On Percentage Of The Emission Limit

In 63.7515(b), the EPA allows for less frequent performance testing if emissions are at or below 75 percent of the emission limit over three (3) consecutive years. However, 63.7550(c)(5) and 63.7555(d)(6) requires that annual reports and records, documenting that emissions in previous stack test(s) were less than 90 percent of the applicable emission limit, must be retained if a subject facility elects to test less frequently than annually. This appears to be a contradiction in setting the performance testing frequency threshold. Also, 63.7555(d) did not include paragraphs (d)(6) and (d)(7) in the citation for the section.

Response: EPA revised 63.7515(b) from 75 to 90 percent to be consistent with original intent. We also revised 63.7555(d) to include (d)(6) and (7).

Comment: Errors In Tune-Up Requirement Language

The proposed reference to conduct annual performance tune-ups in 63.7515(e) is in error. Sources complying with tune-up requirements are not required to conduct performance tests. In 63.7540(a)(11), boilers or process heaters with a heat input capacity of less than 10 million Btu per hour have a biennial tune-up instead of an annual requirement.

Response: EPA has revised 63.7515(e) within the final rule to account for biennial tune-ups for small units.

Comment: Small Boilers – Initial Compliance Requirements- § 63.7510(c)
The rule does not set emissions limits for units below 10 MMBtu, instead requires a work practice standard of tune-ups to be followed. § 63.7510(c) states "If your boiler or process heater has a heat input capacity less than 100 MMBtu per hour your initial compliance demonstration for CO is conducting a performance stack test for CO according to Table 5 to this subpart. " This could be interpreted that all boilers, including those below 10 MMBtu would require an initial stack test. This is in
conflict with the Preamble discussion regarding the technological and economical challenges of testing small diameter stacks. It is suggested that the language be clarified by changing this section to state "If your boiler or process heater is subject to an emissions limit your initial compliance demonstration for CO is conducting a performance stack test..." This is similar language to the proposed Area Source MACT Rule.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2775.1, Excerpt Number 23 to view the response.

Comment: Clearly State Emission Limits To Be Achieved

In 63.7522(a), the proposed rule states that facilities may demonstrate compliance if the averaged emissions are "within" 90 percent of the applicable emission limit. The word "within" should be replaced with "less than" and the "=" symbol in all of the equations in this section should be replaced with "<".

Response: EPA has revised 63.7522(a) within the final rule to replace "within" with "not more than" so there is a 10% credit to the environment. Changing the = sign in the equations is not needed because they calculate the actual weighted average emissions for the averaged units. This value needs to be less than the limit for the pollutant for the fuel type and unit type.

Comment: EPA Needs to Amend A Number of Rule Provisions to Reflect that Natural Gas Boilers and Process Heaters are Subject to Work Practices.

A number of the proposed initial compliance, monitoring, notification and recordkeeping requirements in the rule conflict with the requirements in § 63.7540 and Table 2 specifying that natural gas boilers and process heaters are subject to work practices and not emission limits. The following provisions need to be revised in the final rule to properly reflect the requirements for natural gas units:

(12) • Proposed § 63.7510, which addresses initial compliance requirements, is unclear in certain subsections with regard to whether the requirements only apply to units demonstrating compliance with emission limits. This provision should make it clear that the initial compliance demonstration requirements only apply where there is an emission limit applicable to a unit and that a unit subject to work practices is not required to demonstrate compliance. The wording in subsection (c) and (d), for example, is overly broad and could be interpreted to include units subject to work practice standards.

Response: EPA has revised 63.7510(a) through (d) within the final rule so they are not misinterpreted to include work practices.

Comment Excerpt Number: 61

Comment: Proposed 63.7515 Subsection (g) – This provision appears to require submittal of all fuel analyses within 60 days after completion of a performance test. This should be clarified to identify that stack testing and the corresponding fuel analysis be submitted within 60 days. Compliance with other fuel analysis requirements can be included in the deviation reporting in the existing Title V program.

Response: For the fuel analysis, we have revised the language to require reporting of the stack tests results and the initial fuel analysis done at the time of the stack test, which are used to set the maximum Cl and Hg contents. The other subsequent monthly fuel analyses are reported with the semi-annual compliance report.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group

Comment: In the proposed rule at 40 CFR 63.7525(a), EPA specifies that a CO CEMS must be installed on all boilers and process heaters that are more than 100 MM Btu/hr. This language would require that a CO CEMS be installed on all existing and new Gas 1-fired units. However, EPA did not establish CO limits for these units, so it should not be necessary to install a CO CEMS. We recommend that EPA eliminate this confusion by re-writing the first sentence of 63.7525(a) to read: "If your boiler or process heater has a CO limitation and has a heat input of 100 MMBtu per hour or greater…."

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2792.1, Excerpt Number 239 to view the response.
EPA has revised 63.7525(a) to clarify that only applies to units with CO limits.

Comment: In the proposed rule at 40 CFR 63.7525(b), EPA specifies that a PM CEMS must be installed on all coal, biomass and residual oil boilers and process heaters that are more than 250 MM Btu/hr. The Agency also requires at 40 CFR 63.7525(c), EPA specifies that a continuous opacity monitoring system (COMS) must be installed on all boilers and process heaters that are have an opacity requirement. Table 4 to Subpart DDDDD of Part 63 requires that 10% opacity must be met by any unit using a dry electrostatic precipitator (ESP). Requiring these two monitors on units >250 MMBtu/hr and using an ESP is redundant since they are indicators of emissions of the same pollutant, particulate matter, and it makes no sense to require both on the same unit. We recommend that this redundancy be eliminated by requiring only one continuous monitor.

Response: EPA revised the rule to only require a COPMS on units that are not already otherwise required to install a PM CEMS.

Commenter Name: Timothy Hunt
Commenter Affiliation: American Forest and Paper Association (AF&PA)

Comment: The phrase a major source of HAP as defined in 63.2 or 63.761 (40 CFR part 63, subpart HH, National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities) is unclear and should be revised. As proposed, this language would seem to say that a source which is major under either of the cited definitions is major for this rule. However, 63.761 is not an alternate to the 63.2 definition, as the proposed 63.7485 language indicates, but rather modifies it for certain oil and gas operations.

Recommendation: 63.7485 should be revised to read “a major source of HAP as defined in 63.2, except that for oil and gas facilities a major source of HAP as defined in 63.761 (40 CFR part 63, subpart HH, National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities),”

Comment Excerpt Number: 10

Comment: Proposed 40 C,F.R. § 63.7545(f) states that "If you operate a natural gas-fired boiler or process heater that is subject to this subpart... ." NEC questions whether a natural gas-fired boiler or process heater would be subject to this subpart, as the limits in Table 1 and 2 apply only to "other gases" which are defined as gaseous fuels other than natural gas,

Response: Natural gas fired units are part of the source category and affected source subject to this subpart but are not subject to any emission limits unless they fire other fuels that are subject to the emission limits. Please refer to the preamble for discussion of Gas 1 work practice standards.

Commenter Name: Matthew Todd and David Friedman

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 16

Comment: Under 63.7490(a)(2) another affected source is defined as each new or reconstructed industrial, commercial, or institutional boiler or process heater located at a major source as defined in 63.7575. In both the (a)(1) and (2) paragraphs the wording suggest that major source is defined in 63.7575, while it is actually the other terms in those paragraphs that are defined there. Major source is not defined in 63.7575.

Recommendation: Clarify 63.7490(a)(1) and (2) by moving the phrase "as defined in 63.7575" to a point earlier in the paragraph.

Response: EPA acknowledges the comment and has revised the final rule to avoid confusion with the definition of major source.

Commenter Name: Matthew Todd and David Friedman
Commenter Affiliation: American Petroleum Institute (API) and National Petrochemical and Refiners Association (NPRA)
Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 19

Comment: We also request that the language of the proposed exemptions in 63.7491(i) be clarified, to make it clear that the exemption applies to not only a boiler or process heater that is specifically listed as an affected facility under CAA sections 112 or 129, but also to any boiler or process heater that is part of an affected facility under those CAA sections. For instance, under part 63 subpart UUU, a CO boiler is part of the Fluid Catalytic Cracking Unit affected facility and its stack emissions (including CO) are regulated by that subpart, but CO boilers are not specifically listed as an affected facility on their own under that rule.

Recommendation: Clarify the exclusion for boilers and process heaters regulated by other HAP regulations, by deleting the word “specifically” from 63.7491(i).

Recommendation: Maintain the proposed exemption for temporary boilers and expand that exemption to cover boilers and process heaters that operate less than 30 days per calendar year or that operate at less than 30% of their design capacity as an annual average.

Response: EPA has revised the language within the final rule to exclude units that are part of the affected source subject to another subpart of this part (i.e., another NESHAP under 40 CFR part 63). EPA did not expand the exemption for low-use boilers and heaters.

Comment Excerpt Number: 35

Comment: Some typographical, grammatical and cross-reference errors were identified in the proposed rule.

§63.7490(a)(1) states "The affected source of this subpart is the collection of all existing industrial, commercial, and institutional boilers and process heaters within a subcategory located at a major source as defined in §63.75 75.- This phrasing could lead to confusion since the term "major source" is not defined in §63.7575. Moving the phrase "located at a major source" could resolve the potential confusion and make it clear that the reference is to the subcategory definitions: "The affected source of this subpart is the collection of all existing industrial, commercial, and institutional boilers and process heaters located at a major source within a subcategory located at a major source as defined in §63.7575."

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2960.1, Excerpt Number 16 to view the response.

Comment Excerpt Number: 72

Comment: Requirements associated with the timing of the tune-up requirements are contained in 63.2515(e) as discussed below. This section is titled When must I conduct subsequent performance tests or fuel analyses? Along with the wording of paragraph (e), placing this information in this section suggests the tune-up is a performance test and thus subject to the notice and other requirements associated with performance tests. Making the tune-up work practice into a performance test is unreasonable, since there is no specific standard that the tune-up must attain. Furthermore, adding all the costs and burdens associated with a performance test was not included in the evaluations of this work practice or in the Information Collection Request. This information should be moved to another section of the rule or language added to make clear the tune-up is not a performance test.

Recommendation: Move the timing requirements for tune-ups out of the performance test section and make clear that tune-ups are not performance tests.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2525.1, Excerpt Number 18 to view the response.

Comment Excerpt Number: 74

Comment: Proposed 63.7540(a)(10) contains the specific tune-up work practice requirements for existing boilers and process heaters.

The proposed 63.7540(a)(10)(i)-(iii) reflect typical tune-up activities. Many jurisdictions require annual boiler inspections for safety reasons and boilers are often spared or can be shutdown when weather conditions are mild. Some jurisdictions require such inspections for process heaters particularly as part of a NOx minimization effort. However, not all boilers and few process heaters can be readily shut down. The proposed (a)(10)(i) and (ii) burner inspections could require such a shutdown, since burners are not always retractable and cannot always be inspected or cleaned with the process heater in service. In those cases where the boiler or process heater is not spared or cannot be shutdown without impacting steam or process heat consumers, this requirement should allow for delaying the burner inspection until the unit can be shut down without impact. Potential unit and process shutdowns were not considered in evaluating the tune-up emissions impacts, costs or burdens and are not justified.

Recommendation: Clarify that boiler and process heaters need not shut down to accomplish the required inspections or to clean burners.

Response: EPA acknowledges the comment but did not complete the recommended change because it would basically allow a source to not do the tune up indenfinitely.

Comment: Proposed 63.7515(e) starts out If you are required to meet an applicable work practice standard, you must conduct annual performance tune-ups... However, in addition to the tune-up work practice, there is an energy audit work practice, that will likely apply to all facilities. Thus, 63.7515(e) can be interpreted to override the biennial tune-up requirement for units <10 MMBTU/hr.

Recommendation: Revise the first sentence of 63.7515(e) to "If you are required to meet an applicablethe tune-up work practice standard, you must conduct annual performance tune-ups...

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2525.1, Excerpt Number 18 to view the response.

Comment: Additionally, § 63.7540(a) does not appear to recognize the provisions set forth in § 63.7510 that exempt units that fire a single fuel from conducting fuel analyses during performance stack testing. Additional provisions should be included in this section to recognize the exemption from fuel analysis testing during performance stack testing in § 63.7510 for units that fire a single type of fuel.

Clarification of Equation 7.

EPA requires that during performance testing for HCl, sources must determine "the fraction of the total heat input for each fuel type burned (Qi) based on the fuel mixture that has the highest content of chlorine, and the average chlorine concentration of each fuel type burned (Ci)." 75 FR 32057. The "maximum chlorine input level" must be determined using "Equation 7". 75 FR 32057. The definition given for Qi is unclear. EPA should clarify Equation 7 and the explanation given for Qi (i.e. "the fraction of total heat input from fuel type."). 75 FR 32057.

Response: EPA has added language to 63.7530(b) for clarification. If you switch fuels, you need to determine if you are increasing the Cl input. If it has increased, a performance stack test must be completed to determine compliance. Equation 7 was not revised because units that burn only a single fuel may do an analysis to show that they have not increased the Cl or Hg input and do not need to do a new stack test.

Comment: Monitoring
EPA Should Clarify CO CEMS are not Required for Gas 1 boilers >100 MMBtu/hr.
EPA should re-draft the proposed § 63.7525(a) so that it is applicable only if a unit has a CO limitation and a heat input of 100 MMBtu/hr or greater. Such clarification will ensure that unnecessary and costly requirements are not imposed on the Gas 1 subcategory or on Gas 2 units if numerical limits are not established.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2792.1, Excerpt Number 239 to view the response.

Document Control Number: EPA-HQ-OAR-2002-0058-2960.1
Comment Excerpt Number: 164

Comment: Proposed 63.7510(c) requires CO performance testing boilers and process heaters with a heat input capacity of <100 MMBTU/hr even if no CO emission limit applies to that boiler or process heater. Without an applicable emission limit, there is no reason to performance test and testing such units certainly was not considered in the supporting record for this rulemaking.

63.7510(c) also requires a CO performance evaluation for the CO CEMS required by 63.7525(a) for all boilers and process heaters of ?100 MMBTU/hr, whether or not a CO emission limit applies. This requirement also must be changed to only apply to boilers and process heaters subject to a CO emission limit.

Recommendation: Revise 63.7510(c) to only apply to boilers and process heaters where a CO emission limit applies.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2775.1, Excerpt Number 23 to view the response.

Comment Excerpt Number: 236

Comment: Proposed 63.7550(g) requires certain certifications. These requirements need clarification as follows. Also, note the (g) paragraphs should be numbered (1), (2) and (3), not (i), (ii) and (iii).

Proposed 63.7550(g)(i) requires a certification that This facility complies with the requirements in 63.7540(a)(10) to conduct an annual tune-up of the unit. However, most major sources will have many units subject to the tune-up requirement and this statement needs to be in the plural.

Proposed 63.7550(g)(ii) requires a certification that This facility has had an energy assessment performed according to 63.7530(e). However, the energy audit is a onetime requirement and, if it is finalized, this certification should be in the NCS and not have to be repeated in every compliance report.

Response: EPA moved the referenced paragraph and the three subparagraph to 63.7545(e)(8). 63.7550(g) was reserved.

Commenter Name: Robert P. Strieter
Commenter Affiliation: The Aluminum Association
Document Control Number: EPA-HQ-OAR-2002-0058-2711.1
Comment Excerpt Number: 6

Comment: The proposed rule requires the owner/operator to conduct a one-time Energy Assessment as a “beyond the MACT floor” control requirement. As described in the preamble and defined in the proposal rule, the scope of the Energy Assessment appears to go beyond the specific emission units regulated under the Boiler MACT by including the entire “major source facility” under this Energy Assessment. If this was EPA’s intent, the Aluminum Association opposes a requirement to conduct an energy assessment on facility operations which are not subject to the Boiler MACT rule. EPA needs to clarify that the Energy Assessment need only include the affect source(s) under Subpart DDDDD, which are the boilers and process heaters located at the facility.

Response: Please refer to the preamble for discussion of EPA's authority to require energy audit and energy audit requirement changes and discussion of the alternate output based standards and emission credits.

Comment: The rule also proposes an approach for compliance requirements for various boiler and emission control technology configurations (75 FR 32014). Specifically, Section III.G.(4) states "For boilers and process heaters with dry scrubbers, we are proposing that you continuously monitor the sorbent injection rate and maintain the sorbent injection rate and maintain it at or above the operating limits established during the performance tests." Given there is no analogous section regarding dry injection systems, we presume this section was intended to cover these systems as well. Accordingly, we suggest this be clarified by adding "or dry injection systems" after "dry scrubbers" in this section.

Response: EPA added requirements for dry injection systems.

Comment: Within the proposed rule, IV. Summary of This Proposed Rule, D. What are the proposed MACT and GACT standards, the following statement is made,"If your boiler bums oil, or oil in combination with a gaseous fuel, the unit is in the oil subcategory, except if the unit burns oil only during periods of gas curtailment."

Gas curtailment needs to be clearly defined in the rule, and in CSU's current tariff with our interstate transport supplier, we reference curtailment pursuant to the Natural Gas Policy Act of 1978.

Response: EPA acknowledges the comment and has updated the final rule to correct typos and reference errors. We have adjusted the definition of curtailment in the final rule. This standard does not employ GACT standards, which are covered under the area source rule.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 9

Comment: 40 CFR 63.7505 is entitled "What are my general requirements for complying with this subpart?" 40 CFR 63.7505(c) begins with compliance demonstrations for HCl or mercury. The last sentence in that paragraph states that "You must demonstrate compliance with all other applicable limits using performance stack testing, or the continuous monitoring system (CMS) where applicable." It is likely that this sentence is intended as a general statement covering all of the compliance demonstration options, but as written, it is more confusing than helpful, for the following reasons:

This sentence could be easily missed by someone not interested in HCl or mercury compliance demonstration methods and therefore should either be a separate paragraph or be used at the beginning of the sentence with HCl or mercury compliance listed as an exception to the more general requirement.

The sentence is confusing because it could be interpreted that there is an option between performance stack testing or CMS. This is inconsistent with 40 CFR 63.7530(a) which states that “you must demonstrate initial compliance with each emission limit that applies to you by conducting initial performance tests (performance stack tests and fuel analyses) and establishing operating limits...,” i.e. there is no mention in the latter that demonstrating compliance with emission limits by CMS is permissible, but rather that operating limits will be established.

It appears that compliance maybe demonstrated by CEMS (PM or CO1), but not by parametric monitoring. The Division suggests that the use of the general term "CMS" be avoided when only the specific (CEMS) is allowed. Although doubtful this is the intent, if parametric monitoring is permitted without stack testing to establish correlations between operational parameters and compliance with emission limitations, the Division disagrees that it should be allowed and therefore the regulation should be very clear that is not the case. Furthermore, use of parametric monitoring is useful as a substitute for direct monitoring of emissions for continuous monitoring purposes, but is not adequate for compliance demonstrations with emission limits.

[Footnote 1: See 40 CFR 63.7510(c) and (d). Note that these paragraphs are not consistent with 40 CFR 63.753(a).]

Response: We have revised 63.7505(c) and (d). We changed the order in (c) so that the first sentence refers to CEMS and COMS. We revised (d) to clarify that a CPMS is only used to comply with an operating limit after a performance stack test.

Comment: 40 CFR 63.7530, which is entitled, “How do I demonstrate initial compliance with the emission limits and work practice standards.” Also is related to initial compliance. It appears that 40 CFR 63.7510 is intended to cover initial compliance after the regulation is newly promulgated while 40 CFR 63.7530 is intended to cover initial compliance thereafter. However, the two are inconsistent and it is not clear why. For example, as noted above, 40 CFR 63.7530 does not appear to permit compliance demonstration by CEMS and COMS, whereas 40 CFR 63.7510(c) and (d) do permit initial compliance by CO and PM CEMS. The Division suggests that these two sections be merged to ensure consistency, and where divergence is intended, it would be clearer if the different requirement was explicitly identified as such.

Response: We revised 63.7530(a) to add: "If applicable, you must also install, and operate, maintain all applicable CMS (including CEMS, COMS, and continuous parameter monitoring systems) according to §63.7525. Although there is some overlap in these two sections, the revised language does add clarity to this concern.

Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 76

Comment: Proposed § 63.7530(b) contains incorrect references for all the proposed requirements. Specifically, it states that units demonstrating compliance through performance stack testing must "establish each site-specific operating limit in Table 2 . . . that applies . . . according to the requirements in § 63.7520, Table 7 . . ., and paragraph (c)(4) or this section." 75 Fed. Reg. at 32,056. However, proposed Table 2 sets out emission limits for existing boilers and process heaters, not "site-specific operating limits." Operating limits are in proposed Table 4. Paragraph (c)(4) addresses Hg emission rates from fuel analysis. Paragraph (b)(3) addresses parameter operating. Proposed § 63.7530(b) also states that all such units must conduct fuel analysis and "establish maximum fuel pollutant input levels according to paragraphs (c)(1) through (3). . ." 75 Fed. Reg. at 32,057. Paragraphs (c)(1) through (3) address units that demonstrate compliance through fuel analysis, not through performance testing. Paragraphs (b)(1) through (3) appear to be the procedures for establishing maximum fuel pollutant input levels.

Response: EPA has updated the final review to correct reference errors and the references in 63.7530(b) have been corrected.

Commenter Name: Deb Hastings
Commenter Affiliation: Texas Oil and Gas Association
Document Control Number: EPA-HQ-OAR-2002-0058-2857.1
Comment Excerpt Number: 2

Comment: §63.7485 should be revised to read "a major source of hazardous air pollutants (HAP) as defined in §63.2, except that for oil and gas facilities a major source of HAP as defined in §63.761 (40 CFR part 63, subpart 1111, National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities)"

Per proposed §63.7485, this regulation applies to an "industrial, commercial, or institutional boiler or process heater as defined in §63.7575 that is located at, or is part of, a major source of HAP as defined in §63.2 or §63.761 (40 CFR part 63, subpart IfEl, National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities), except as specified in §63.7491." This phrase is unclear and should be revised. As proposed by the U.S. Environmental Protection Agency (EPA), this language would seem to say that a source which is major under either of the cited defmitions is major for this rule. However, §63.761 is not an alternate to the §63.2 definition, as the proposed §63.7485 language indicates, but rather modifies it for certain oil and gas operations.

Response: EPA acknowledges the comment and has revised the section within the final rule to avoid the ambiguity.

Commenter Name: Jim Eubank

Comment Excerpt Number: 10

Comment: 40 CFR 63.7505(c) and (d) do not belong under general requirements, but rather should be listed under sections relating to emission and operating limit compliance demonstrations, of which there are at least two: 40 CFR 63.7510 which is entitled “What are my initial compliance requirements and by what date must I conduct them” and 40 CFR 63.7530 which is entitled “How do I demonstrate initial compliance with the emission limits and work practice standards.”

Response: EPA acknowledges the comment but no change was made. It is not clear that this text should be moved to the later rule sections. 63.7505(c) and (d) are still general in nature.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 11

Comment: Because 40 CFR 63.7505(d)(1) (rules for site-specific monitoring) is listed as subordinate to 40 CFR 63.7505(d) (requirement to develop site-specific monitoring if compliance is demonstrated via performance stack testing), it could be interpreted to mean that 40 CFR 63.7505(d)(1) only applies if 40 CFR 63.7505(d) applies. However, it appears that 40 CFR 63.7505(d)(1) should apply to all CMS, or at least, all parametric monitoring, since much, if not all, the requirements are duplicative of regulations governing CEMS and COMS. The Division suggests that 40 CFR 63.7505(d)(1)-(4) be moved to sections pertaining to monitoring, such as 40 CFR 63.7535 or 40 CFR 63.7540, or at least elevated so that it is not subordinate to 40 CFR 63.7505(d) (i.e., 40 CFR 63.7505(e)).

Response: We modified section 63.7505(d) to encompass all types of CMS (CEMS, COMS, and CPMS) to clarify the applicability requirements of (d)(1) through (d)(4).

Comment: Recommend that EPA remove the requirement at section 63.7525(i)(j)(6) that the BLD should activate an audible alarm.

The referenced section states:

(6) The bag leak detection system must be equipped with an alarm system that will sound automatically when an increase in relative particulate matter emissions over a preset level is detected. The alarm must be located where it is easily heard by plant operating personnel.

Many boiler control rooms are equipped with visual alarms that the operator must acknowledge and respond to. The type of alarm that is used must be at the discretion of the plant, may be affected by safety or plant operational priorities, and should not be specified by EPA.

Response: EPA has revised 63.7525(i)(j)(6) to allow either audible or visual alarms.

Comment: § 63.7540(a) does not appear to recognize the provisions set forth in § 63.7510 that exempt units that fire a single fuel from conducting fuel analyses during performance stack testing. Additional provisions should be included in this section to recognize the exemption in § 63.7510 for units that fire a single type of fuel from fuel analysis testing during performance stack testing.

Response: EPA has added language to 63.7530(b) for clarification. If you switch fuels, you need to determine if you are increasing the Cl input. If it has increased, a performance stack test must be completed to determine compliance. Equation 7 was not revised because units that burn only a single fuel may do an analysis to show that they have not increased the Cl or Hg input and do not need to do a new stack test.

Commenter Name: Jim Eubank
Commenter Affiliation: Kentucky Division of Air Quality
Document Control Number: EPA-HQ-OAR-2002-0058-3176.2
Comment Excerpt Number: 18

Comment: 40 CFR 63.7515 is entitled "When must I conduct subsequent performance tests or fuel analyses." As the title suggests, this section pertains to when tests are performed, as opposed to what subsequent compliance demonstrations are required. Other sections related to compliance demonstrations specify "initial". The Division recommends that the regulation explicitly state what subsequent compliance demonstrations are required. In the alternative, no distinction should be made between initial and subsequent compliance determinations generally and where distinctions are made, they be explicitly identified.

Response: EPA has revised the langage slightly in different parts of the rule to clarify whether a procedure was for the initial or all compliance demonstrations. However, the rule is already reasonably clear on what needs to be done and when to do it.

Comment: EPA should correct the following errors in the proposed rule:

The operating limits for parameter monitoring systems (scrubber effluent pH, liquid flow rate, pressure drop, etc.) should be based on the 4-hour run performance test required by section 63.7520(d). Specifically, section 63.7525(d)(4) should be modified from “determined the 3-hour block average” to “determined the 4- hour block average”. This is also specified in the preamble (75 FR 32033, 3rd paragraph) which states,” ...You would be required to set parameters based on 4-hour block averages during the compliance test, and demonstrate continuous compliance by monitoring 12-hour block average values for most parameters. We selected this averaging period to reflect operating conditions during the performance test to ensure the control system is continuously operating at the same or better level as during a performance test demonstrating compliance with the emission limits”.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-2777.1, Excerpt Number 44 to view the response.
EPA has revised 3-hour averages to 4-hour averages within the final rule.

Commenter Affiliation: Utility Air Regulatory Group
Document Control Number: EPA-HQ-OAR-2002-0058-2880.1
Comment Excerpt Number: 77

Comment: Although UARG does not believe PM CEMS should (or can) be required for compliance determinations under this rule, UARG notes that EPA's proposed rule, which does provide for use of a PM CEMS, does not exempt those units from the other performance testing and operating limit requirements in proposed § 63.7530 and § 63.7515. In fact, in the preamble, EPA states that compliance with PM standards is always determined by "initial and annual stack tests . . . using EPA Method 5 or 17." 75 Fed. Reg. 32,013. This statement is inconsistent with the proposed 63.7510(d).

Response: EPA has revised 63.7510(d) within the final rule to add a sentence saying that boilers and process heaters that use a CEMS for PM are exempt from the performance testing and operating limit requirements specified in paragraph (a) of that section (63.7510).

Comment Excerpt Number: 239

Comment: In the proposed section 63.7525(a), EPA specifies that a CO CEMS must be installed on all boilers and process heaters that are more than 100 MM Btu/hr. This language would require that a CO CEMS be installed on all existing and new Gas 1-fired units. However, EPA did not establish CO limits for these units, so it should not be necessary to install a CO CEMS.

We recommend that EPA eliminate this confusion by re-writing the first sentence of 63.7525(a) to read: "If your boiler or process heater has a CO limitation and has a heat input of 100 MMBtu per hour or greater...."

Response: EPA has revised 63.7525(a) within the final rule to clarify that only applies to units with CO limits

Comment: Section 63.7530 (b) should reference Table 4 for establishing operating limits instead of Table 2, which contains emission limits.

Response: EPA has updated the final rule to correct reference errors and has correct the Table 4 reference.

Commenter Name: Jim Griffin
Commenter Affiliation: American Chemistry Council
Document Control Number: EPA-HQ-OAR-2002-0058-2792.1
Comment Excerpt Number: 243

Comment: At section 63.7530(b)(3), the reference should be (b)(3)(i) through (iv), not (c)(4)(i) thru (iv).

Section 63.7530(b)(3)(ii) seems to require setting secondary voltage and current operating ranges for all ESP's, whether or not they are followed by additional wet control. This language is in conflict with Table 4 (Item 3) and Table 7 (Item 1.b). EPA should clarify the language in section 63.7530(b)(3)(ii) to indicate that ESP parameter operating ranges should only be set if the ESP is followed by a wet control device.

Response: This comment has previously been addressed. Please refer to comment EPA-HQ-2002-0058-3213.1, Excerpt Number 318 to view the response.
EPA has revised the section to clarify the applicability.

Comment Excerpt Number: 8

Comment: Although the format of the proposed rule may technically be adequate, the proposed rule is difficult to read and interpret. Many sources that will be subject to this rule are not large entities with specialized environmental staff. Therefore, we strongly recommend that EPA write the rule in a more readable format to enable the regulated community to better understand and meet the requirements. Simply providing implementation tools such as fact sheets and memos will not meet the need for a clear, concise and readable rule.

Response: We have modified and corrected several reference errors in response to public comments and modified regulatory strategies. EPA will conduct training sessions on this rule and be available to answer technical rule implementation questions.

Comment: The MACT Rules are all but unreadable
Owners, managers and operators of biomass-fired boilers are very busy people. The length, format and the rambling question-and-answer nature of the MACT "rule" are not acceptable.

In preparing the final rule, kindly provide summary documents that are clear , concise, and to the point. If you must include an additional 200 to 300 pages for the lawyers to decipher, then so be it.

Response: We have modified and corrected several reference errors in response to public comments and modified regulatory strategies and streamlined requirements, when appropriate. EPA will continue to develop trainings on this rule to inform the regulated community.

Startup, Shutdown, and Malfunction (SSM)

SSM Regulatory Text Provisions

Comment: At refineries and chemical plants it is well established from state emissions data that there have been decades of routine violations of emission standards during so-called malfunction events.

When these events happen, the neighboring communities are blanketed in toxic emissions. People are made sick immediately. They lose work days. They have to visit doctors and seek medical care that many can't afford. Their children miss school. And because the emissions are so toxic it also increases their chances of catastrophic health effects like cancer and birth defects.

Now, this exemption has been ruled unlawful by a Federal Court of Appeals. We hope that EPA will be taking it out of other rules but taking it out of this rule which governs thousands of major sources of hazardous air pollutants, including many of the worst abusers of the exemption, will go a long way by making them run their sources cleanly or be held accountable; and we think this is very important.

Response: See preamble for response to changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA's promise to address periods of equipment malfunction by considering other information before enforcing exceedance of operating limits also provides little comfort, especially given the risk of citizen suits. Although NREGA appreciates EPA's proposal to make clear that "deviations" of operating limits are not necessarily violations, nothing in EPA's proposal would prevent EPA, a state, or a plaintiff in a citizen suit from simply determining in their "discretion" that any particular exceedance constitutes a violation. MACT standards are technology-based standards, and NREGA believes the agency must recognize that even the best performing technology occasionally fails.

Comment: It should be clarified that EPA established only one-of-the-five pollutants' standards (CO) with emission data collected during startup and shutdown periods. EPA can mislead readers to infer that all standards were based with startup and shutdown data by stating on pp. 32012-13 that "Din establishing the standards in this rule, EPA has taken into account startup and shutdown periods..." EPA should clarify that PM, HCI, Hg, and dioxins emission data were not collected during startups and shutdowns, but rather during typical, steady-state (if not best) conditions.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: The NC DAQ has developed SSM provisions for related plan requirements, recordkeeping, and reporting that have been accepted by and are working for some of our Title V permitted facilities. Such provisions are worthy of EPA consideration and include:

NC agrees that emission data from malfunctions should not be included in evaluation against the standards because it would be impracticable and problematic, given that malfunctions can vary in frequency, degree, and duration, further complicating standard setting.

Malfunction emission counting notwithstanding, some form of constraint and accountability needs to be placed on malfunctions through integrated documentation with the facility standard operating procedures (SOPs) and/or maintenance manuals.

To be considered a malfunction, the breakdown must be unforeseeable and un preventable. A foreseeable and preventable breakdown is not regarded as a malfunction, but rather a failure of good operation and maintenance using best practices, triggering a notice of violation and possibly an enforcement fine.

Facility CEM data are reviewed to determine the percentage of time specific emission control equipment is in startup, shutdown, malfunction, and other excess emission periods. NC DAQ has established a Continuous Monitoring Enforcement Plan (CEP) which sets maximum excess emission period levels not to be exceeded. These maximum levels include excess emission periods during startup, shutdown, malfunction, known events, and unknown events. Periods of excess emissions during 3- or s-mornh periods are allowed up to their respective time limits, as long as the explanations of the excess emissions events meet the definitions of startup, shutdown, and malfunction. When any 3- or 6-month excess emission level is exceeded, the facility is deemed in non-compliance with 40 CFR 63.94 and NC rules. Although NC DAQ evaluates excess emissions on a broader range (i.e., we also count known and unknown event periods), we recommend EPA stay with the strict definition of SSM when applying this concept by not including known and unknown excess emissions in the calculation.

NC has a longstanding regulation for evaluating and exempting malfunctions for non·MACT sources. North Carolina Administrative Code 2D.0535 requires NC DAQ to consider at least the same elements that EPA has stated on page 32013 of the proposed rule for malfunction evaluation. In order for the agency to review a malfunction, the facility must meet the following requirements:

The owner or operator of a source of excess emissions that last for more than four hours and results from a malfunction, a breakdown of process or control equipment or any other abnormal conditions, shall:

(1) Notify the permitting agency of any such occurrence by 9:00 am of the agency's next business day of becoming aware of the occurrence and describe:

(A) Name and location of the facility,

(B) The nature and cause of the malfunction or breakdown,

(C) The time when the malfunction or breakdown is first observed. (D) The expected duration, and

(E) An estimated rate of emissions;

(2) Notify the permitting agency immediately when the corrective measures have been accomplished;

(3) Submit to the permitting agency Within 15 days atter the request a written report that includes:

(A) Name and location of the facility,

(B) Identification or description of the processes and control devices involved in the malfunction or breakdown,

(C) The cause and nature of the event,

(D) Time and duration of the violation or the expected duration of the excess emission if the malfunction or breakdown has not been fixed,

(E) Estimated quantity of pollutant emitted,

The owner or operator of a source of excess emissions that last for more than four hours and results from a malfunction, a breakdown of process or control equipment or any other abnormal conditions, shall:

(1) Notify the permitting agency of any such occurrence by 9:00 am of the agency's next business day of becoming aware of the occurrence and describe:

(A) Name and location of the facility,

(B) The nature and cause of the malfunction or breakdown,

(C) The time when the malfunction or breakdown is first observed. (D) The expected duration, and

(E) An estimated rate of emissions;

(2) Notify the permitting agency immediately when the corrective measures have been accomplished;

(3) Submit to the permitting agency Within 15 days atter the request a written report that includes:

(A) Name and location of the facility,

(B) Identification or description of the processes and control devices involved in the malfunction or breakdown,

(C) The cause and nature of the event,

(D) Time and duration of the violation or the expected duration of the excess emission if the malfunction or breakdown has not been fixed,

(E) Estimated quantity of pollutant emitted, fixed, steps planned to be taken, and

(G) Any other pertinent information requested by the permitting authority.

Normally most of the malfunction report elements come with initial contact by the next business morning. NC facilities frequently contact OAQ for assistance early in an incident. Prompt response by the agency can often help shorten or reduce the period of excess emissions.

A similar set of requirements for malfunction reporting can be included in the Boiler MACT. For malfunctions to be evaluated quickly and effectively, burden for implementation would have to fall on the permitting agency. Whether a request threshold of two, three or four hours should be included in the language is discretionary. Such a threshold could prevent excessive burden on permitting agencies for evaluations and still provide facilities some relief for more serious and complicated incidents. The final written report could follow 5 or less days following the end of the malfunction.

Comment Excerpt Number: 17

Comment: EPA has a responsibility to set and enforce limits that a source can meet (i.e., achievable), not create a limit that is unattainable by any source in the US, new or existing. The proposed approach is the equivalent to setting the speed limit at an oncoming ramp to an interstate at 5 mph, and then expecting the car to immediately reach the speed of interstate traffic (55 mph or more) with no adverse events. The expectation of a source to comply immediately upon startup, which is known to have higher CO emissions,[While GPI does not have a CO CEM on the existing biomass boiler to support this statement, the Recovery Furnace CO CEM does she a pattern of higher CO emissions during startup procedures. This stems in part from the use of fossil fuel in the boiler during startup and the need to bring the furnace up to the typical combustion temperature. A similar trend would be expected in a woody biomass boiler.] without taking into account these emissions when setting the MACT floor, is no different. While EPA states that startup and shutdown data have been used to establish the standards, this statement is false for biomass stokers and biomass fluidized bed boilers. GPI — Macon Mill urges EPA to reconsider emissions during startup and shutdown. Accordingly, GPI — Macon Mill contends that EPA needs to establish separate emission limitation or, preferably, work practice standards specific to startup and shutdown operations.

Comment: Aside from this legal deficiency, EPA's proposed floor setting methodology fails to adequately consider emissions variability that occurs during SSM periods. In its proposal EPA asserts that "[t]he standards we are proposing are daily or monthly averages ... [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." (75 FR 32013). However, EPA uses short term performance test results rather than the results of long-term CEMS monitoring to set the floors, the only exception for biomass boilers being CO CEMS analysis on only two units. As a result, the emissions data on which the floors are based do not, in fact, reflect or adequately accommodate emissions during SSM periods. Furthermore, EPA's daily average only applies to CEM pollutants. Most emissions (HCl, mercury, dioxin/furan) are tested using EPA Reference Methods which determine emissions over a three to twelve hour average. Neither EPA's emission limits nor compliance averaging times adequately accommodate variability in emissions due to SSM.

Emissions can be significantly higher during SSM due to the unavoidable less-thanoptimal emissions control performance during transitional (non-steady state) conditions. For example, at biomass-to-energy facilities combustion-related emissions such as CO, particulate (smoke) and opacity increase during the startup period when load and temperature are coming up to full load steady-state conditions. The Maine Department of Environmental Protection has stated "Wood and multi-fueled boilers produce large CO variations during startups as the boiler heats up. Start-ups can take up to 14 hours for some units. Shutdowns can also result in significant CO variability."[Letter James P. Brooks, Bureau Director, State of Maine Bureau of Air Quality to James Eddinger, USEPA, February 4, 2010.]

(See submittal for ME DEP report] Startup burners reduce emissions by preheating the combustion chamber and downstream equipment but are not sized to achieve full load temperatures and even if they were could not completely avoid temporary sub-optimal combustion conditions as heat load shifts from auxiliary fuel to waste during startup and from waste to auxiliary fuel during shutdown. Air pollution control equipment goes through similar transient temperature and flow conditions. These conditions are distinct from the variable conditions that occur during normal operation. EPA's emission database excludes SSM periods and therefore does not capture this component of variability, leading to MACT floors that have not been achieved in practice. [See submittal for example CO concentrations during startup and shutdown.]

EPA should set standards which incorporate SSM emissions. There are a few options. First, EPA could set standards applicable at all times which reflect the emissions variability inclusive of SSM. Second, EPA could set distinct standards which would apply only during SSM periods. Both these options are problematic - since its emission database does not contain SSM data EPA would need to gather additional test data for the various categories and units. EPA could use certified continuous emissions monitoring data for those few pollutants that are continuously monitored, but non-CEM pollutant data would likely be unavailable and involve a costly and time-consuming effort to collect using manual methods. Collecting non-CEM pollutant data is further complicated by the fact that EPA's stack testing procedures (40 CFR 60, Appendix A) require that testing be conducted under steady state conditions.

Comment Excerpt Number: 17

Comment: If Start-up, Shut-down and Malfunctions are considered to be part of normal operations during which compliance must be maintained, then it is only logical that some of the data evaluated to determine the MACT floor must incorporate these time periods somehow. Obviously malfunctions are unpredictable as stated in the preamble and cannot be tested. Furthermore various malfunctions will likely have different effects on the emissions making evaluation even more difficult. However, start-ups can be predicted and could be evaluated. It is recommended that the top performing boilers be retested or monitored with the appropriate CEM to determine the effect a start-up and shut-down has on the emissions and how the limits should be adjusted. To set the limits without even knowing the effect of these events and expect compliance during them may be setting up every source for failure. At this point we simply do not know the outcome.

Comment: Compliance with the proposed CO limits is problematic particularly during unit startups. As discussed in section I.H. above, there is no factual support for EPA's conclusion that the CO standard is "achievable" during plant startup. No CO emissions testing was conducted during plant startup of biomass units. Startup of a biomass can take up to a day. During startup, work practice standards are more appropriate than CO emission limits.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-3179
Comment Excerpt Number: 18

Comment: Sampling methods used to gather data for forming the MACT floors must be standardized so that the dataset integrity is maintained and consistent with reporting methods. Since there are no proposed SSM exceptions, data must reflect the inclusion of start-ups and shutdowns to be relevant. Sampling done during steady state operating conditions will not reflect variable conditions that are present during start-up/shutdown periods. DGC requests a more extensive sampling effort to expand the dataset used to determine the MACT floors.

Comment Excerpt Number: 18

Comment: GPI — Macon Mill contends that EPA should establish work practice requirements to address malfunction events. In the reality of manufacturing operations, malfunctions do occur. Per 40 CFR 60.2, EPA has defined malfunctions as sudden, infrequent and not reasonably preventable failure of air pollution control and monitoring equipment, process equipment or a process to operate in a normal or usual manner.... As EPA has already noted, per this defmition, malfunctions are "not reasonably preventable" and are clearly distinct from normal, startup, or shutdown operations; it does not make sense that EPA then concludes, on page 32013 of the Federal Register, that malfunctions should not be viewed as a distinct operating mode and, therefore, any emissions that occur at such times do not need to be factored into development of the CAA Section 112(d) standards, which, once promulgated, apply at all times. Even the "best perfolining- sources will encounter malfunction events — it is a practical reality. GPI — Macon Mill encourages EPA to consider a work practice standard similar to the prior requirement for a plan to operate in a manner that minimizes the emissions of pollutants during a malfunction event.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-2918.1
Comment Excerpt Number: 18

Comment: EPA makes a similar mistake with regard to its proposal not to set a separate standard for periods of startup, shutdown, and malfunction. On the one hand, EPA asserts that "[t]he standards we are proposing are daily or monthly averages ... [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." On the other hand, EPA uses short term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction.

EPA must use data to set the standard that are consistent with the form of the standard. As compliance with the CO standard is to be measured at all times using CO CEMS for units of 100 MMBtu/hr and greater and the averaging time is 30 days, EPA should use 30-day CEMS data from affected boilers to establish the appropriate MACT floors and not 3-run stack test data.

To assure that startup, shutdown, and malfunction are appropriately accommodated, EPA must either assure that the data on which the standard is based include representative data from such periods or, alternatively, set a separate work practice standard to properly accommodate startup, shutdown, and malfunction.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: There are also difficulties trying to set concentration-based standards corrected to a standard diluent concentration (e.g., ppmdv @ 3% O2) for startup and shutdown periods. Emission concentrations soar artificially due to the exponentially increasing correction factor as the stack oxygen concentration approaches ambient levels and CO_2 concentrations approach zero. At low unit loads at the beginning of startup or at the end of shutdown corrected emission concentrations could be very high giving the appearance of significant emissions when the actual mass emissions (pounds per hour) are small due to the lower stack volumetric flow rates. If EPA decides to set concentration standards for SSM periods it should recognize the diluents caps of 14 percent for oxygen or 5 percent for carbon dioxide in emission calculations as is currently done in the Large MWC MACT rule (40 CFR 60.58b (b)(8)).

ERC supports a third option for a boiler MACT SSM standard which solves both the data availability and concentration-based standards problems. This approach would require that each State address SSM emission standards in its State Implementation Plans (SIP). The SIP would specify a procedure which would be used to set mass emission standards (e.g., pounds per startup period) for each subcategory and unit case-by-case based on emissions reductions achieved using accepted startup, shutdown and malfunction related procedures. For example, for a unit using an auxiliary burner for startup the CO standard (pounds per startup) would be set considering the limitations of the properly operated burner and boiler design during a defined startup period. SSM emissions would be minimized by the same emission reduction technologies that would enable units to comply with all Major Boiler MACT standards and would thus represent a small component of a unit's annual emissions. The case-by-case SSM emission limits would be written into facility permits and become federally enforceable mass emission standards. The unit's continuous emission monitoring system (CEMS) would be used to calculate and report mass emissions during SSM periods.

Document Control Number: EPA-HQ-OAR-2002-0058-2912
Comment Excerpt Number: 18

Comment: According to §63.7505, the requirements of the proposed rule apply at all times. However, it is clear that no startup and shutdown emission data was included in the database used to generate the proposed emission limits and that boilers and process heaters cannot meet all of the proposed emission limitations during all periods of startup and shutdown. In fact, it is forbidden by §63.7(e) of the Part 63 General Provisions for performance tests to include startup, shutdown or malfunction periods in performance tests. Even units that can be retrofitted with controls that allow achieving the emission limits during normal operations will be unable to meet the limits during some startups and shutdowns, because many of the controls are not effective at the low stack temperatures that occur during startup and shutdown periods.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Gordon M. Smith
Commenter Affiliation: Mitsubishi Polyester Film, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-2912
Comment Excerpt Number: 20

Comment: The issue of the impacts of startups and shutdowns on emissions of other pollutants are not discussed. Emissions result from pollutants contained in fuel (i.e., Hg and Cl-) are unlikely to be different during startup and shutdown periods, but a simple understanding of combustions suggest that particulate emissions are likely to be higher during poor combustion periods such as occur during these times. The impact of startup and shutdown conditions on dioxin/furan emissions is unknown, but that provides little certainty for sources that will have to certify that they complied with the dioxin/furan limits during these periods. Since there is no significant averaging period provided for PM or dioxin/furan, any excursion during a startup or shutdown would presumably generate a deviation.

For pollutants other than CO, there is less information on how they behave during startup and shutdowns, but since those are inherently periods of poor combustion and unstable control operation, we would expect there to be some exceedances. For instance, the temperature of the stack gas going into the activated carbon absorption system will vary from ideal during startup and shutdown operations and thus mercury and dioxin removal will be less efficient than during normal operations.

Comment: The Agency also claims that startup and shutdowns are predictable and do not happen more than once per day. If emissions during startups and shutdowns are different than during normal operation, which they are, it doesn’t matter that the startup or shutdown was

predictable. The compliance average will still be impacted the same. The Agency's assumption that startups and shutdowns generally do not occur more than once per day is correct, though startups often take more than a day to complete and most take a significant part of a day. The number of startups in a day does not matter, however; what matters is the level of emissions during the startup or shutdown and the duration of those emissions relative to the averaging time of the standard. For CO, units with CEMS (units over 100 MMBTU/hr) having a 30 day averaging time, it only takes 1 day at 30 ppm to exceed the standard and such days will be the rule rather than the exception during boiler and process heater startups.

Commenter Affiliation: Morton Salt
Document Control Number: EPA-HQ-OAR-2002-0058-2883.1
Comment Excerpt Number: 24

Comment: EPA stated that CEMs data from best-performing units included periods of startup and shutdown, and therefore EPA's proposed standards are achievable.
To support its conclusion that the proposed emission standards should apply during all operational periods, including during SSM events, EPA asserts that startup and shutdown emissions replicate normal operation emissions. These conclusions are not supported by the record. EPA relied on continuous emission monitoring (CEMs) data obtained from best performing units, which EPA claims included periods of startup and shutdown. It is unclear whether this CEMs data actually warrants these conclusions. It does not appear that any of the units considered in the data collection were in startup or shutdown during the 30-day period of testing that EPA considered. Assuming that is the case, then the CEMs data does not demonstrate

that units can satisfy emissions limits over a 30-day period if all startup and shutdown events are included.
EPA is also operating on the misconception that solid fuel fired boilers do not normally start up and shutdown more than once per day and that startup and shutdown are part of routine operations and, therefore, are already addressed by the standards. 75 Fed. Reg. at 33,012. However, circumstances may necessitate multiple startups and shutdowns throughout a day for many boilers. The CAA has been interpreted to require that emissions standards be achievable under the most adverse conditions that can be expected to occur, not under assumptions of what is normally done or not done. EPA has not demonstrated startup and shutdown periods were actually considered even though the proposed rule establishes emissions standards that apply to units during steady-state operations as well as such periods.
Another concern is that EPA used 3-run stack test data, and not 30-day data, to set the proposed emissions floors. EPA has used test run data collected through the ICR phase II to establish proposed floors which reflect normal, often steady state, operating conditions. EPA's docket materials in support of the proposed rule even acknowledge that this data fails to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. This test data also does not utilize the CEMs data, including startup and shutdown information, in its variability analysis where it would be the most helpful in reflecting real-world fluctuations in emissions.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: The current decision by EPA to exclude startup, shutdown, and malfunction emissions records is technically unjustified. A series of previous emission control programs over the last 25 years has resulted in the installation of several systems to achieve specific emission reductions through targeted technologies, but most are designed for steady state or normal operations.
The first of these was implemented under the CAA revision of 1990 that required units larger than 25 MWe to reduce sulfur emissions below 1.2 lb/MMbtu and achieve at least a 90% reduction. One of the few methods of doing this that could survive severe abrasive characteristics present in some units was dry limestone injection. This process is dependent on injection of sized limestone into the furnace/boiler, calcinations of the limestone, and subsequent absorption of sulfur present in the flue gas. This process begins to occur at a useful rate at about 860 deg. F and is functional up to about 2200 deg. F. (Unfortunately at about 1640 deg. F thermal NOx generation normally inhibits operation above that temperature.) For a boiler to achieve the lower useful temperature of 860 deg. F, it must be heated up to that level, generally using natural gas or fuel oil. This thermal change to the materials that boilers are fabricated with is limited by

impacts of thermal stresses placed on both the generating tubes and drum materials, by the manufacturers to a change rate of 100 deg. F. Thus, to take a unit from cold to the functional temperature that limestone becomes effective for SO2 removal, takes a minimum of about 8 to 10 hours. Application of 'normal steady state' limits based on a temperature of 1600 deg. is not practical. Due to the high volume of combustion air involved, most casualties result in the unit falling outside of the optimum band for absorption also, so achievement of the limits during these periods is technically infeasible.

EPA has long recognized that control and/or monitoring equipment is not necessarily functional during SSM periods. In developing the SSM approach in the General Provisions, EPA recognized the difficulty of determining compliance during SSM periods. 58 Fed. Reg. 42,777 (Aug. 11, 1993). EPA adopted an approach whereby an owner of an affected facility who abides by a valid SSM plan during SSM periods would not be deemed in violation of the applicable standard. EPA stated:

This approach carries forward the requirement that control systems be operated at all times, but it allows special situations to occur, such as unpredicted and reasonably unavoidable failures of air pollution control systems, when it is technically impossible to properly operate these systems. 58 Fed. Reg. 42,777 (Aug. 11, 1993).

In the preamble to the final General Provisions, EPA responded to one commenter who said EPA should require affected sources to meet otherwise applicable emission limits during startups, shutdowns, and malfunctions. EPA said it believes, as it did at proposal, that the requirement for a startup, shutdown, and malfunction plan is a reasonable bridge between the difficulty associated with determining compliance with an emission standard during these events and a blanket exemption from emission limits. 59 Fed. Reg. 12,423 (Mar. 16, 1994). Morton Salt believes EPA's rationale is sound in this case, and it also applies to affected sources subject to the Boiler MACT standards and we fully support retaining this approach to startup, shutdown and malfunction in the final regulations.

Response: See the preamble changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: An Extended Averaging Period Will Not Eliminate Problems With Making Emissions Limits Applicable During Startup and Shutdown Periods

Institutional, commercial and industrial boilers require an extended period of startup during which most, if not all, equipment in the boiler and pollution control systems are not operating in their normal condition. Consequently, pollutant emission concentrations and emission rates can exceed those experienced during normal operation. It is very common in the boiler industry for certain control devices to be out of operation during periods of startup due to the nature of the equipment. During such periods it is likely that emissions will exceed the standards proposed and would never be able to recover to meet the average limitations. A more expanded discussion with respect to a few specific technologies is provided below. This extended startup period, typically several hours, is required due to equipment integrity concerns, limitations of the technologies, or safety concerns.

Equipment Integrity - As an example, a Fabric Filter (FF) cannot be put into service until the flue gas temperature is above the dewpoint for equipment integrity concerns. This requires that all heat transfer surfaces, ducts and flues from the combustion zone to the FF inlet be warmed up from ambient temperatures to dewpoint temperature (which varies by fuel type and fuel constituents, but is typically in excess of 140°F /60°C). It takes a considerable amount of time, typically several hours for larger units, to warm up this considerable mass of steel: waterwall tubes, superheater tubes, reheater tubes, economizer tubes, casings, turning vanes, air preheaters, ducts and inlet plenums. During this warmup period, the FF cannot be put into service without risking catastrophic failure of the bags and intensive corrosion damage to the FF due to acid dew point and other factors. This limits a unit's ability to control Particulate Matter and Mercury during the several hours of startup.

Limitations of the Technology - Limitations of the pollutant control technology also contribute to extended startup periods and excess emissions. Units equipped with a Spray Dryer Absorber (SDA) for acid gas removal are limited in the amount of reagent slurry that can be injected into the flue gas during startup. The slurry federate is limited due to the nature of the technology bythe amount of moisture the flue gas can evaporate. This, in turn, requires that a minimum temperature be achieved by the flue gas before the slurry federate can be initiated, and imposes a lengthy period of time during which the slurry federate is significantly limited until all the upstream heat transfer surface and ductwork has been warmed up. As such, SDA cannot remove Hydrogen Chloride in significant quantities for several hours after the unit is first fired.

Safety Concerns - Finally, safety concerns prevent operators from attempting to reduce the startup period. Reductions in the amount of time required to warm the boiler system up could be realized by increasing the ramp-rate of adding fuel to the unit. Although a boiler could potentially be brought from first flame to full load in a matter of minutes, decreasing the warm-up period from OEM recommendations risks severe metallurgical stresses due to rapid changes in temperature and wide variances in temperatures across the boiler and duct parts. Immediate failures could occur if inconsistent heating caused tears or ruptures in support steel or heat transfer surfaces, posing considerable risk to personnel in the plant. Failure rates would also increase due to the considerable stresses introduced by rapid heating and cooling cycles, yielding failures at unpredictable times. OEM recommendations for startup times are closely followed across industry for these reasons.

Comment: EPA makes a mistake with regard to its proposal not to set a separate standard for periods of startup, shutdown, and malfunction. On the one hand, EPA asserts that “[t]he standards we are proposing are daily or monthly averages ... [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards.”14 On the other hand, EPA uses short-term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction. To assure that startup, shutdown, and malfunction are appropriately accommodated, EPA must either assure that the data on which the standard is based include representative data from such periods or, alternatively, set a separate work practice standard to properly accommodate startup, shutdown, and malfunction.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: It must also be recognized that startups and shutdowns are often neither predictable nor routine. 75 FR at 33012. Industrial facilities, unlike electric utilities, typically operate a large number of smaller units of varying ages instead of operating a small number of very large units. When normal equipment failure rates such as tube leaks are multiplied across a large number of units, the total number of unit failures can be significantly larger at industrial facilities. It is not uncommon for unplanned outages to occur in clusters, such as when a given component, for example, an economizer might suffer a failure due to corrosion or erosion. Repairs may fix the failure at identified vulnerable areas nearby, but the root cause of the failure could be occurring in multiple areas that are not easily identified, resulting in additional failures in a short timeframe.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: EPA seeks to address the fact that units will not be able to comply with the proposed emissions standards by during startups and shutdowns by proposing extended daily or monthly

averaging periods. However, this assumption that longer averaging periods will provide a reasonable method to ensure compliance is flawed. Startup and shutdown periods vary in duration and intensity, a fact that can significantly impact actual emission profiles. Additionally, because unplanned outages are a reality in the operation of any boiler, industrial or utility, and because unplanned outages are by their nature unpredictable, unplanned shutdowns can and will cluster together. The calculation of a 30-day average fails to prevent deviations from emissions standards for multiple outages in the month following startup from a planned shutdown. A unit would be out of compliance because the rule as proposed includes no compliance protocol to address the fact that emissions performance during startups and shutdowns is not equivalent to emissions performance during steady-state operation.
Extended averaging periods are similarly inadequate to provide a reasonable method to demonstrate compliance with the CO standard, due to the inherent variability of CO in solid fuel boilers across the load range, but especially upon startup.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment Excerpt Number: 28

Comment: The Proposed Rule does not include a separate standard for startup and shutdown. This is a fundamental problem that, if not corrected, will cause the final standards to be unachievable by even well designed and operated boilers. As a result, EPA must include a separate standard for startup and shutdown in the final rule.
EPA explains in the preamble that, “Based upon continuous emission monitoring data, obtained as part of the information collection effort for the major source boiler and process heater rulemaking, which included periods of startup and shutdown, over long averaging periods, startups and shutdowns will not affect the achievability of the standards.” 75 FR at 31901. There are two fundamental problems with this justification for not including startup and shutdown standards in the rule.
First, EPA’s emissions database provides continuous emissions monitoring system (CEMS) data from several of the better performing sources. Contrary to EPA’s assertion in the preamble, these data show that daily average emissions should be expected to vary considerably on a day-to-day basis and that the variability spans the proposed levels of the standards. While it is difficult to discern the reasons for this variability based on the information provided in the database, there is little doubt that startups and shutdowns significantly contribute to the variable emissions performance of these units. Thus, the data indicate that EPA needs to include express accommodation for startups and shutdowns.
Second, basic scientific and engineering principles support the need for a separate standard for startup and shutdown. Particularly for CO emissions, combustion conditions will not be optimum during startup periods due to the generally low firing rate and the fact that the firing rate will be

ramped up over the startup period. Thus, a significant period of non-optimum firing conditions will result in CO emissions performance – even on a daily average basis – that will be markedly different than performance during normal operations. EPA's failure to acknowledge these basic technical and engineering principles renders the proposed standards arbitrary.
For these reasons, we believe that a separate standard for startup and shutdown is needed and is amply justified. We suggest that a work practice standard is most appropriate due to the lack of relevant data and the fact that an emission testing during startup is not technically and economically practicable. If EPA decides that a numeric standard is needed, the Agency should rely on the available long term data from the better performing boilers to establish a standard with a reasonably long averaging time (such as a 30-day rolling average), rather than the proposed 24-hour averaging time.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Instead of relying on extended averaging periods, Morton Salt believes that EPA should instead provide additional provisions to ensure emissions are minimized during startups and shutdowns without unreasonably requiring sources to attempt to comply with steady-state emission standards. EPA should add provisions to require sources to develop and adhere to operating practices specific to the unit's design, fuel type, and OEM recommendations that will ensure emissions minimization without forcing owner/operators to choose between putting their equipment and personnel at risk versus failing to comply with this rule. Such an operating practice should be crafted to be flexible, given the wide variety of boiler sizes, types, vintages, and fuels fired, and should be developed by the source based on OEM recommendations.
General guidelines could include:
* Sequencing of equipment startups, per OEM recommendations;
* Startup time durations, per OEM recommendations, and
* Provisions to clearly define what constitutes online versus startup. This could be crafted to mean a percentage of the unit's maximum continuous rating, or steam temperature/pressure, etc.
EPA should use operating practices during startup and shutdown to include general content relative to specific startup and shutdown sequences and time limits pending meeting emissions limits. Alternatively, if EPA uses a startup/shutdown standard, EPA should establish a broader averaging period that accounts for a wide range of emissions from startup and shutdown.

Comment Excerpt Number: 29

Comment: In addition to the unique operating characteristics of limited use boilers, there are practical reasons for creating a limited use subcategory as well. As noted by Judge Williams in Sierra Club v. EPA, "Section 112(d)(1) authorizes the Administrator to 'distinguish among classes, types, and sizes of sources within a category or subcategory' . . . . [O]ne legitimate basis for creating additional subcategories must be the interest of keeping the relation between 'achieved' and 'achievable' in accord with common sense and the reasonable meaning of the statute. Sierra Club v. EPA, 479 F.3d 875, 884-85 (D.C. Cir. 2007) (Williams, J., concurring).

Without subcategorization for limited use boilers, these infrequently operated units would need to comply with the same emission limits set by units that operate on a continuous bases. As noted above, "combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit's load (steam production) decreases." National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed.Reg. at 32023. Limited use boilers would therefore be operating for a significantly greater percentage of their time during periods of inefficient operation.

While EPA has already attempted to address this problem through the current MACT floor analysis by addressing the reduced efficiency of load-following units through allowances for variability,[See MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 9-10 (April 2010).] this problem is further amplified for limited use boilers, which EPA did not address in its MACT floor analysis, due to EPA's decision to include periods of startup and shutdown in determining compliance with MACT. As found by EPA, this was justified because "the standards that we are proposing are daily or monthly averages. Continuous emission monitoring data obtained from best performing units, and used in establishing the standards, include periods of startup and shutdown. Boilers, especially solid fuel-fired boilers, do not normally startup and shutdown more the [sic] once per day. Thus, we are not establishing a separate emission standard for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." Id. at 32013.[28 Continuous emission monitoring data is not available for all pollutants in the database. To the extent that emission limits are based on stack test data that does not consider SSM events, emission information based on an operator's knowledge and engineering calculations can be used to incorporate SSM variability into the MACT Floor analysis.]

Moreover, EPA found that "[p]eriods of startup, normal operations, and shutdown are all predictable and routine aspects of a source's operation." Id. Neither of these findings reasonably applies to emergency or backup boilers. First, as discussed above, emergency and backup boilers cannot practically make measurements over a monthly average given their limited utilization. Second, emergency and backup uses are by definition neither predictable nor routine.

By their very nature, emergency and backup boilers must spend a larger percentage of time in startup, shutdown, or other reduced-efficiency operating conditions than either base-loaded or load-following units. EPA should not require limited use boilers to comply with standards set by the best operated of these more efficient units.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Malfunctions Cannot Be Avoided - Even By Top Performers - and EPA Should Therefore Include the Use of Malfunction Plans.
EPA states in the proposed rule that if a source fails to comply with the applicable standard due to a malfunction event, EPA would determine an appropriate response. 75 FR 32,013. Many large sources have been required to submit Standard Operation and Malfunction Procedures under Title V concerning time limitations of malfunctions that impact emissions. These procedures were based on not exceeding monthly averages in the permit. Furthermore, the definition for malfunctions appears to be inappropriate considering that many malfunctions occur due to component failure and have nothing to do with poor maintenance or careless operation as defined in 40 C.F.R. 63.2.
Congress acknowledged that malfunctions cannot be prevented, and provisions allow for such occurrences. EPA also acknowledged that malfunctions cannot be prevented, even by top performers, and therefore defined a malfunction in the preamble of the proposed rule as a sudden, infrequent, and not reasonably preventable failure. Because EPA considered it difficult to set a standard for malfunction periods, EPA required all sources to comply with standards established for steady-state operation during periods of malfunction. This approach is unreasonable and inappropriately failed to include provisions that take into account the unpredictable nature of malfunctions, and that malfunctions occur to all units including top performers.

EPA should include additional provisions to accommodate the unpredictable and unavoidable malfunctions that both Congress and EPA acknowledged would occur. EPA should adopt a work practice of requiring malfunction plans to address potential equipment failures, provide troubleshooting and corrective actions, and other reasonable measures to minimize the duration of malfunctions and minimize emissions during unavoidable malfunctions. Using the plan and documenting actions in accordance with the plan would then constitute minimizing emissions via the general duty clause.

Response: See the preamble for achievability of limits and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-2941.1
Comment Excerpt Number: 32

Comment: EPA is proposing that boilers and process heaters with heat input capacities greater or equal to 100 MMBtu/hr "demonstrate that average CO emissions, on a 30-day rolling average, are at or below the proposed CO limit." National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed.Reg. at 32034. This averaging period is essential to accommodating expected data variability, including SSM events. See, e.g. National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters; Final Rule, 69 Fed.Reg. at 5521. See Response to Public Comments on Proposed Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP at 102 (rejecting a 24-hour averaging period because a 30-day rolling average "accounts for the variability in fuel characteristics (e.g., moisture, Btu content, mixture) that occur for solid fuel-fired boilers and process heaters"). Without the ability to test for 30 continuous days or thereabouts, a limited use boiler could not reasonably be expected to meet the same emission limits due to their reduced ability to accommodate data variability and operators cannot adequately determine compliance with numeric emission limits.

The result would be a marked inability to practically measure emissions without operating these units for significant periods of time for the sole purpose of conducting emissions testing. As with the recently regulated emergency CI RICE, this would result in a new increase in emissions through the very effort to control emissions from these units. See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, 75 Fed.Reg. at 9655-56. Work practices are therefore the most feasible control for limited use boilers and should be adopted in the new rule.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 32

Comment: EPA should apply work practice standards during periods of startup, shutdown, and malfunctions to appropriately recognize the operating and emission differences during these periods.

It is extraordinarily difficult if not impossible for boilers or process heaters to meet the proposed limits during startup (typically extended periods during which heating is done slowly to prevent damaging the heater) and, in some cases (e.g., when decoking or soot blowing is necessary) during shutdown.

EPA's failure to provide specific standards applicable to startup, shutdown, and malfunction (SSM) periods in the proposed Boilers and Process Heaters MACT is contrary to the statute's requirement that the standards established under section 112(d) be "achievable." See 42 U.S.C. section 7412(d)(2). Furthermore, EPA's claims that the proposed standards reflect startup and shutdown periods are not supported by the record. Because EPA has no data to support the application of the proposed emission limits during SSM, EPA should use its authority under section 112(h) to set work practice standards applicable during SSM.

To address the decision in Sierra Club v. EPA, 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010), which vacated the exemption in 40 C.F.R. section 63.6(f)(1) and (h)(1) for SSM periods, EPA proposes emissions standards in the Boilers and Process Heaters MACT that apply at all times, including periods of SSM. While the D.C. Circuit has ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112. See id. at 1028. In such cases, section 112(h) "work practices" or "operational" standards may be available. Id.

The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing NSPS under section 111 of the CAA, Portland Cement Ass'n v. Ruckelshaus, 486 F.2d 375, 398 (D.C. Cir. 1973), the court acknowledged that "'startup' and 'upset' conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." Id. at 399; see National Lime Ass'n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980) (noting that "a uniform standard must be capable of being met under most adverse conditions which can reasonably be expected to recur"). The D.C. Circuit acknowledged this same principle when reviewing emission standards for new sources in the medical waste incinerator rule under section 129 in Sierra Club v. EPA, 167 F.3d 658 (D.C. Cir. 1999). In that case, while the court did not find the record sufficient to support EPA's approach for new sources, the D.C. Circuit did not object to a standard-setting approach which would account for the performance of technology under the "worst reasonably foreseeable circumstances." See id. at 665. Furthermore, the D.C. Circuit reiterated the principle in National Lime that "where a statute requires that a standard be 'achievable,' it must be achievable 'under the most adverse circumstances which can reasonably be expected to recur.'" Id. at 665 (citing National Lime Ass'n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980)). EPA's MACT floor-setting approach in the proposed Boilers and Process Heaters MACT ignores these longstanding principles by applying the standards at all times, including SSM.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 33

Comment: EPA's proposal mischaracterizes the role of startup and shutdown data play in EPA's floor-setting process. EPA claims that the agency considered startup and shutdown periods when setting the floors because CEMS data, relied on by EPA in "establishing the standards," included data from those periods. 75 Fed. Reg. at 32,013. Despite this claim, however, EPA does not rely on the CEMS data when setting the floors for boilers and process heaters. To the contrary, as indicated by the ERG memorandum in the docket, EPA uses test run data collected through the ICR phase II testing process, which reflect normal operating conditions, to set the proposed floors. See Memorandum from A. Singelton, ERG, to J. Eddinger, U.S. EPA, MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 3 (April 2010). Thus, according to EPA's own docket materials, the data used to set the proposed floors fail to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Furthermore, as the ERG memorandum makes abundantly clear, EPA's approach does not make use of the CEMs data (with the startup and shutdown information) in its variability analysis where it would be the most helpful in reflecting real world fluctuations in emissions. Id.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 34

Comment: Given the lack of and difficulty collecting data for startup and shutdown emissions information, it is appropriate for EPA to set work practices for these events for boilers and process heaters. Section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard," defined as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." CAA section 112(h)(1)-(2); 42 U.S.C. section 7412(h)(1)(-2). Gathering data from startup and shutdown periods would be challenging given the brief nature of these periods as well as the need to define the exact time period for what is considered "startup" and/or "shutdown." Furthermore, a work practices approach for these periods would satisfy both the statute's requirement that MACT standards be "achievable" and the requirement that there be a MACT standard applicable at all times.

A work practices approach for these periods also would be consistent with EPA's recently promulgated MACT standards for compression ignition reciprocating internal combustion engines (CI-RICE). See National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines, Final Rule, 75 Fed. Reg. 9648 (Mar. 3, 2010). EPA finalized work practice standards for startup because the agency determined that it was "not feasible to finalize numerical emission standards that would apply during startup because the application of measurement methodology to this operation is not practicable due to technological and economic limitations." Id. at 9656. According to EPA, applicable test methods that would be needed to measure during these events "do not respond adequately to the relatively short term and highly variable exhaust gas characteristics occurring during these periods." Id. at 9665. Furthermore, EPA determined that the cost for testing all the engines affected by the rule to get the necessary data could be more than $1 billion. See id. Startup and shutdown periods for boilers encounter similar testing challenges and costs.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Douglas J. Van Pelt
Commenter Affiliation: ExxonMobil
Document Control Number: EPA-HQ-OAR-2002-0058-2968.1
Comment Excerpt Number: 35

Comment: EPA should set work practice standards to apply to malfunction periods. EPA acknowledges in the preamble to the proposed rule that it is "impracticable" to take periods of malfunctions into account when setting emissions standards given the "myriad different types of malfunctions that can occur across all sources in the category" and that "malfunctions can vary in frequency, degree, and duration, further complicating" the standard setting process. 75 Fed. Reg. at 32,013. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events. Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events.

With respect to malfunctions, EPA argues in the preamble to the proposed Boiler MACT that these periods should not be considered a "distinct operating mode" and uses this to justify not factoring these emissions into the proposed MACT standards. Considering that EPA's proposed MACT standards are supposed to apply at all times, the implication is that periods of malfunction also are covered by the MACT standards that apply during normal operations. This directly conflicts with the statutory requirement that the MACT standard be "achievable."

Given that the floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," EPA should set work practice requirements to address periods of malfunctions as well. Section 112(h) allows EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . . .” Similar to startup and shutdown, malfunctions fit with the situations described in the definition of “not feasible to prescribe or enforce an emission standard” as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. EPA acknowledges in the preamble to the proposed boiler rule that it is “impracticable” to take periods of malfunctions into account when setting emissions standards given the “myriad different types of malfunctions that can occur across all sources in the category” and that “malfunctions can vary in frequency, degree, and duration, further complicating” the standard setting process 75 Fed. Reg. at 32,013. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

Response: See the preamble for achievability of limits and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Document Control Number: EPA-HQ-OAR-2002-0058-2777.1
Comment Excerpt Number: 39

Comment: International Paper supports the fact that facilities do not have to develop and implement a Startup, Shutdown, and Malfunction (SSM) Plan nor submit periodic and immediate SSM reports.

SSM plans, Periodic SSM reports and Immediate SSM reports are no longer required per Table 10 of the proposed rule due to the SSM vacatur. EPA specifically requested comment on this point (75 FR 32012). International Paper agrees that no SSM plans or SSM recordkeeping and reporting provisions are warranted. If the limits are to apply at all times, however, as previously stated the proposed MACT limits do not account for SSM and therefore the standards should not apply during SSM periods. Instead, EPA should consider work practice standards during periods of SSM, as further detailed in AF&PA’s comments.

Comment: EPA makes a similar mistake with regard to its proposal not to set a separate standard for periods of startup, shutdown, and malfunction. On the one hand, EPA asserts that "[t]he standards we are proposing are daily or monthly averages … [t]hus, we are not establishing separate emission standards for these periods because startup and shutdown are part of their routine operations and, therefore, are already addressed by the standards." On the other hand, EPA uses short term performance test results to set the standards rather than the results of long-term CEMS monitoring. As a result, the emissions data on which the standards are based do not, in fact, reflect or adequately accommodate emissions from periods of startup, shutdown, or malfunction.

Comment: Startup, Shutdown, Malfunction. Under the proposed rule, there are no exemptions for startups, shutdowns or malfunctions (SSMs). EPA must recognize that the boilers at Maine Mills (and generally in the industry) do not run at steady state and that the proposed standards cannot be met while starting up and shutting down boilers. Startup, shutdowns and malfunctions should be exempt or the standards should be set for long-term averages that take into account the variations seen in SSM events.

Response: See the preamble for changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: Startup periods are not predictable and should not be included in the emissions averaging period. We recommend that startup periods be treated outside the averaging period similar to "periods of malfunction" (CAA section 112(d)).

The combustion of biomass has its challenges. Biomass has a low calorific value and high moisture content when compared to fossil fuels. Biomass characteristics can vary significantly based on a number of factors, including species, geographic origin, and time of year. Thus, there is variability in biomass that is not inherent to the combustion of fossil fuels. This variability along with the extreme dynamics associated with startups of a biomass fired boiler make it unreasonable to include them in the emissions compliance averaging period. The proposed ruling states that “Periods of startup, normal operations, and shutdown are all predictable and routine aspects of a source’s operation.” We have not found this to be the case in practice when it comes to biomass combustion. The variability in biomass makes it difficult to standardize an optimized mode of operation on a consistent basis, particularly during startup conditions. Thus, emission control during startup is anything but predictable and consistent. The source data supports this. The data presented for CO emissions fluctuate significantly during the performance testing period. Metso believes that no technology is commercially available, including oxidation catalysts, to control emissions of CO during startup or shutdown to the degree that would be required to satisfy the proposed rulings. These variations are further complicated by the fact that many units are not based-loaded and must deal with fluctuations in load that will create transient conditions, even during normal operation. This can result in frequent operating instabilities lasting several hours. compounding the unpredictable nature of biomass combustion and the resulting emissions.

Comment: EPA should include provisions for start-ups and shutdowns. Wood and multi-fueled fired boilers produce large CO variations during startups as the boilers heat up. Start-up can take up to 14 hours for some units. Shutdowns can also result in significant CO variability.

Comment: EPA does not provide achievable limits or an alternative for a work practice for boiler start-ups, shutdowns or malfunctions (i.e., during “SSM” events). For example, during biomass boiler start-ups when temperatures are low and boiler load rate is low, CO emissions also are elevated; as the trade group comments note, this is in part due to elevated oxygen levels during start-up, which translate to very high O2-adjusted CO emission rates that are in the form required for comparison to the limit.

Comment: EPA Should Not Treat HAP Emissions During Startup and Shutdown the Same as HAP Emissions During Normal Operation. The IB ICR did not require any testing during start-up, shutdown and malfunction events. Without emissions data during these periods, EPA has no factual basis for concluding that the best performing units can achieve the proposed MACT limits during start-up, shutdown and malfunction events. Operations during boiler startups are different than normal plant operations. Certain plant components must be started in a specific sequence in order to ensure that steady state operations can be achieved. During start-up, not all pieces of control equipment will be operating at peak efficiency. The FCG urges EPA to exempt these events based on the lack of data availability and its unrestricted operational control. In addition, FCG believes that startup, shutdown and malfunction events should be excluded from all emission averaging requirements in the IB MACT proposal. These events were not included in the ICR data gathering used to develop the emission standards, thus many of the proposed standards will be impossible to meet if these periods are included in the averaging periods.

Comment: Startup, Shutdown, and Malfunction Requirements Are Unrealistic. The EPA proposal specifies that the proposed emission limits apply during periods of startup, shutdown, and malfunction. In support of this proposal, EPA states that startup and shutdown emissions are equivalent to normal operation emissions based on continuous emission monitoring data obtained from best performing units that included periods of startup and shutdown. However, the test data does not show a sufficiently representative sampling of startup, shutdown, and malfunction conditions that represent their duration and variety of characteristics. By considering these periods to be part of "routine operations" EPA ignored the circumstances that justify the establishment of work practices or emission limits that would apply in such situations.

Comment: EPA should clarify that startup, shutdown and malfunction plans and associated reporting are not required.

In Table 9 of the proposed rule, items 1(d) and 2 delineate requirements regarding startup, shutdown, and malfunction (SSM) plans and reporting. However, EPA indicates it is changing SSM requirements in response to recent Court decisions, and multiple citations in Table 10 of the proposed rule indicate that SSM plans and associated reporting are not required. These two tables are contradictory. Items 1(d) and 2 from Table 9 should be deleted.

Comment: Steady State vs. Startup and Shutdown Scenarios
There is significant variation in the amount and duration of startup, shutdown and malfunction (SSM) emissions for various fuels. NIIDES anticipates that variations in SSM emissions would be greater for boilers firing solid fuels such as biomass, than for boilers firing liquid fuels such as heating oil. NHDES recommends that EPA consider setting 30-day averaging times for solid fuel boilers. In order to refine both the emission limits and averaging times, EPA should collect SSM data from CEMs installed at the facilities previously included in the MACT ICR. In addition, EPA should use portable analyzers to evaluate SSM emissions at smaller boilers in the ICR that do not have CEMs concurrently during future compliance testing. This should give EPA sufficient information within five years from promulgation of the regulation to develop appropriate limits and averaging times for SSM emissions.

Comment: While the Maine DEP recognizes that the courts decreed that emission standards established under the Clean Air Act must apply at all times, EPA must still consider the practical limitations of implementing this directive. In reality, during periods of startup and shutdown, all types of boilers emit more pollutants than during steady state operations. This is particularly true for biomass boilers, where the fuel is introduced onto the combustion chamber more gradually during start up and ceases combustion more gradually than liquid or gaseous fuels. Maine's experience is that the amount of time to reach the desired steady state for minimizing emissions depends on a number of factors such as the design of the system, its size, and the type of fuel that is combusted. The Maine DEP also recognizes that insufficient data is currently available to establish alternative emission standards for start-up and shutdown period. Therefore, we recommend that EPA require facilities to develop and implement plans to minimize the amount of time for startup and shut-downs and to minimize the amount of pollutants emitted during these periods. Accompanying emission standards with long averaging periods will ensure that overall emissions from affected units are minimized.

Comment: EPA has chosen to assume for the proposed rule that emissions during SSM events are either (a) already incorporated into the emission limits they proposed based on a view that at least some of the stack test data in the database adequately represent such periods, or (b) the averaging periods EPA proposes provide sufficient room to smooth out emission spikes during those events so that compliance can be planned and engineered.

Based on our experience with boiler emissions during SSM events, we believe EPA's assumptions will prove inadequate in many cases, putting our sources at compliance risk for events that EPA failed to adequately consider in the MACT floors. We refer EPA to the very extensive technical discussions and quantitative proofs contained in the trade group comments reaching the same conclusion. Those comments demonstrate how such events are not adequately included in the database nor are existing combustion units capable of meeting the emission limits, especially for CO and PM, even when longer averaging periods are provided. For example, boiler start-up conditions typically produce elevated CO emissions that may exceed the limits even for "best performers" that are subject to a 30-day averaging period for compliance (i.e., when a CO CEMS is required for boilers of 100 mmBtu or more). At some of our wood products mills biomass boilers are currently operated on a four or five day schedule, so start-ups and shutdowns occur twice a week, making this a routine concern.

As a remedy, we encourage EPA to consider establishing work practices to address emissions during these SSM periods, but urge EPA while doing so to take care not to create redundant new regulatory burdens (i.e., either work in concert with or exempt from, the current Part 63 General Provisions that address the minimization of emissions consistent with safety and good combustion practices). We refer EPA to the AWC and AF&PA comments for detailed discussion of the legal requirement for addressing SSM periods so that the standards established under CAA 112(d) are "achievable." In the longer term EPA could collect the data to ensure that such events are truly represented in the database before establishing emission limits including SSM periods.

Comment Excerpt Number: 25

Comment: EPA proposes to regulate emissions of HAPs from boilers during all phases of operations, including startup, shutdown, and malfunction (SSM) periods. We are unsure how EPA has accounted for these emissions within the proposed emission limits, as the current data do not include such emission measurements. Furthermore, there is significant variation in the amount and duration of SSM emissions for various fuels and sizes of boilers. For example, we anticipate that variation in SSM emissions would be greater when using boilers firing solid fuels, such as biomass, than with boilers firing liquid fuels such as heating oil. NESCAUM recommends that EPA use facilities regulated under this effort to collect SSM emissions data and then revisit this issue no later than five years from promulgation to develop appropriate limits for SSM emissions. Facilities that measure emissions with CEMS could provide the basis for developing emission limits for SSM periods. In addition, EPA should examine how to evaluate SSM emissions at smaller boilers that do not have CEMS, and how those facilities could evaluate those emissions during compliance testing.

Comment Excerpt Number: 41

Comment: EPA has not properly accounted for startup, shutdown, and malfunction conditions in the proposed emission standards.

EPA states that it obtained CEMS data from best performing units and used this data in establishing the standards. EPA further states that these periods are predictable and routine and it believes it is appropriate to have the same standards apply during startup and shutdown as applied to normal operation.

EPA has not established in the record that these statements and conclusions are true. The MACT floor standards were derived entirely from CO performance test (3-runs) data. While EPA did attempt to address variability by gathering 30 days of CO CEMS data from five boilers, it did not utilize this data other than to conclude that only the two biomass boilers showed an inverse relationship of CO to boiler load (see page 9 of the MACT floor memorandum) and to conclude that the statistical methodology using solely performance test data was appropriate.

Eastman notes that not all these data sets include periods of startup. In the stoker coal subcategory, the unit at DuPont in West Virginia did not note any periods of SSM in the CO Monitoring Template. Further, EPA's graph of the CO CEMS data plotted vs boiler load for the Phillip Morris boiler in Virginia (the only pulverized coal boiler with CEMS data in EPA's dataset) (see Appendix B-1 of the MACT floor memorandum) is wrong (it appears to plot the Excel row number vs. CO) and does not include data from boiler load below 100 mmBtu/hr. Included in Figure 2 of the submittal is the correct graph of this information. This boiler went through three startups during the 30 day period and the graph clearly shows elevated CO during low load periods and shows an inverse relationship of CO and boiler load. The average CO concentrations during periods of only “normal” operations was 35 ppm whereas the average CO concentrations during all periods (normal, shutdown, startup) was 27 ppm.

Comment: For the coal subcategory, EPA has not correctly assessed the impact of startups and shutdowns on 30 day rolling average CO concentrations. In the case of the stoker coal subcategory, no data from startups and shutdowns were included in EPA’s analysis. In the case of the pulverized coal subcategory, EPA’s analysis erroneously excluded startup periods from the one unit which has CEMS data. Additional data must be gathered before EPA can conclude that a standard based solely on 3-run performance tests can be met by the top performers using a 30 day rolling compliance period.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Commenter Name: Stephen R. Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3137.1
Comment Excerpt Number: 45

Comment: EPA has not addressed the PM standard as to whether or not the proposed standard is achievable by the top performers during SSMs. Since periodic stack gas performance tests do not include periods of SSM, most units will have no data upon which to determine if they are complying with the emission standard at all times. However, certain boilers over 250 mmBtu/hr heat input rating would have PM CEMS to demonstrate compliance with the PM standard on a daily average basis. EPA has not collected data to determine if the top performers can achieve the emission standard during SSMs on a daily average basis. As discussed below, there are cases where boilers can have higher emissions during a startup period than during steady-state operation:

Fabric Filters (FF) installed for particulate matter (PM) control are designed to operate at steady state conditions where the flue gas temperature is well above the dewpoint temperature. If flue gas at or below the dewpoint temperature is passed through a FF, a phenomenon called "blinding" of the bags will occur. "Blinding" of the bags occurs when ash, either already embedded in a bag that has been previously in service, or ash entrained in the flue gas, is wetted and embeds itself into the fibers of the bags in such a manner as to permanently restrict the flow of flue gas. Bags that have been "blinded" are unable to pass their rated volumetric flow of flue gas, resulting in boiler derating, and poor PM removal, and are prone to sudden failure. Bags that have been badly "blinded" are not able to remain in service, and require an unplanned shutdown and replacement. As with any unplanned outage due to failure, the lead time and cost of replacement parts (several hundred or thousands of bags for a FF) is significant. Additionally, when gas at or below its dewpoint temperature is passed through a FF, the interior surface of the metal casing would be subject to widespread and aggressive corrosion. As an example of how significant this failure mode is viewed to be by OEM's, most boilers that have FF installed downstream of semi-dry scrubbers (e.g., Spray Dryer Absorbers, or SDAs) have elaborate control systems designed to limit how low the temperature of the flue gas entering the FF can go, specifically to protect the FF from blinding bags or incurring excessive damage due to corrosion.

Large utility boilers equipped with FF for particulate control typically have very large FFs, with multiple compartments, or multiple FFs each with multiple compartments. Such configurations allow the utility the option to designate one compartment as a "sacrificial compartment" during each startup and shutdown event. A "sacrificial compartment" is the one compartment which is designated to see flue gas that is very close to the dewpoint. The remaining compartments are only returned to service after the flue gas has reached a minimum temperature judged to be safely above the dewpoint. This limits the unit's risk of bag failures and corrosion damage to a single compartment. Smaller institutional, commercial and industrial boilers, by contrast, do not always have the luxury of very large FFs with many compartments, and thus cannot limit their risk of widespread bag failures and corrosion damage. In this regard, the industrial boiler community faces a technical challenge that is unique due to their smaller size.

EPA should include additional provisions in this rule to address PM compliance during startups and shutdowns for boilers equipped with FFs. Institutional, Commercial and Industrial boilers should be allowed to comply with a different standard during periods of startup and shutdown, or be allowed to develop startup and shutdown plans specific to the individual unit and its startup fuel(s) that control emissions without subjecting the equipment to recurring costly failures.

Commenter Name: Britt S. Fleming
Commenter Affiliation: Auto Group
Document Control Number: EPA-HQ-OAR-2002-0058-2775.1
Comment Excerpt Number: 50

Comment: In § 63.7505(a) of the proposed Boiler MACT rule, sources would be subject to emission limits and operating limits at all times. [Footnote: See id. at 32,050.] This would mean that units using landfill gas would have to comply with the emission limits under any and all conditions. EPA's proposed approach to addressing startup, shutdown, and malfunction (SSM) periods for other gas units in the Boiler MACT is contrary to the statute's requirement that the standards established under section 112(d) be "achievable." [Footnote: See CAA 112(d)(2); 42 U.S.C. § 7412(d)(2).] Furthermore, EPA's claims that the MACT standards reflect startup and shutdown periods are not supported by the record.

To address the decision in Sierra Club v. EPA, [Footnote: 551 F.3d 1019 (D.C. Cir. 2008), cert. denied, 2010 U.S. LEXIS 2265(2010).] which vacated the exemption in 40 C.F.R. § 63.6(f)(1) and (h)(1) for SSM periods, EPA proposes emissions standards in the MACT for boilers and process heaters that apply at all times, including periods of SSM. EPA claims in the preamble that startup and shutdown periods were taken into consideration when setting the MACT standards. [Footnote: See 75 Fed. Reg. at 32,012-13.] According to the preamble, CEM data from the best performing units, which include startup and shutdown periods, are used to set the floor levels in the proposed rule. [Footnote: See 75 Fed. Reg. at 32,012-13.] EPA further notes that startup and shutdown are part of "routine operations" and are therefore "already addressed" in the MACT standards. While the Auto Group agrees with EPA that startup and shutdown are part of routine operations, these periods have not been adequately addressed by EPA's proposed emission limits or analyzed properly when setting the floors. As discussed below, work practices should be established to accommodate startup and shutdown periods.

With regard to malfunctions, however, EPA states that these periods should not be viewed as a "distinct operating mode," and thus, emissions from these periods do not need to be factored into developing the MACT floor levels. Moreover, EPA states that even if malfunctions were to be considered a distinct operating mode, it would be "impracticable to take malfunctions into account in setting CAA section 112(d) standards for major source boilers and process heaters" given that these episodes are by definition sudden and unexpected events which vary in degree, frequency, and duration. The Auto Group agrees that it would be impracticable to establish emission limits for malfunctions as they vary in degree, frequency and duration. As discussed in detail below, work practices also should be established to accommodate malfunction periods.

When setting standards in the early 1990's under CAA section 112(d), EPA used its New Source Performance Standards (NSPS) program as a model. The section 112 standards were acknowledged by EPA to be "essentially equivalent to [section 111] performance standards" and that "unpredicted and reasonably unavoidable failures of air pollution control systems" would occur. [Footnote: See 58 Fed. Reg. 42,760, 42,777 (Aug. 11, 1993).] To address this situation, EPA adopted a similar exemption to the one in the NSPS Program for SSM events and imposed a "general duty" to minimize emissions. Thus, EPA acknowledged, as early as 1993, that SSM events are not appropriate for inclusion in a MACT standard and that an alternative approach should be used to address these situations. While the D.C. Circuit has ruled that sources cannot be exempt from complying with MACT standards, the court noted that Congress recognized in some instances that it may not be feasible to prescribe or enforce an emission standard under section 112, and so section 112(h) "work practices" or "operational" standards are available in certain limited situations. [Footnoe: See Sierra Club v. EPA, 551 F.3d at 1028.]

The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. For example, in a case reviewing NSPS under section 111 of the CAA, Portland Cement Ass'n v. Ruckelshaus, [Footnote: 486 F.2d 375, 398 (D.C. Cir. 1973).]the court acknowledged that "'startup' and 'upset' conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." [Footnote: Portland Cement Ass'n v. Ruckelshaus, 486 F.2d at 399.] Furthermore, in National Lime Ass'n v. EPA, [Footnote: 627 F.2d 416 (D.C. Cir. 1980).] the court noted that "a uniform standard must be capable of being met under most adverse conditions which can reasonably be expected to recur." [Footnote: National Lime Ass'n v. EPA, 627 F.2d at 431 n.46.] The D.C. Circuit acknowledged this same principle almost 20 years later when reviewing emission standards for new sources in the medical waste incinerator rule under section 129 in Sierra Club v. EPA. [Footnote: 167 F.3d 658 (D.C. Cir. 1999).] In that case, while the court did not find the record sufficient to support EPA's approach for new sources, the D.C. Circuit did not object to a standard-setting approach which would account for the performance of technology under the "worst reasonably foreseeable circumstances." [Footnote: Sierra Club v. EPA, 167 F.3d at 665.] Furthermore, the D.C. Circuit reiterated the principle in National Lime that "where a statute requires that a standard be 'achievable,' it must be achievable 'under the most adverse circumstances which can reasonably be expected to recur.'" [Footnote: Id. at 665 (citing National Lime Ass'n v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980)).]

EPA's MACT floor-setting approach in the proposed Boiler MACT ignores these longstanding principles and mischaracterizes the role startup and shutdown data play (or rather, does not play, as the case is here) in EPA's floor-setting process. As noted above, EPA claims that the agency considered startup and shutdown periods when setting the floors because CEMs data, relied on by EPA in "establishing the standards," included data from those periods. [Footnote: See 75 Fed. Reg. at 32,012.] Despite this claim, however, EPA does not rely on the CEMs data when setting the floors for boilers and process heaters. To the contrary, as indicated by the ERG memorandum in the docket, EPA uses test run data collected through the ICR phase II testing process, which reflect normal (often steady state) operating conditions, to set the proposed floors. [Footnote: See Memorandum from A. Singelton, ERG, to J. Eddinger, U.S. EPA, MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 3 (April 2010).] Thus, according to EPA's own docket materials, the data used to set the proposed floors fail to account for the dynamic conditions and variable emissions occurring during startup and shutdown episodes. Furthermore, as the ERG memorandum makes abundantly clear, EPA's approach does not make use of the CEMs data (with the startup and shutdown information) in its variability analysis. [Footnote: See Memorandum from A. Singelton, ERG, to J. Eddinger, U.S. EPA, MACT Floor Analysis (2010) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source at 3 (April 2010).]

Comment: Even if EPA were to include the 30 day CEMs data in setting the emission limits for the Gas 2 subcategory, it is not clear that the 30 day CEMs data is representative of sources that experience frequent startup and shutdown events. For example, a facility that uses process steam and is only operating one shift per day may shutdown the boiler at the end of each shift to reduce operating expenses and conserve resources. If a source measures high CO emissions for a brief period of time during startup and shutdown of that unit, it may take several days—and perhaps a whole month—for the average to fall below the proposed limit. This effectively would compel the source to idle the boiler instead of shutting it down in order to ensure compliance with the very low emission limits. Such a result is contrary to common sense and conflicts with the goals of reducing fuel consumption and emissions.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.

Comment: In addition, CEMs are not an appropriate way to measure emissions during SSM events. Specifically, CEMs are certified using reference test methods that require near steady state operation. RATA testing requires near steady state operation for 21 minute intervals and is performed only after a boiler has reached normal operating conditions. The conditions that occur during SSM events are anything but steady state and therefore there would be no way to verify with a RATA test that the CEMs is operating properly.

From an economic perspective, the use of CEMs to measure emissions during SSM events is not feasible. First, facilities do not have CEMs on every boiler or process heater at a facility and, therefore, the equipment would need to be installed on multiple units at the affected facilities. The cost of installing a CEMs is considerable. One vendor estimate indicates that the total installed cost can range from $35,000-45,000 per unit. This includes the cost for the sample line, sample probe, rack, analyzers, data collection and engineering. In addition to these costs, there also are operating expenses for the equipment that can run from $24,000-$34,000 annually per CEMs. This amounts to a significant cost for an affected source for equipment that is not even demonstrated as an accurate way to measure during SSM events. Furthermore, for those CEMs that already are installed, EPA’s proposed emission limits would necessitate an additional range to monitor compliance. This would mean additional equipment would be needed just for this rule, which would require additional installation and operational costs as well for existing CEMs. Considering that a vast majority of facilities have multiple affected units, the use of CEMs is not economically feasible.

Response: See the preamble for response to how EPA adjusted CO emission limits and compliance mechanisms, and changes made in the final rule to address concerns with start-up, shutdown, and malfunction.
